File 1 - __init__.py:

```
1: (0)              """
2: (0)              An object-oriented plotting library.
3: (0)              A procedural interface is provided by the companion pyplot module,
4: (0)              which may be imported directly, e.g.::
5: (4)                  import matplotlib.pyplot as plt
6: (0)              or using ipython::
7: (4)                  ipython
8: (0)              at your terminal, followed by::
9: (4)                  In [1]: %matplotlib
10: (4)                 In [2]: import matplotlib.pyplot as plt
11: (0)             at the ipython shell prompt.
12: (0)             For the most part, direct use of the explicit object-oriented library is
13: (0)             encouraged when programming; the implicit pyplot interface is primarily for
14: (0)             working interactively. The exceptions to this suggestion are the pyplot
15: (0)             functions `.pyplot.figure`, `.pyplot.subplot`, `.pyplot.subplots`, and
16: (0)             `.pyplot.savefig`, which can greatly simplify scripting.  See
17: (0)             :ref:`api_interfaces` for an explanation of the tradeoffs between the implicit
18: (0)             and explicit interfaces.
19: (0)             Modules include:
20: (0)             :mod:`matplotlib.axes`
21: (4)                 The `~.axes.Axes` class.  Most pyplot functions are wrappers for
22: (4)                 `~.axes.Axes` methods.  The axes module is the highest level of OO
23: (4)                 access to the library.
24: (0)             :mod:`matplotlib.figure`
25: (4)                 The `.Figure` class.
26: (0)             :mod:`matplotlib.artist`
27: (4)                 The `.Artist` base class for all classes that draw things.
28: (0)             :mod:`matplotlib.lines`
29: (4)                 The `.Line2D` class for drawing lines and markers.
30: (0)             :mod:`matplotlib.patches`
31: (4)                 Classes for drawing polygons.
32: (0)             :mod:`matplotlib.text`
33: (4)                 The `.Text` and `.Annotation` classes.
34: (0)             :mod:`matplotlib.image`
35: (4)                 The `.AxesImage` and `.FigureImage` classes.
36: (0)             :mod:`matplotlib.collections`
37: (4)                 Classes for efficient drawing of groups of lines or polygons.
38: (0)             :mod:`matplotlib.colors`
39: (4)                 Color specifications and making colormaps.
40: (0)             :mod:`matplotlib.cm`
41: (4)                 Colormaps, and the `.ScalarMappable` mixin class for providing color
42: (4)                 mapping functionality to other classes.
43: (0)             :mod:`matplotlib.ticker`
44: (4)                 Calculation of tick mark locations and formatting of tick labels.
45: (0)             :mod:`matplotlib.backends`
46: (4)                 A subpackage with modules for various GUI libraries and output formats.
47: (0)             The base matplotlib namespace includes:
48: (0)             `~matplotlib.rcParams`
49: (4)                 Default configuration settings; their defaults may be overridden using
50: (4)                 a :file:`matplotlibrc` file.
51: (0)             `~matplotlib.use`
52: (4)                 Setting the Matplotlib backend.  This should be called before any
53: (4)                 figure is created, because it is not possible to switch between
54: (4)                 different GUI backends after that.
55: (0)             The following environment variables can be used to customize the behavior:
56: (0)             :envvar:`MPLBACKEND`
57: (4)                 This optional variable can be set to choose the Matplotlib backend. See
58: (4)                 :ref:`what-is-a-backend`.
59: (0)             :envvar:`MPLCONFIGDIR`
60: (4)                 This is the directory used to store user customizations to
61: (4)                 Matplotlib, as well as some caches to improve performance. If
62: (4)                 :envvar:`MPLCONFIGDIR` is not defined, :file:`{HOME}/.config/matplotlib`
63: (4)                 and :file:`{HOME}/.cache/matplotlib` are used on Linux, and
64: (4)                 :file:`{HOME}/.matplotlib` on other platforms, if they are
65: (4)                 writable. Otherwise, the Python standard library's `tempfile.gettempdir`
66: (4)                 is used to find a base directory in which the :file:`matplotlib`
67: (4)                 subdirectory is created.
```

```
(0)             Matplotlib was initially written by John D. Hunter (1968-2012) and is now
(0)             developed and maintained by a host of others.
(0)             Occasionally the internal documentation (python docstrings) will refer
(0)             to MATLAB®, a registered trademark of The MathWorks, Inc.

213: (4)                """
214: (4)                Configure Matplotlib's logging levels.
215: (4)                Matplotlib uses the standard library `logging` framework under the root
216: (4)                logger 'matplotlib'.  This is a helper function to:
217: (4)                - set Matplotlib's root logger level
218: (4)                - set the root logger handler's level, creating the handler
219: (6)                  if it does not exist yet
220: (4)                Typically, one should call ``set_loglevel("info")`` or
221: (4)                ``set_loglevel("debug")`` to get additional debugging information.
222: (4)                Users or applications that are installing their own logging handlers
223: (4)                may want to directly manipulate ``logging.getLogger('matplotlib')`` rather
224: (4)                than use this function.
225: (4)                Parameters
226: (4)                ----------
227: (4)                level : {"notset", "debug", "info", "warning", "error", "critical"}
228: (8)                    The log level of the handler.
229: (4)                Notes
230: (4)                -----
231: (4)                The first time this function is called, an additional handler is attached
232: (4)                to Matplotlib's root handler; this handler is reused every time and this
233: (4)                function simply manipulates the logger and handler's level.
234: (4)                """
235: (4)                _log.setLevel(level.upper())

269: (4)                """
270: (4)                Get the version of some executable that Matplotlib optionally depends on.
271: (4)                .. warning::
272: (7)                   The list of executables that this function supports is set according to
273: (7)                   Matplotlib's internal needs, and may change without notice.
```

```
    Parameters
    ----------
    name : str
        The executable to query.  The following values are currently supported:

        "dvipng", "gs", "inkscape", "magick", "pdftocairo", "pdftops".  This
        list is subject to change without notice.
    Returns
    -------
    tuple
        A namedtuple with fields ``executable`` (`str`) and ``version``
        (`packaging.Version`, or ``None`` if the version cannot be determined).
    Raises
    ------
    ExecutableNotFoundError
        If the executable is not found or older than the oldest version
        supported by Matplotlib.  For debugging purposes, it is also
        possible to "hide" an executable from Matplotlib by adding it to the
        :envvar:`_MPLHIDEEXECUTABLES` environment variable (a comma-separated
        list), which must be set prior to any calls to this function.
    ValueError
        If the executable is not one that we know how to query.

(8)                 key: [(rcsetup._auto_backend_sentinel if key == "backend" else
(15)                       rcParamsDefault[key]),
(14)                      validator]
(8)                 for key, validator in rcsetup._validators.items()}
(0)         if rcParams['axes.formatter.use_locale']:
(4)             locale.setlocale(locale.LC_ALL, '')
(0)         def rc(group, **kwargs):
(4)             """
(4)             Set the current `.rcParams`.  *group* is the grouping for the rc, e.g.,
(4)             for ``lines.linewidth`` the group is ``lines``, for
(4)             ``axes.facecolor``, the group is ``axes``, and so on.  Group may
(4)             also be a list or tuple of group names, e.g., (*xtick*, *ytick*).
(4)             *kwargs* is a dictionary attribute name/value pairs, e.g.,::
(6)               rc('lines', linewidth=2, color='r')
(4)             sets the current `.rcParams` and is equivalent to::
(6)               rcParams['lines.linewidth'] = 2
(6)               rcParams['lines.color'] = 'r'
(4)             The following aliases are available to save typing for interactive users:
(4)             =====   =================
(4)             Alias   Property
(4)             =====   =================
(4)             'lw'    'linewidth'
(4)             'ls'    'linestyle'
(4)             'c'     'color'
(4)             'fc'    'facecolor'
(4)             'ec'    'edgecolor'
(4)             'mew'   'markeredgewidth'
(4)             'aa'    'antialiased'
(4)             =====   =================
(4)             Thus you could abbreviate the above call as::
(10)                  rc('lines', lw=2, c='r')
(4)             Note you can use python's kwargs dictionary facility to store
(4)             dictionaries of default parameters.  e.g., you can customize the
(4)             font rc as follows::
(6)               font = {'family' : 'monospace',
(14)                      'weight' : 'bold',
(14)                      'size'   : 'larger'}
(6)               rc('font', **font)  # pass in the font dict as kwargs
(4)             This enables you to easily switch between several configurations.  Use
(4)             ``matplotlib.style.use('default')`` or :func:`~matplotlib.rcdefaults` to
```

```
(4)                 restore the default `.rcParams` after changes.
(4)                 Notes
(4)                 -----
(4)                 Similar functionality is available by using the normal dict interface,
i.e.
(4)                 ``rcParams.update({"lines.linewidth": 2, ...})`` (but ``rcParams.update``
(4)                 does not support abbreviations or grouping).
(4)                 """
(4)                 aliases = {
(8)                     'lw':  'linewidth',
(8)                     'ls':  'linestyle',
(8)                     'c':   'color',
(8)                     'fc':  'facecolor',
(8)                     'ec':  'edgecolor',
(8)                     'mew': 'markeredgewidth',

(4)             --------
(4)             :ref:`customizing-with-matplotlibrc-files`
(4)             Examples
(4)             --------
(4)             Passing explicit values via a dict::
(8)                 with mpl.rc_context({'interactive': False}):
(12)                    fig, ax = plt.subplots()
(12)                    ax.plot(range(3), range(3))
(12)                    fig.savefig('example.png')
(12)                    plt.close(fig)
(4)             Loading settings from a file::
(9)                  with mpl.rc_context(fname='print.rc'):
(13)                     plt.plot(x, y)  # uses 'print.rc'
(4)             Setting in the context body::
(8)                 with mpl.rc_context():
(12)                    mpl.rcParams['lines.linewidth'] = 5
(12)                    plt.plot(x, y)
(4)             """
(4)             orig = dict(rcParams.copy())
(4)             del orig['backend']
(4)             try:
(8)                 if fname:
(12)                    rc_file(fname)
(8)                 if rc:
(12)                    rcParams.update(rc)
(8)                 yield
(4)             finally:
(8)                 dict.update(rcParams, orig)  # Revert to the original rcs.
(0)         def use(backend, *, force=True):
(4)             """
(4)             Select the backend used for rendering and GUI integration.
(4)             If pyplot is already imported, `~matplotlib.pyplot.switch_backend` is used
(4)             and if the new backend is different than the current backend, all Figures
(4)             will be closed.
(4)             Parameters
(4)             ----------
(4)             backend : str
(8)                 The backend to switch to.  This can either be one of the standard
(8)                 backend names, which are case-insensitive:
(8)                 - interactive backends:
(10)                  GTK3Agg, GTK3Cairo, GTK4Agg, GTK4Cairo, MacOSX, nbAgg, notebook, QtAgg,
(10)                  QtCairo, TkAgg, TkCairo, WebAgg, WX, WXAgg, WXCairo, Qt5Agg, Qt5Cairo
(8)                 - non-interactive backends:
```

```
(10)                    agg, cairo, pdf, pgf, ps, svg, template
(8)                 or a string of the form: ``module://my.module.name``.
(8)                 notebook is a synonym for nbAgg.
(8)                 Switching to an interactive backend is not possible if an unrelated
(8)                 event loop has already been started (e.g., switching to GTK3Agg if a
(8)                 TkAgg window has already been opened).  Switching to a non-interactive
(8)                 backend is always possible.
(4)             force : bool, default: True
(8)                 If True (the default), raise an `ImportError` if the backend cannot be
(8)                 set up (either because it fails to import, or because an incompatible
(8)                 GUI interactive framework is already running); if False, silently
(8)                 ignore the failure.

53: (4)                 Return custom data dictionary of (r, g, b) conversion functions, which can
54: (4)                 be used with `.ColormapRegistry.register`, for the cubehelix color scheme.
55: (4)                 Unlike most other color schemes cubehelix was designed by D.A. Green to
56: (4)                 be monotonically increasing in terms of perceived brightness.
57: (4)                 Also, when printed on a black and white postscript printer, the scheme
58: (4)                 results in a greyscale with monotonically increasing brightness.
59: (4)                 This color scheme is named cubehelix because the (r, g, b) values produced
60: (4)                 can be visualised as a squashed helix around the diagonal in the
61: (4)                 (r, g, b) color cube.
62: (4)                 For a unit color cube (i.e. 3D coordinates for (r, g, b) each in the
63: (4)                 range 0 to 1) the color scheme starts at (r, g, b) = (0, 0, 0), i.e.
black,
64: (4)                 and finishes at (r, g, b) = (1, 1, 1), i.e. white. For some fraction *x*,
65: (4)                 between 0 and 1, the color is the corresponding grey value at that
66: (4)                 fraction along the black to white diagonal (x, x, x) plus a color
67: (4)                 element. This color element is calculated in a plane of constant
68: (4)                 perceived intensity and controlled by the following parameters.
69: (4)                 Parameters
70: (4)                 ----------
71: (4)                 gamma : float, default: 1
72: (8)                     Gamma factor emphasizing either low intensity values (gamma < 1), or
73: (8)                     high intensity values (gamma > 1).
74: (4)                 s : float, default: 0.5 (purple)
75: (8)                     The starting color.
76: (4)                 r : float, default: -1.5
77: (8)                     The number of r, g, b rotations in color that are made from the start
78: (8)                     to the end of the color scheme.  The default of -1.5 corresponds to ->
79: (8)                     B -> G -> R -> B.
80: (4)                 h : float, default: 1
81: (8)                     The hue, i.e. how saturated the colors are. If this parameter is zero
82: (8)                     then the color scheme is purely a greyscale.

----------------------------------------

File 8 - _constrained_layout.py:

1: (0)              """
2: (0)              Adjust subplot layouts so that there are no overlapping Axes or Axes
3: (0)              decorations.  All Axes decorations are dealt with (labels, ticks, titles,
4: (0)              ticklabels) and some dependent artists are also dealt with (colorbar,
5: (0)              suptitle).
6: (0)              Layout is done via `~matplotlib.gridspec`, with one constraint per gridspec,
7: (0)              so it is possible to have overlapping Axes if the gridspecs overlap (i.e.
8: (0)              using `~matplotlib.gridspec.GridSpecFromSubplotSpec`).  Axes placed using
9: (0)              ``figure.subplots()`` or ``figure.add_subplots()`` will participate in the
10: (0)             layout.  Axes manually placed via ``figure.add_axes()`` will not.
11: (0)             See Tutorial: :ref:`constrainedlayout_guide`
12: (0)             General idea:
13: (0)             -------------
14: (0)             First, a figure has a gridspec that divides the figure into nrows and ncols,
15: (0)             with heights and widths set by ``height_ratios`` and ``width_ratios``,
16: (0)             often just set to 1 for an equal grid.
17: (0)             Subplotspecs that are derived from this gridspec can contain either a
18: (0)             ``SubPanel``, a ``GridSpecFromSubplotSpec``, or an ``Axes``.  The ``SubPanel``
19: (0)             and ``GridSpecFromSubplotSpec`` are dealt with recursively and each contain an
20: (0)             analogous layout.
21: (0)             Each ``GridSpec`` has a ``_layoutgrid`` attached to it.  The ``_layoutgrid``
22: (0)             has the same logical layout as the ``GridSpec``.   Each row of the grid spec
23: (0)             has a top and bottom "margin" and each column has a left and right "margin".
24: (0)             The "inner" height of each row is constrained to be the same (or as modified
25: (0)             by ``height_ratio``), and the "inner" width of each column is
26: (0)             constrained to be the same (as modified by ``width_ratio``), where "inner"
27: (0)             is the width or height of each column/row minus the size of the margins.
28: (0)             Then the size of the margins for each row and column are determined as the
29: (0)             max width of the decorators on each Axes that has decorators in that margin.
```

```
 30: (0)             For instance, a normal Axes would have a left margin that includes the
 31: (0)             left ticklabels, and the ylabel if it exists.  The right margin may include a
 32: (0)             colorbar, the bottom margin the xaxis decorations, and the top margin the
 33: (0)             title.
 34: (0)             With these constraints, the solver then finds appropriate bounds for the
 35: (0)             columns and rows.  It's possible that the margins take up the whole figure,
 36: (0)             in which case the algorithm is not applied and a warning is raised.
 37: (0)             See the tutorial :ref:`constrainedlayout_guide`
 38: (0)             for more discussion of the algorithm with examples.

374: (4)                """
```

```
(4)                 Make the margins that are submerged inside an Axes the same size.
(4)                 This allows Axes that span two columns (or rows) that are offset
(4)                 from one another to have the same size.
(4)                 This gives the proper layout for something like::
(8)                     fig = plt.figure(constrained_layout=True)
(8)                     axs = fig.subplot_mosaic("AAAB\nCCDD")
(4)                 Without this routine, the Axes D will be wider than C, because the
(4)                 margin width between the two columns in C has no width by default,
(4)                 whereas the margins between the two columns of D are set by the
(4)                 width of the margin between A and B. However, obviously the user would
(4)                 like C and D to be the same size, so we need to add constraints to these
(4)                 "submerged" margins.
(4)                 This routine makes all the interior margins the same, and the spacing
(4)                 between the three columns in A and the two column in C are all set to the
(4)                 margins between the two columns of D.
(4)                 See test_constrained_layout::test_constrained_layout12 for an example.

19: (4)                 """
20: (4)                 Define how the connection between two line segments is drawn.
21: (4)                 For a visual impression of each *JoinStyle*, `view these docs online
22: (4)                 <JoinStyle>`, or run `JoinStyle.demo`.
23: (4)                 Lines in Matplotlib are typically defined by a 1D `~.path.Path` and a
24: (4)                 finite ``linewidth``, where the underlying 1D `~.path.Path` represents the
25: (4)                 center of the stroked line.
26: (4)                 By default, `~.backend_bases.GraphicsContextBase` defines the boundaries
of
27: (4)                 a stroked line to simply be every point within some radius,
28: (4)                 ``linewidth/2``, away from any point of the center line. However, this
29: (4)                 results in corners appearing "rounded", which may not be the desired
30: (4)                 behavior if you are drawing, for example, a polygon or pointed star.
31: (4)                 **Supported values:**
32: (4)                 .. rst-class:: value-list
33: (8)                     'miter'
34: (12)                        the "arrow-tip" style. Each boundary of the filled-in area will
35: (12)                        extend in a straight line parallel to the tangent vector of the
36: (12)                        centerline at the point it meets the corner, until they meet in a
37: (12)                        sharp point.
38: (8)                     'round'
39: (12)                        stokes every point within a radius of ``linewidth/2`` of the
center
40: (12)                        lines.
41: (8)                     'bevel'
42: (12)                        the "squared-off" style. It can be thought of as a rounded corner
43: (12)                        where the "circular" part of the corner has been cut off.
44: (4)                 .. note::
45: (8)                     Very long miter tips are cut off (to form a *bevel*) after a
46: (8)                     backend-dependent limit called the "miter limit", which specifies the
47: (8)                     maximum allowed ratio of miter length to line width. For example, the
48: (8)                     PDF backend uses the default value of 10 specified by the PDF
standard,
49: (8)                     while the SVG backend does not even specify the miter limit, resulting
50: (8)                     in a default value of 4 per the SVG specification. Matplotlib does not
51: (8)                     currently allow the user to adjust this parameter.
52: (8)                     A more detailed description of the effect of a miter limit can be
found
53: (8)                     in the `Mozilla Developer Docs
54: (8)                     <https://developer.mozilla.org/en-US/docs/Web/SVG/Attribute/stroke-
miterlimit>`_

(0)  """
(0)  A class representing a Type 1 font.
(0)  This version reads pfa and pfb files and splits them for embedding in
(0)  pdf files. It also supports SlantFont and ExtendFont transformations,
(0)  similarly to pdfTeX and friends. There is no support yet for subsetting.
(0)  Usage::
(4)      font = Type1Font(filename)
(4)      clear_part, encrypted_part, finale = font.parts
(4)      slanted_font = font.transform({'slant': 0.167})
(4)      extended_font = font.transform({'extend': 1.2})

662: (8)                    Save the animation as a movie file by drawing every frame.
663: (8)                    Parameters
664: (8)                    ----------
665: (8)                    filename : str
666: (12)                       The output filename, e.g., :file:`mymovie.mp4`.
667: (8)                    writer : `MovieWriter` or str, default: :rc:`animation.writer`
668: (12)                       A `MovieWriter` instance to use or a key that identifies a
669: (12)                       class to use, such as 'ffmpeg'.
670: (8)                    fps : int, optional
671: (12)                       Movie frame rate (per second).  If not set, the frame rate from
the
672: (12)                       animation's frame interval.
673: (8)                    dpi : float, default: :rc:`savefig.dpi`
674: (12)                       Controls the dots per inch for the movie frames.  Together with
675: (12)                       the figure's size in inches, this controls the size of the movie.
676: (8)                    codec : str, default: :rc:`animation.codec`.
677: (12)                       The video codec to use.  Not all codecs are supported by a given
678: (12)                       `MovieWriter`.
679: (8)                    bitrate : int, default: :rc:`animation.bitrate`
680: (12)                       The bitrate of the movie, in kilobits per second.  Higher values
681: (12)                       means higher quality movies, but increase the file size.  A value
682: (12)                       of -1 lets the underlying movie encoder select the bitrate.
683: (8)                    extra_args : list of str or None, optional
684: (12)                       Extra command-line arguments passed to the underlying movie
encoder. These
685: (12)                       arguments are passed last to the encoder, just before the output
filename.
686: (12)                       The default, None, means to use :rc:`animation.[name-of-
encoder]_args` for
687: (12)                       the builtin writers.
688: (8)                    metadata : dict[str, str], default: {}
689: (12)                       Dictionary of keys and values for metadata to include in
```

```
690: (12)                        the output file. Some keys that may be of use include:
691: (12)                        title, artist, genre, subject, copyright, srcform, comment.
692: (8)                    extra_anim : list, default: []
693: (12)                        Additional `Animation` objects that should be included
694: (12)                        in the saved movie file. These need to be from the same
695: (12)                        `.Figure` instance. Also, animation frames will
696: (12)                        just be simply combined, so there should be a 1:1 correspondence
697: (12)                        between the frames from the different animations.
698: (8)                    savefig_kwargs : dict, default: {}
699: (12)                        Keyword arguments passed to each `~.Figure.savefig` call used to
700: (12)                        save the individual frames.
701: (8)                    progress_callback : function, optional
702: (12)                        A callback function that will be called for every frame to notify
703: (12)                        the saving progress. It must have the signature ::
704: (16)                            def func(current_frame: int, total_frames: int) -> Any
705: (12)                        where *current_frame* is the current frame number and
*total_frames* is the
706: (12)                        total number of frames to be saved. *total_frames* is set to None,
if the
707: (12)                        total number of frames cannot be determined. Return values may
exist but are
708: (12)                        ignored.
709: (12)                        Example code to write the progress to stdout::
710: (16)                            progress_callback = lambda i, n: print(f'Saving frame
{i}/{n}')
711: (8)                    Notes
712: (8)                    -----
713: (8)                    *fps*, *codec*, *bitrate*, *extra_args* and *metadata* are used to
714: (8)                    construct a `.MovieWriter` instance and can only be passed if
715: (8)                    *writer* is a string.  If they are passed as non-*None* and *writer*
716: (8)                    is a `.MovieWriter`, a `RuntimeError` will be raised.

(4)                 `TimedAnimation` subclass that makes an animation by repeatedly calling
(4)                 a function *func*.
(4)                 .. note::
(8)                     You must store the created Animation in a variable that lives as long
(8)                     as the animation should run. Otherwise, the Animation object will be
(8)                     garbage-collected and the animation stops.
(4)                 Parameters
(4)                 ----------
(4)                 fig : `~matplotlib.figure.Figure`
(8)                     The figure object used to get needed events, such as draw or resize.
(4)                 func : callable
(8)                     The function to call at each frame.  The first argument will
(8)                     be the next value in *frames*.   Any additional positional
(8)                     arguments can be supplied using `functools.partial` or via the *fargs*
(8)                     parameter.
(8)                     The required signature is::
```

```
            def func(frame, *fargs) -> iterable_of_artists
        It is often more convenient to provide the arguments using
        `functools.partial`. In this way it is also possible to pass keyword
        arguments. To pass a function with both positional and keyword
        arguments, set all arguments as keyword arguments, just leaving the
        *frame* argument unset::
            def func(frame, art, *, y=None):
                ...
            ani = FuncAnimation(fig, partial(func, art=ln, y='foo'))
        If ``blit == True``, *func* must return an iterable of all artists
        that were modified or created. This information is used by the blitting

        algorithm to determine which parts of the figure have to be updated.
        The return value is unused if ``blit == False`` and may be omitted in
        that case.
    frames : iterable, int, generator function, or None, optional
        Source of data to pass *func* and each frame of the animation
        - If an iterable, then simply use the values provided.  If the
          iterable has a length, it will override the *save_count* kwarg.
        - If an integer, then equivalent to passing ``range(frames)``
        - If a generator function, then must have the signature::
              def gen_function() -> obj
        - If *None*, then equivalent to passing ``itertools.count``.
        In all of these cases, the values in *frames* is simply passed through
        to the user-supplied *func* and thus can be of any type.
    init_func : callable, optional
        A function used to draw a clear frame. If not given, the results of
        drawing from the first item in the frames sequence will be used. This
        function will be called once before the first frame.
        The required signature is::
            def init_func() -> iterable_of_artists
        If ``blit == True``, *init_func* must return an iterable of artists
        to be re-drawn. This information is used by the blitting algorithm to
        determine which parts of the figure have to be updated.  The return
        value is unused if ``blit == False`` and may be omitted in that case.
    fargs : tuple or None, optional
        Additional arguments to pass to each call to *func*. Note: the use of
        `functools.partial` is preferred over *fargs*. See *func* for details.
    save_count : int, optional
        Fallback for the number of values from *frames* to cache. This is
        only used if the number of frames cannot be inferred from *frames*,
        i.e. when it's an iterator without length or a generator.
    interval : int, default: 200
        Delay between frames in milliseconds.
    repeat_delay : int, default: 0
        The delay in milliseconds between consecutive animation runs, if
        *repeat* is True.
    repeat : bool, default: True
        Whether the animation repeats when the sequence of frames is completed.
    blit : bool, default: False
        Whether blitting is used to optimize drawing.  Note: when using
        blitting, any animated artists will be drawn according to their zorder;

        however, they will be drawn on top of any previous artists, regardless
        of their zorder.
    cache_frame_data : bool, default: True
        Whether frame data is cached.  Disabling cache might be helpful when
        frames contain large objects.
    """

(8)                     Define the picking behavior of the artist.
(8)                     Parameters
(8)                     ----------
(8)                     picker : None or bool or float or callable
(12)                        This can be one of the following:
(12)                        - *None*: Picking is disabled for this artist (default).
(12)                        - A boolean: If *True* then picking will be enabled and the
(14)                          artist will fire a pick event if the mouse event is over
(14)                          the artist.
(12)                        - A float: If picker is a number it is interpreted as an
(14)                          epsilon tolerance in points and the artist will fire
(14)                          off an event if its data is within epsilon of the mouse
(14)                          event.  For some artists like lines and patch collections,
(14)                          the artist may provide additional data to the pick event
(14)                          that is generated, e.g., the indices of the data within
(14)                          epsilon of the pick event
(12)                        - A function: If picker is callable, it is a user supplied
(14)                          function which determines whether the artist is hit by the
(14)                          mouse event::
```

```
(16)                            hit, props = picker(artist, mouseevent)
(14)                          to determine the hit test.  if the mouse event is over the
(14)                          artist, return *hit=True* and props is a dictionary of
(14)                          properties you want added to the PickEvent attributes.

(8)                     """
(8)                     Set the snapping behavior.
(8)                     Snapping aligns positions with the pixel grid, which results in
(8)                     clearer images. For example, if a black line of 1px width was
(8)                     defined at a position in between two pixels, the resulting image
(8)                     would contain the interpolated value of that line in the pixel grid,
(8)                     which would be a grey value on both adjacent pixel positions. In
(8)                     contrast, snapping will move the line to the nearest integer pixel
(8)                     value, so that the resulting image will really contain a 1px wide
(8)                     black line.
(8)                     Snapping is currently only supported by the Agg and MacOSX backends.
(8)                     Parameters
(8)                     ----------
(8)                     snap : bool or None
(12)                        Possible values:
(12)                        - *True*: Snap vertices to the nearest pixel center.
(12)                        - *False*: Do not modify vertex positions.
(12)                        - *None*: (auto) If the path contains only rectilinear line
(14)                          segments, round to the nearest pixel center.
(8)                     """

(12)                    self.stale = True
(4)             @property
(4)             def sticky_edges(self):
(8)                 """
(8)                 ``x`` and ``y`` sticky edge lists for autoscaling.
(8)                 When performing autoscaling, if a data limit coincides with a value in
(8)                 the corresponding sticky_edges list, then no margin will be added--the
(8)                 view limit "sticks" to the edge. A typical use case is histograms,
(8)                 where one usually expects no margin on the bottom edge (0) of the
(8)                 histogram.
(8)                 Moreover, margin expansion "bumps" against sticky edges and cannot
(8)                 cross them.  For example, if the upper data limit is 1.0, the upper
(8)                 view limit computed by simple margin application is 1.2, but there is
a
(8)                 sticky edge at 1.1, then the actual upper view limit will be 1.1.
(8)                 This attribute cannot be assigned to; however, the ``x`` and ``y``
(8)                 lists can be modified in place as needed.
(8)                 Examples
(8)                 --------
(8)                 >>> artist.sticky_edges.x[:] = (xmin, xmax)
(8)                 >>> artist.sticky_edges.y[:] = (ymin, ymax)

(8)                   return artists
(4)               def get_cursor_data(self, event):
(8)                   """
(8)                   Return the cursor data for a given event.
(8)                   .. note::
(12)                      This method is intended to be overridden by artist subclasses.
(12)                      As an end-user of Matplotlib you will most likely not call this
(12)                      method yourself.
(8)                   Cursor data can be used by Artists to provide additional context
(8)                   information for a given event. The default implementation just returns
(8)                   *None*.
(8)                   Subclasses can override the method and return arbitrary data. However,
(8)                   when doing so, they must ensure that `.format_cursor_data` can convert
(8)                   the data to a string representation.
(8)                   The only current use case is displaying the z-value of an `.AxesImage`
(8)                   in the status bar of a plot window, while moving the mouse.
(8)                   Parameters
(8)                   ----------
(8)                   event : `~matplotlib.backend_bases.MouseEvent`
(8)                   See Also

(8)                     return
(4)                 return getattr(obj, 'get_' + property)()
(0)             get = getp
(0)             def setp(obj, *args, file=None, **kwargs):
```

```
(4)                 """
(4)                 Set one or more properties on an `.Artist`, or list allowed values.
(4)                 Parameters
(4)                 ----------
(4)                 obj : `~matplotlib.artist.Artist` or list of `.Artist`
(8)                     The artist(s) whose properties are being set or queried.  When setting
(8)                     properties, all artists are affected; when querying the allowed values,
(8)                     only the first instance in the sequence is queried.
(8)                     For example, two lines can be made thicker and red with a single call:
(8)                     >>> x = arange(0, 1, 0.01)
(8)                     >>> lines = plot(x, sin(2*pi*x), x, sin(4*pi*x))
(8)                     >>> setp(lines, linewidth=2, color='r')
(4)                 file : file-like, default: `sys.stdout`
(8)                     Where `setp` writes its output when asked to list allowed values.
(8)                     >>> with open('output.log') as file:
(8)                     ...     setp(line, file=file)
(8)                     The default, ``None``, means `sys.stdout`.
(4)                 *args, **kwargs
(8)                     The properties to set.  The following combinations are supported:
(8)                     - Set the linestyle of a line to be dashed:
(10)                      >>> line, = plot([1, 2, 3])
(10)                      >>> setp(line, linestyle='--')
(8)                     - Set multiple properties at once:
(10)                      >>> setp(line, linewidth=2, color='r')
(8)                     - List allowed values for a line's linestyle:
(10)                      >>> setp(line, 'linestyle')
(10)                      linestyle: {'-', '--', '-.', ':', '', (offset, on-off-seq), ...}
(8)                     - List all properties that can be set, and their allowed values:
(10)                      >>> setp(line)
(10)                      agg_filter: a filter function, ...
(10)                      [long output listing omitted]
(8)                     `setp` also supports MATLAB style string/value pairs.  For example, the
(8)                     following are equivalent:
(8)                     >>> setp(lines, 'linewidth', 2, 'color', 'r')  # MATLAB style
(8)                     >>> setp(lines, linewidth=2, color='r')        # Python style
(4)                 See Also

(4)             isDefault_label : bool
(4)             axes : `~matplotlib.axes.Axes`
```

```
            The `~.axes.Axes` to which the Axis belongs.
        major : `~matplotlib.axis.Ticker`
            Determines the major tick positions and their label format.
        minor : `~matplotlib.axis.Ticker`
            Determines the minor tick positions and their label format.
        callbacks : `~matplotlib.cbook.CallbackRegistry`
        label : `~matplotlib.text.Text`
            The axis label.
        labelpad : float
            The distance between the axis label and the tick labels.
            Defaults to :rc:`axes.labelpad` = 4.
        offsetText : `~matplotlib.text.Text`
            A `.Text` object containing the data offset of the ticks (if any).
        pickradius : float
            The acceptance radius for containment tests. See also
`.Axis.contains`.
        majorTicks : list of `.Tick`
            The major ticks.
            .. warning::
                Ticks are not guaranteed to be persistent. Various operations
                can create, delete and modify the Tick instances. There is an
                imminent risk that changes to individual ticks will not
                survive if you work on the figure further (including also
                panning/zooming on a displayed figure).
                Working on the individual ticks is a method of last resort.
                Use `.set_tick_params` instead if possible.
        minorTicks : list of `.Tick`
            The minor ticks.

(8)         r"""
(8)         [*Discouraged*] Set this Axis' tick labels with list of string labels.
(8)         .. admonition:: Discouraged
(12)            The use of this method is discouraged, because of the dependency
on
(12)            tick positions. In most cases, you'll want to use
(12)            ``Axes.set_[x/y/z]ticks(positions, labels)`` or ``Axis.set_ticks``
(12)            instead.
(12)            If you are using this method, you should always fix the tick
(12)            positions before, e.g. by using `.Axis.set_ticks` or by explicitly
(12)            setting a `~.ticker.FixedLocator`. Otherwise, ticks are free to
(12)            move and the labels may end up in unexpected positions.
(8)         Parameters
(8)         ----------
(8)         labels : sequence of str or of `.Text`\s
(12)            Texts for labeling each tick location in the sequence set by
(12)            `.Axis.set_ticks`; the number of labels must match the number of
locations.
(12)            The labels are used as is, via a `.FixedFormatter` (without
further
(12)            formatting).
(8)         minor : bool
(12)            If True, set minor ticks instead of major ticks.
(8)         fontdict : dict, optional
(12)            .. admonition:: Discouraged
(15)               The use of *fontdict* is discouraged. Parameters should be
passed as
(15)               individual keyword arguments or using dictionary-unpacking
(15)               ``set_ticklabels(..., **fontdict)``.
(12)            A dictionary controlling the appearance of the ticklabels.
(12)            The default *fontdict* is::
(15)               {'fontsize': rcParams['axes.titlesize'],
(16)                'fontweight': rcParams['axes.titleweight'],
(16)                'verticalalignment': 'baseline',
(16)                'horizontalalignment': loc}
(8)         **kwargs
```

```
(12)                        Text properties.
(12)                        .. warning::
(16)                            This only sets the properties of the current ticks, which is
(16)                            only sufficient for static plots.
(16)                            Ticks are not guaranteed to be persistent. Various operations
(16)                            can create, delete and modify the Tick instances. There is an
(16)                            imminent risk that these settings can get lost if you work on
(16)                            the figure further (including also panning/zooming on a
(16)                            displayed figure).
(16)                            Use `.set_tick_params` instead if possible.
(8)                     Returns
(8)                     -------
(8)                     list of `.Text`\s
(12)                        For each tick, includes ``tick.label1`` if it is visible, then
(12)                        ``tick.label2`` if it is visible, in that order.

(8)                 """
(8)                 Set this Axis' tick locations and optionally tick labels.
(8)                 If necessary, the view limits of the Axis are expanded so that all
(8)                 given ticks are visible.
(8)                 Parameters
(8)                 ----------
(8)                 ticks : 1D array-like
(12)                    Array of tick locations (either floats or in axis units). The axis
(12)                    `.Locator` is replaced by a `~.ticker.FixedLocator`.
(12)                    Pass an empty list (``set_ticks([])``) to remove all ticks.
(12)                    Some tick formatters will not label arbitrary tick positions;
(12)                    e.g. log formatters only label decade ticks by default. In
(12)                    such a case you can set a formatter explicitly on the axis
(12)                    using `.Axis.set_major_formatter` or provide formatted
(12)                    *labels* yourself.
(8)                 labels : list of str, optional
(12)                    Tick labels for each location in *ticks*; must have the same
length as
(12)                    *ticks*. If set, the labels are used as is, via a
`.FixedFormatter`.
(12)                    If not set, the labels are generated using the axis tick
`.Formatter`.
(8)                 minor : bool, default: False
(12)                    If ``False``, set only the major ticks; if ``True``, only the
minor ticks.
(8)                 **kwargs
(12)                    `.Text` properties for the labels. Using these is only allowed if
(12)                    you pass *labels*. In other cases, please use
`~.Axes.tick_params`.
(8)                 Notes
(8)                 -----
(8)                 The mandatory expansion of the view limits is an intentional design
(8)                 choice to prevent the surprise of a non-visible tick. If you need
(8)                 other limits, you should set the limits explicitly after setting the
(8)                 ticks.

(0)             class TimerBase:
(4)                 """
(4)                 A base class for providing timer events, useful for things animations.
(4)                 Backends need to implement a few specific methods in order to use their
(4)                 own timing mechanisms so that the timer events are integrated into their
(4)                 event loops.
(4)                 Subclasses must override the following methods:
(4)                 - ``_timer_start``: Backend-specific code for starting the timer.
(4)                 - ``_timer_stop``: Backend-specific code for stopping the timer.
(4)                 Subclasses may additionally override the following methods:
(4)                 - ``_timer_set_single_shot``: Code for setting the timer to single shot
(6)                   operating mode, if supported by the timer object.  If not, the `Timer`
(6)                   class itself will store the flag and the ``_on_timer`` method should be
(6)                   overridden to support such behavior.
(4)                 - ``_timer_set_interval``: Code for setting the interval on the timer, if
(6)                   there is a method for doing so on the timer object.
(4)                 - ``_on_timer``: The internal function that any timer object should call,
(6)                   which will handle the task of running all callbacks that have been set.

(4)                 A mouse event ('button_press_event', 'button_release_event', \
(0)             'scroll_event', 'motion_notify_event').
(4)                 A MouseEvent has a number of special attributes in addition to those
(4)                 defined by the parent `Event` and `LocationEvent` classes.
(4)                 Attributes
(4)                 ----------
(4)                 button : None or `MouseButton` or {'up', 'down'}
(8)                     The button pressed. 'up' and 'down' are used for scroll events.
(8)                     Note that LEFT and RIGHT actually refer to the "primary" and
(8)                     "secondary" buttons, i.e. if the user inverts their left and right
(8)                     buttons ("left-handed setting") then the LEFT button will be the one
(8)                     physically on the right.
```

```
(8)                 If this is unset, *name* is "scroll_event", and *step* is nonzero, then
(8)                 this will be set to "up" or "down" depending on the sign of *step*.
(4)             key : None or str
(8)                 The key pressed when the mouse event triggered, e.g. 'shift'.
(8)                 See `KeyEvent`.
(8)                 .. warning::
(11)                   This key is currently obtained from the last 'key_press_event' or
(11)                   'key_release_event' that occurred within the canvas.  Thus, if the
(11)                   last change of keyboard state occurred while the canvas did not have
(11)                   focus, this attribute will be wrong.  On the other hand, the
(11)                   ``modifiers`` attribute should always be correct, but it can only
(11)                   report on modifier keys.
(4)             step : float
(8)                 The number of scroll steps (positive for 'up', negative for 'down').
(8)                 This applies only to 'scroll_event' and defaults to 0 otherwise.
(4)             dblclick : bool
(8)                 Whether the event is a double-click. This applies only to
(8)                 'button_press_event' and is False otherwise. In particular, it's
(8)                 not used in 'button_release_event'.
(4)             Examples
(4)             --------
(4)             ::
(8)                 def on_press(event):
(12)                    print('you pressed', event.button, event.xdata, event.ydata)
(8)                 cid = fig.canvas.mpl_connect('button_press_event', on_press)
(4)             """

(0)         class PickEvent(Event):
(4)             """
(4)             A pick event.
(4)             This event is fired when the user picks a location on the canvas
(4)             sufficiently close to an artist that has been made pickable with
(4)             `.Artist.set_picker`.
(4)             A PickEvent has a number of special attributes in addition to those defined
(4)             by the parent `Event` class.
(4)             Attributes
(4)             ----------
(4)             mouseevent : `MouseEvent`
(8)                 The mouse event that generated the pick.
(4)             artist : `~matplotlib.artist.Artist`
(8)                 The picked artist.  Note that artists are not pickable by default
(8)                 (see `.Artist.set_picker`).
(4)             other
(8)                 Additional attributes may be present depending on the type of the
(8)                 picked object; e.g., a `.Line2D` pick may define different extra
(8)                 attributes than a `.PatchCollection` pick.
```

```
(4)             Examples
(4)             --------

(4)             of the picked data point::
(8)                 ax.plot(np.rand(100), 'o', picker=5)  # 5 points tolerance
(8)                 def on_pick(event):
(12)                    line = event.artist
(12)                    xdata, ydata = line.get_data()
(12)                    ind = event.ind
(12)                    print(f'on pick line: {xdata[ind]:.3f}, {ydata[ind]:.3f}')
(8)                 cid = fig.canvas.mpl_connect('pick_event', on_pick)
(4)             """
(4)             def __init__(self, name, canvas, mouseevent, artist,
(17)                         guiEvent=None, **kwargs):
(8)                 if guiEvent is None:
(12)                    guiEvent = mouseevent.guiEvent
(8)                 super().__init__(name, canvas, guiEvent)
(8)                 self.mouseevent = mouseevent
(8)                 self.artist = artist
(8)                 self.__dict__.update(kwargs)
(0)         class KeyEvent(LocationEvent):
(4)             """
(4)             A key event (key press, key release).
(4)             A KeyEvent has a number of special attributes in addition to those defined
(4)             by the parent `Event` and `LocationEvent` classes.
(4)             Attributes
(4)             ----------
(4)             key : None or str
(8)                 The key(s) pressed. Could be *None*, a single case sensitive Unicode
(8)                 character ("g", "G", "#", etc.), a special key ("control", "shift",
(8)                 "f1", "up", etc.) or a combination of the above (e.g., "ctrl+alt+g",
(8)                 "ctrl+alt+G").
(4)             Notes
(4)             -----
(4)             Modifier keys will be prefixed to the pressed key and will be in the order
(4)             "ctrl", "alt", "super". The exception to this rule is when the pressed key
(4)             is itself a modifier key, therefore "ctrl+alt" and "alt+control" can both
(4)             be valid key values.
(4)             Examples
(4)             --------
(4)             ::
(8)                 def on_key(event):

1300: (0)            def _allow_interrupt(prepare_notifier, handle_sigint):
1301: (4)                """
1302: (4)                A context manager that allows terminating a plot by sending a SIGINT.  It
1303: (4)                is necessary because the running backend prevents the Python interpreter
1304: (4)                from running and processing signals (i.e., to raise a KeyboardInterrupt).
1305: (4)                To solve this, one needs to somehow wake up the interpreter and make it
1306: (4)                close the plot window.  We do this by using the signal.set_wakeup_fd()
1307: (4)                function which organizes a write of the signal number into a socketpair.
1308: (4)                A backend-specific function, *prepare_notifier*, arranges to listen to
1309: (4)                the pair's read socket while the event loop is running.  (If it returns a
1310: (4)                notifier object, that object is kept alive while the context manager
runs.)
1311: (4)                If SIGINT was indeed caught, after exiting the on_signal() function the
1312: (4)                interpreter reacts to the signal according to the handler function which
1313: (4)                had been set up by a signal.signal() call; here, we arrange to call the
1314: (4)                backend-specific *handle_sigint* function.  Finally, we call the old
SIGINT
1315: (4)                handler with the same arguments that were given to our custom handler.
1316: (4)                We do this only if the old handler for SIGINT was not None, which means
```

```
(4)                 that a non-python handler was installed, i.e. in Julia, and not SIG_IGN
(4)                 which means we should ignore the interrupts.
(4)                 Parameters
(4)                 ----------
(4)                 prepare_notifier : Callable[[socket.socket], object]
(4)                 handle_sigint : Callable[[], object]

    def mpl_connect(self, s, func):
        """
        Bind function *func* to event *s*.
        Parameters
        ----------
        s : str
            One of the following events ids:
            - 'button_press_event'
            - 'button_release_event'
            - 'draw_event'
            - 'key_press_event'
            - 'key_release_event'
            - 'motion_notify_event'
            - 'pick_event'
            - 'resize_event'
            - 'scroll_event'
            - 'figure_enter_event',
            - 'figure_leave_event',
            - 'axes_enter_event',
            - 'axes_leave_event'
            - 'close_event'.
        func : callable
            The callback function to be executed, which must have the
            signature::
                def func(event: Event) -> Any
            For the location events (button and key press/release), if the
            mouse is over the Axes, the ``inaxes`` attribute of the event will
            be set to the `~matplotlib.axes.Axes` the event occurs is over, and

            additionally, the variables ``xdata`` and ``ydata`` attributes will

            be set to the mouse location in data coordinates.  See `.KeyEvent`
            and `.MouseEvent` for more info.
            .. note::
                If func is a method, this only stores a weak reference to the
                method. Thus, the figure does not influence the lifetime of
                the associated object. Usually, you want to make sure that the
                object is kept alive throughout the lifetime of the figure by
                holding a reference to it.
        Returns
        -------
        cid
            A connection id that can be used with
            `.FigureCanvasBase.mpl_disconnect`.
        Examples
        --------
        ::
            def on_press(event):
                print('you pressed', event.button, event.xdata, event.ydata)
```

```

(4)         def new_timer(self, interval=None, callbacks=None):
(8)             """
(8)             Create a new backend-specific subclass of `.Timer`.
(8)             This is useful for getting periodic events through the backend's
native
(8)             event loop.  Implemented only for backends with GUIs.
(8)             Parameters
(8)             ----------
(8)             interval : int
(12)                Timer interval in milliseconds.
(8)             callbacks : list[tuple[callable, tuple, dict]]
(12)                Sequence of (func, args, kwargs) where ``func(*args, **kwargs)``
(12)                will be executed by the timer every *interval*.
(12)                Callbacks which return ``False`` or ``0`` will be removed from the
(12)                timer.
(8)             Examples
(8)             --------
(8)             >>> timer = fig.canvas.new_timer(callbacks=[(f1, (1,), {'a': 3})])
(8)             """
(8)             return self._timer_cls(interval=interval, callbacks=callbacks)
(4)         def flush_events(self):
(8)             """
(8)             Flush the GUI events for the figure.
(8)             Interactive backends need to reimplement this method.
(8)             """
(4)         def start_event_loop(self, timeout=0):
(8)             """
(8)             Start a blocking event loop.
(8)             Such an event loop is used by interactive functions, such as
(8)             `~.Figure.ginput` and `~.Figure.waitforbuttonpress`, to wait for
(8)             events.
(8)             The event loop blocks until a callback function triggers
(8)             `stop_event_loop`, or *timeout* is reached.
(8)             If *timeout* is 0 or negative, never timeout.
(8)             Only interactive backends need to reimplement this method and it
relies
(8)             on `flush_events` being properly implemented.
(8)             Interactive backends should implement this in a more native way.
(8)             """

2049: (4)               A backend-independent abstraction of a figure container and controller.
2050: (4)               The figure manager is used by pyplot to interact with the window in a
2051: (4)               backend-independent way. It's an adapter for the real (GUI) framework that
2052: (4)               represents the visual figure on screen.
2053: (4)               The figure manager is connected to a specific canvas instance, which in
turn
2054: (4)               is connected to a specific figure instance. To access a figure manager for
```

```
(4)                 a given figure in user code, you typically use ``fig.canvas.manager``.
(4)                 GUI backends derive from this class to translate common operations such
(4)                 as *show* or *resize* to the GUI-specific code. Non-GUI backends do not
(4)                 support these operations and can just use the base class.
(4)                 This following basic operations are accessible:
(4)                 **Window operations**
(4)                 - `~.FigureManagerBase.show`
(4)                 - `~.FigureManagerBase.destroy`
(4)                 - `~.FigureManagerBase.full_screen_toggle`
(4)                 - `~.FigureManagerBase.resize`
(4)                 - `~.FigureManagerBase.get_window_title`
(4)                 - `~.FigureManagerBase.set_window_title`
(4)                 **Key and mouse button press handling**
(4)                 The figure manager sets up default key and mouse button press handling by
(4)                 hooking up the `.key_press_handler` to the matplotlib event system. This
(4)                 ensures the same shortcuts and mouse actions across backends.
(4)                 **Other operations**
(4)                 Subclasses will have additional attributes and functions to access
(4)                 additional functionality. This is of course backend-specific. For example,
(4)                 most GUI backends have ``window`` and ``toolbar`` attributes that give
(4)                 access to the native GUI widgets of the respective framework.
(4)                 Attributes
(4)                 ----------
(4)                 canvas : `FigureCanvasBase`
(8)                     The backend-specific canvas instance.
(4)                 num : int or str
(8)                     The figure number.
(4)                 key_press_handler_id : int
(8)                     The default key handler cid, when using the toolmanager.
(8)                     To disable the default key press handling use::
(12)                        figure.canvas.mpl_disconnect(
(16)                            figure.canvas.manager.key_press_handler_id)
(4)                 button_press_handler_id : int
(8)                     The default mouse button handler cid, when using the toolmanager.

```

```
(8)                 >>> callbacks.process('drink', 123)
(8)                 drink 123
(4)             In practice, one should always disconnect all callbacks when they are
(4)             no longer needed to avoid dangling references (and thus memory leaks).
(4)             However, real code in Matplotlib rarely does so, and due to its design,
(4)             it is rather difficult to place this kind of code.  To get around this,
(4)             and prevent this class of memory leaks, we instead store weak references
(4)             to bound methods only, so when the destination object needs to die, the
(4)             CallbackRegistry won't keep it alive.
(4)             Parameters
(4)             ----------
(4)             exception_handler : callable, optional
(7)                If not None, *exception_handler* must be a function that takes an
(7)                `Exception` as single parameter.  It gets called with any `Exception`
(7)                raised by the callbacks during `CallbackRegistry.process`, and may
(7)                either re-raise the exception or handle it in another manner.
(7)                The default handler prints the exception (with `traceback.print_exc`)
if
(7)                an interactive event loop is running; it re-raises the exception if no
(7)                interactive event loop is running.
(4)             signals : list, optional
(8)                 If not None, *signals* is a list of signals that this registry
handles:
(8)                 attempting to `process` or to `connect` to a signal not in the list
(8)                 throws a `ValueError`.  The default, None, does not restrict the
(8)                 handled signals.
(4)             """

(8)                     ``Q1 - whis*(Q3-Q1)``, and the upper whisker at the highest datum
below
(8)                     ``Q3 + whis*(Q3-Q1)``, where Q1 and Q3 are the first and third
(8)                     quartiles.  The default value of ``whis = 1.5`` corresponds to Tukey's
(8)                     original definition of boxplots.
(8)                     If a pair of floats, they indicate the percentiles at which to draw
the
(8)                     whiskers (e.g., (5, 95)).  In particular, setting this to (0, 100)
(8)                     results in whiskers covering the whole range of the data.
(8)                     In the edge case where ``Q1 == Q3``, *whis* is automatically set to
(8)                     (0, 100) (cover the whole range of the data) if *autorange* is True.
(8)                     Beyond the whiskers, data are considered outliers and are plotted as
(8)                     individual points.
(4)                 bootstrap : int, optional
(8)                     Number of times the confidence intervals around the median
(8)                     should be bootstrapped (percentile method).
(4)                 labels : list of str, optional
(8)                     Labels for each dataset. Length must be compatible with
(8)                     dimensions of *X*.
(4)                 autorange : bool, optional (False)
(8)                     When `True` and the data are distributed such that the 25th and 75th
(8)                     percentiles are equal, ``whis`` is set to (0, 100) such that the
(8)                     whisker ends are at the minimum and maximum of the data.
(4)                 Returns
(4)                 -------
(4)                 list of dict
(8)                     A list of dictionaries containing the results for each column
(8)                     of data. Keys of each dictionary are the following:
(8)                     ========   ===================================
(8)                     Key        Value Description
(8)                     ========   ===================================
(8)                     label      tick label for the boxplot
(8)                     mean       arithmetic mean value
(8)                     med        50th percentile
(8)                     q1         first quartile (25th percentile)
(8)                     q3         third quartile (75th percentile)
(8)                     iqr        interquartile range
(8)                     cilo       lower notch around the median
(8)                     cihi       upper notch around the median
(8)                     whislo     end of the lower whisker
(8)                     whishi     end of the upper whisker
(8)                     fliers     outliers
(8)                     ========   ===================================
(4)                 Notes
(4)                 -----
(4)                 Non-bootstrapping approach to confidence interval uses Gaussian-based
(4)                 asymptotic approximation:
(4)                 .. math::
(8)                     \mathrm{med} \pm 1.57 \times \frac{\mathrm{iqr}}{\sqrt{N}}
(4)                 General approach from:

(4)             Return a list of dictionaries of data which can be used to draw a series
(4)             of violin plots.
(4)             See the ``Returns`` section below to view the required keys of the
(4)             dictionary.
(4)             Users can skip this function and pass a user-defined set of dictionaries
(4)             with the same keys to `~.axes.Axes.violinplot` instead of using Matplotlib
(4)             to do the calculations. See the *Returns* section below for the keys
(4)             that must be present in the dictionaries.
(4)             Parameters
(4)             ----------
(4)             X : array-like
(8)                 Sample data that will be used to produce the gaussian kernel density
(8)                 estimates. Must have 2 or fewer dimensions.
(4)             method : callable
(8)                 The method used to calculate the kernel density estimate for each
(8)                 column of data. When called via ``method(v, coords)``, it should
(8)                 return a vector of the values of the KDE evaluated at the values
(8)                 specified in coords.
(4)             points : int, default: 100
(8)                 Defines the number of points to evaluate each of the gaussian kernel
(8)                 density estimates at.
(4)             quantiles : array-like, default: None
(8)                 Defines (if not None) a list of floats in interval [0, 1] for each
(8)                 column of data, which represents the quantiles that will be rendered
(8)                 for that column of data. Must have 2 or fewer dimensions. 1D array
will
(8)                 be treated as a singleton list containing them.
(4)             Returns
(4)             -------
(4)             list of dict
(8)                 A list of dictionaries containing the results for each column of data.
(8)                 The dictionaries contain at least the following:
(8)                 - coords: A list of scalars containing the coordinates this particular
(10)                  kernel density estimate was evaluated at.
(8)                 - vals: A list of scalars containing the values of the kernel density
(10)                  estimate at each of the coordinates given in *coords*.
(8)                 - mean: The mean value for this column of data.
(8)                 - median: The median value for this column of data.
(8)                 - min: The minimum value for this column of data.
(8)                 - max: The maximum value for this column of data.
(8)                 - quantiles: The quantile values for this column of data.
(4)             """

(4)                 def to_rgba(self, x, alpha=None, bytes=False, norm=True):
(8)                     """
(8)                     Return a normalized RGBA array corresponding to *x*.
(8)                     In the normal case, *x* is a 1D or 2D sequence of scalars, and
(8)                     the corresponding `~numpy.ndarray` of RGBA values will be returned,
(8)                     based on the norm and colormap set for this ScalarMappable.
(8)                     There is one special case, for handling images that are already
(8)                     RGB or RGBA, such as might have been read from an image file.
(8)                     If *x* is an `~numpy.ndarray` with 3 dimensions,
(8)                     and the last dimension is either 3 or 4, then it will be
(8)                     treated as an RGB or RGBA array, and no mapping will be done.
(8)                     The array can be `~numpy.uint8`, or it can be floats with
(8)                     values in the 0-1 range; otherwise a ValueError will be raised.
(8)                     Any NaNs or masked elements will be set to 0 alpha.
(8)                     If the last dimension is 3, the *alpha* kwarg (defaulting to 1)
(8)                     will be used to fill in the transparency.  If the last dimension
(8)                     is 4, the *alpha* kwarg is ignored; it does not
(8)                     replace the preexisting alpha.  A ValueError will be raised
(8)                     if the third dimension is other than 3 or 4.
(8)                     In either case, if *bytes* is *False* (default), the RGBA
(8)                     array will be floats in the 0-1 range; if it is *True*,
(8)                     the returned RGBA array will be `~numpy.uint8` in the 0 to 255 range.
(8)                     If norm is False, no normalization of the input data is
(8)                     performed, and it is assumed to be in the range (0-1).
(8)                     """

26: (0)             })
27: (0)             class Collection(artist.Artist, cm.ScalarMappable):
28: (4)                 r"""
29: (4)                 Base class for Collections. Must be subclassed to be usable.
30: (4)                 A Collection represents a sequence of `.Patch`\es that can be drawn
31: (4)                 more efficiently together than individually. For example, when a single
32: (4)                 path is being drawn repeatedly at different offsets, the renderer can
33: (4)                 typically execute a ``draw_marker()`` call much more efficiently than a
34: (4)                 series of repeated calls to ``draw_path()`` with the offsets put in
35: (4)                 one-by-one.
36: (4)                 Most properties of a collection can be configured per-element. Therefore,
37: (4)                 Collections have "plural" versions of many of the properties of a `.Patch`
38: (4)                 (e.g. `.Collection.get_paths` instead of `.Patch.get_path`). Exceptions
are
39: (4)                 the *zorder*, *hatch*, *pickradius*, *capstyle* and *joinstyle*
properties,
40: (4)                 which can only be set globally for the whole collection.
41: (4)                 Besides these exceptions, all properties can be specified as single values
42: (4)                 (applying to all elements) or sequences of values. The property of the
43: (4)                 ``i``\th element of the collection is::
44: (6)                   prop[i % len(prop)]
45: (4)                 Each Collection can optionally be used as its own `.ScalarMappable` by
46: (4)                 passing the *norm* and *cmap* parameters to its constructor. If the
47: (4)                 Collection's `.ScalarMappable` matrix ``_A`` has been set (via a call
48: (4)                 to `.Collection.set_array`), then at draw time this internal scalar
49: (4)                 mappable will be used to set the ``facecolors`` and ``edgecolors``,
50: (4)                 ignoring those that were manually passed in.

74: (8)                     Parameters
75: (8)                     ----------
76: (8)                     edgecolors : :mpltype:`color` or list of colors, default:
:rc:`patch.edgecolor`
77: (12)                        Edge color for each patch making up the collection. The special
78: (12)                        value 'face' can be passed to make the edgecolor match the
79: (12)                        facecolor.
80: (8)                     facecolors : :mpltype:`color` or list of colors, default:
:rc:`patch.facecolor`
81: (12)                        Face color for each patch making up the collection.
82: (8)                     linewidths : float or list of floats, default: :rc:`patch.linewidth`
83: (12)                        Line width for each patch making up the collection.
84: (8)                     linestyles : str or tuple or list thereof, default: 'solid'
85: (12)                        Valid strings are ['solid', 'dashed', 'dashdot', 'dotted', '-',
86: (12)                        '--', '-.', ':']. Dash tuples should be of the form::
87: (16)                            (offset, onoffseq),
88: (12)                        where *onoffseq* is an even length tuple of on and off ink lengths
89: (12)                        in points. For examples, see
90: (12)                        :doc:`/gallery/lines_bars_and_markers/linestyles`.
91: (8)                     capstyle : `.CapStyle`-like, default: :rc:`patch.capstyle`
92: (12)                        Style to use for capping lines for all paths in the collection.
93: (12)                        Allowed values are %(CapStyle)s.
94: (8)                     joinstyle : `.JoinStyle`-like, default: :rc:`patch.joinstyle`
95: (12)                        Style to use for joining lines for all paths in the collection.
96: (12)                        Allowed values are %(JoinStyle)s.
97: (8)                     antialiaseds : bool or list of bool, default: :rc:`patch.antialiased`
98: (12)                        Whether each patch in the collection should be drawn with
99: (12)                        antialiasing.
100: (8)                    offsets : (float, float) or list thereof, default: (0, 0)
101: (12)                       A vector by which to translate each patch after rendering (default
102: (12)                       is no translation). The translation is performed in screen (pixel)
103: (12)                       coordinates (i.e. after the Artist's transform is applied).
104: (8)                    offset_transform : `~.Transform`, default: `.IdentityTransform`
105: (12)                       A single transform which will be applied to each *offsets* vector
106: (12)                       before it is used.
107: (8)                    cmap, norm
108: (12)                       Data normalization and colormapping parameters. See
109: (12)                       `.ScalarMappable` for a detailed description.
110: (8)                    hatch : str, optional
111: (12)                       Hatching pattern to use in filled paths, if any. Valid strings are
112: (12)                       ['/', '\\', '|', '-', '+', 'x', 'o', 'O', '.', '*']. See
113: (12)                       :doc:`/gallery/shapes_and_collections/hatch_style_reference` for
114: (12)                       the meaning of each hatch type.
115: (8)                    pickradius : float, default: 5.0
116: (12)                       If ``pickradius <= 0``, then `.Collection.contains` will return
117: (12)                       ``True`` whenever the test point is inside of one of the polygons
118: (12)                       formed by the control points of a Path in the Collection. On the
119: (12)                       other hand, if it is greater than 0, then we instead check if the
120: (12)                       test point is contained in a stroke of width ``2*pickradius``
121: (12)                       following any of the Paths in the Collection.
122: (8)                    urls : list of str, default: None
123: (12)                       A URL for each patch to link to once drawn. Currently only works
124: (12)                       for the SVG backend. See :doc:`/gallery/misc/hyperlinks_sgskip`
for
125: (12)                       examples.
126: (8)                    zorder : float, default: 1
127: (12)                       The drawing order, shared by all Patches in the Collection. See
128: (12)                       :doc:`/gallery/misc/zorder_demo` for all defaults and examples.
129: (8)                    **kwargs
130: (12)                       Remaining keyword arguments will be used to set properties as
```

```
131: (12)                        ``Collection.set_{key}(val)`` for each key-value pair in *kwargs*.

    A collection of `~.path.Path`\s, as created by e.g. `~.Axes.scatter`.
    """
    def __init__(self, paths, sizes=None, **kwargs):
        """
        Parameters
        ----------
        paths : list of `.path.Path`
            The paths that will make up the `.Collection`.
        sizes : array-like
            The factor by which to scale each drawn `~.path.Path`. One unit
            squared in the Path's data space is scaled to be ``sizes**2``
            points when rendered.
        **kwargs
            Forwarded to `.Collection`.
        """
        super().__init__(**kwargs)

    def get_paths(self):
        return self._paths
    def legend_elements(self, prop="colors", num="auto",
                        fmt=None, func=lambda x: x, **kwargs):
        """
        Create legend handles and labels for a PathCollection.
        Each legend handle is a `.Line2D` representing the Path that was drawn,
        and each label is a string that represents the Path.
        This is useful for obtaining a legend for a `~.Axes.scatter` plot;
        e.g.::
            scatter = plt.scatter([1, 2, 3],  [4, 5, 6],  c=[7, 2, 3], num=None)
            plt.legend(*scatter.legend_elements())
        creates three legend elements, one for each color with the numerical
        values passed to *c* as the labels.
        Also see the :ref:`automatedlegendcreation` example.
        Parameters
        ----------
        prop : {"colors", "sizes"}, default: "colors"
            If "colors", the legend handles will show the different colors of
            the collection. If "sizes", the legend will show the different
```

```
(12)                        sizes. To set both, use *kwargs* to directly edit the `.Line2D`
(12)                        properties.
(8)                     num : int, None, "auto" (default), array-like, or `~.ticker.Locator`
(12)                        Target number of elements to create.
(12)                        If None, use all unique elements of the mappable array. If an
(12)                        integer, target to use *num* elements in the normed range.
(12)                        If *"auto"*, try to determine which option better suits the nature
(12)                        of the data.
(12)                        The number of created elements may slightly deviate from *num* due
(12)                        to a `~.ticker.Locator` being used to find useful locations.
(12)                        If a list or array, use exactly those elements for the legend.
(12)                        Finally, a `~.ticker.Locator` can be provided.
(8)                     fmt : str, `~matplotlib.ticker.Formatter`, or None (default)
(12)                        The format or formatter to use for the labels. If a string must be
(12)                        a valid input for a `.StrMethodFormatter`. If None (the default),
(12)                        use a `.ScalarFormatter`.
(8)                     func : function, default: ``lambda x: x``
(12)                        Function to calculate the labels.  Often the size (or color)
(12)                        argument to `~.Axes.scatter` will have been pre-processed by the
(12)                        user using a function ``s = f(x)`` to make the markers visible;
(12)                        e.g. ``size = np.log10(x)``.  Providing the inverse of this
(12)                        function here allows that pre-processing to be inverted, so that
(12)                        the legend labels have the correct values; e.g. ``func = lambda
(12)                        x: 10**x``.
(8)                     **kwargs
(12)                        Allowed keyword arguments are *color* and *size*. E.g. it may be
(12)                        useful to set the color of the markers if *prop="sizes"* is used;
(12)                        similarly to set the size of the markers if *prop="colors"* is
(12)                        used. Any further parameters are passed onto the `.Line2D`
(12)                        instance. This may be useful to e.g. specify a different
(12)                        *markeredgecolor* or *alpha* for the legend handles.
(8)                     Returns
(8)                     -------
(8)                     handles : list of `.Line2D`
(12)                        Visual representation of each element of the legend.
(8)                     labels : list of str
(12)                        The string labels for elements of the legend.
(8)                     """

        Set the data values.
        Parameters
        ----------
        A : array-like
            The mesh data. Supported array shapes are:
            - (M, N) or (M*N,): a mesh with scalar data. The values are mapped
              to colors using normalization and a colormap. See parameters
              *norm*, *cmap*, *vmin*, *vmax*.
            - (M, N, 3): an image with RGB values (0-1 float or 0-255 int).
            - (M, N, 4): an image with RGBA values (0-1 float or 0-255 int),
              i.e. including transparency.
            If the values are provided as a 2D grid, the shape must match the
            coordinates grid. If the values are 1D, they are reshaped to 2D.
            M, N follow from the coordinates grid, where the coordinates grid
            shape is (M, N) for 'gouraud' *shading* and (M+1, N+1) for 'flat'
            shading.

(4)             Notes
(4)             -----
(4)             Unlike `.QuadMesh`, this class will draw each cell as an individual
Polygon.
(4)             This is significantly slower, but allows for more flexibility when wanting
(4)             to add additional properties to the cells, such as hatching.
(4)             Another difference from `.QuadMesh` is that if any of the vertices or data
(4)             of a cell are masked, that Polygon will **not** be drawn and it won't be
in
(4)             the list of paths returned.
(4)             """

(0)         @_docstring.interpd
(0)         class Colorbar:
(4)             r"""
(4)             Draw a colorbar in an existing Axes.
(4)             Typically, colorbars are created using `.Figure.colorbar` or
(4)             `.pyplot.colorbar` and associated with `.ScalarMappable`\s (such as an
(4)             `.AxesImage` generated via `~.axes.Axes.imshow`).
(4)             In order to draw a colorbar not associated with other elements in the
(4)             figure, e.g. when showing a colormap by itself, one can create an empty
(4)             `.ScalarMappable`, or directly pass *cmap* and *norm* instead of
*mappable*
(4)             to `Colorbar`.
(4)             Useful public methods are :meth:`set_label` and :meth:`add_lines`.
(4)             Attributes
(4)             ----------
(4)             ax : `~matplotlib.axes.Axes`
(8)                 The `~.axes.Axes` instance in which the colorbar is drawn.
(4)             lines : list
(8)                 A list of `.LineCollection` (empty if no lines were drawn).
(4)             dividers : `.LineCollection`
(8)                 A LineCollection (empty if *drawedges* is ``False``).
(4)             Parameters
(4)             ----------
(4)             ax : `~matplotlib.axes.Axes`
(8)                 The `~.axes.Axes` instance in which the colorbar is drawn.
(4)             mappable : `.ScalarMappable`
(8)                 The mappable whose colormap and norm will be used.
(8)                 To show the under- and over- value colors, the mappable's norm should
(8)                 be specified as ::
(12)                    norm = colors.Normalize(clip=False)
(8)                 To show the colors versus index instead of on a 0-1 scale, use::
(12)                    norm=colors.NoNorm()
(4)             cmap : `~matplotlib.colors.Colormap`, default: :rc:`image.cmap`
(8)                 The colormap to use.  This parameter is ignored, unless *mappable* is
(8)                 None.
(4)             norm : `~matplotlib.colors.Normalize`
(8)                 The normalization to use.  This parameter is ignored, unless
*mappable*
(8)                 is None.
(4)             alpha : float
(8)                 The colorbar transparency between 0 (transparent) and 1 (opaque).
(4)             orientation : None or {'vertical', 'horizontal'}
(8)                 If None, use the value determined by *location*. If both
(8)                 *orientation* and *location* are None then defaults to 'vertical'.
(4)             ticklocation : {'auto', 'left', 'right', 'top', 'bottom'}
(8)                 The location of the colorbar ticks. The *ticklocation* must match
(8)                 *orientation*. For example, a horizontal colorbar can only have ticks
(8)                 at the top or the bottom. If 'auto', the ticks will be the same as
(8)                 *location*, so a colorbar to the left will have ticks to the left. If
(8)                 *location* is None, the ticks will be at the bottom for a horizontal
(8)                 colorbar and at the right for a vertical.
(4)             %(_colormap_kw_doc)s
(4)             location : None or {'left', 'right', 'top', 'bottom'}
(8)                 Set the *orientation* and *ticklocation* of the colorbar using a
(8)                 single argument. Colorbars on the left and right are vertical,
(8)                 colorbars at the top and bottom are horizontal. The *ticklocation* is
(8)                 the same as *location*, so if *location* is 'top', the ticks are on
(8)                 the top. *orientation* and/or *ticklocation* can be provided as well
(8)                 and overrides the value set by *location*, but there will be an error
(8)                 for incompatible combinations.
(8)                 .. versionadded:: 3.7

(8)                     [*Discouraged*] Set tick labels.
(8)                     .. admonition:: Discouraged
(12)                        The use of this method is discouraged, because of the dependency
(12)                        on tick positions. In most cases, you'll want to use
(12)                        ``set_ticks(positions, labels=labels)`` instead.
(12)                        If you are using this method, you should always fix the tick
(12)                        positions before, e.g. by using `.Colorbar.set_ticks` or by
(12)                        explicitly setting a `~.ticker.FixedLocator` on the long axis
(12)                        of the colorbar. Otherwise, ticks are free to move and the
(12)                        labels may end up in unexpected positions.
(8)                     Parameters
(8)                     ----------
(8)                     ticklabels : sequence of str or of `.Text`
(12)                        Texts for labeling each tick location in the sequence set by
(12)                        `.Colorbar.set_ticks`; the number of labels must match the number
(12)                        of locations.

(4)             Create an `~.axes.Axes` suitable for a colorbar.
(4)             The Axes is placed in the figure of the *parent* Axes, by resizing and
(4)             repositioning *parent*.
(4)             This function is similar to `.make_axes` and mostly compatible with it.
(4)             Primary differences are
(4)             - `.make_axes_gridspec` requires the *parent* to have a subplotspec.
(4)             - `.make_axes` positions the Axes in figure coordinates;
(6)               `.make_axes_gridspec` positions it using a subplotspec.
(4)             - `.make_axes` updates the position of the parent.  `.make_axes_gridspec`
(6)               replaces the parent gridspec with a new one.
(4)             Parameters
(4)             ----------
(4)             parent : `~matplotlib.axes.Axes`
(8)                 The Axes to use as parent for placing the colorbar.
(4)             %(_make_axes_kw_doc)s
(4)             Returns
(4)             -------

```
1: (0)              """
2: (0)              A module for converting numbers or color arguments to *RGB* or *RGBA*.
3: (0)              *RGB* and *RGBA* are sequences of, respectively, 3 or 4 floats in the
4: (0)              range 0-1.
5: (0)              This module includes functions and classes for color specification
conversions,
6: (0)              and for mapping numbers to colors in a 1-D array of colors called a colormap.
7: (0)              Mapping data onto colors using a colormap typically involves two steps: a data
8: (0)              array is first mapped onto the range 0-1 using a subclass of `Normalize`,
9: (0)              then this number is mapped to a color using a subclass of `Colormap`.  Two
10: (0)             subclasses of `Colormap` provided here:  `LinearSegmentedColormap`, which uses
```

```
 11: (0)             piecewise-linear interpolation to define colormaps, and `ListedColormap`,
 which
 12: (0)             makes a colormap from a list of colors.
 13: (0)             .. seealso::
 14: (2)               :ref:`colormap-manipulation` for examples of how to
 15: (2)               make colormaps and
 16: (2)               :ref:`colormaps` for a list of built-in colormaps.
 17: (2)               :ref:`colormapnorms` for more details about data
 18: (2)               normalization
 19: (2)               More colormaps are available at palettable_.
 20: (0)             The module also provides functions for checking whether an object can be
 21: (0)             interpreted as a color (`is_color_like`), for converting such an object
 22: (0)             to an RGBA tuple (`to_rgba`) or to an HTML-like hex string in the
 23: (0)             "#rrggbb" format (`to_hex`), and a sequence of colors to an (n, 4)
 24: (0)             RGBA array (`to_rgba_array`).  Caching is used for efficiency.
 25: (0)             Colors that Matplotlib recognizes are listed at
 26: (0)             :ref:`colors_def`.

(4)                 r"""
(4)                 Create an *N* -element 1D lookup table.
(4)                 This assumes a mapping :math:`f : [0, 1] \rightarrow [0, 1]`. The returned
(4)                 data is an array of N values :math:`y = f(x)` where x is sampled from
(4)                 [0, 1].
(4)                 By default (*gamma* = 1) x is equidistantly sampled from [0, 1]. The
(4)                 *gamma* correction factor :math:`\gamma` distorts this equidistant
(4)                 sampling by :math:`x \rightarrow x^\gamma`.
(4)                 Parameters
(4)                 ----------
(4)                 N : int
(8)                     The number of elements of the created lookup table; at least 1.
(4)                 data : (M, 3) array-like or callable
(8)                     Defines the mapping :math:`f`.
(8)                     If a (M, 3) array-like, the rows define values (x, y0, y1).  The x
(8)                     values must start with x=0, end with x=1, and all x values be in
(8)                     increasing order.
(8)                     A value between :math:`x_i` and :math:`x_{i+1}` is mapped to the range
(8)                     :math:`y^1_{i-1} \ldots y^0_i` by linear interpolation.
(8)                     For the simple case of a y-continuous mapping, y0 and y1 are
identical.
(8)                     The two values of y are to allow for discontinuous mapping functions.
(8)                     E.g. a sawtooth with a period of 0.2 and an amplitude of 1 would be::
(12)                        [(0, 1, 0), (0.2, 1, 0), (0.4, 1, 0), ..., [(1, 1, 0)]
(8)                     In the special case of ``N == 1``, by convention the returned value
(8)                     is y0 for x == 1.
(8)                     If *data* is a callable, it must accept and return numpy arrays::
(11)                       data(x : ndarray) -> ndarray
(8)                     and map values between 0 - 1 to 0 - 1.
(4)                 gamma : float
(8)                     Gamma correction factor for input distribution x of the mapping.
(8)                     See also https://en.wikipedia.org/wiki/Gamma_correction.
(4)                 Returns
(4)                 -------
(4)                 array

762: (4)                The lookup table is generated using linear interpolation for each
```

```
(4)                 primary color, with the 0-1 domain divided into any number of
(4)                 segments.
(4)                 """
(4)                 def __init__(self, name, segmentdata, N=256, gamma=1.0):
(8)                     """
(8)                     Create colormap from linear mapping segments
(8)                     segmentdata argument is a dictionary with a red, green and blue
(8)                     entries. Each entry should be a list of *x*, *y0*, *y1* tuples,
(8)                     forming rows in a table. Entries for alpha are optional.
(8)                     Example: suppose you want red to increase from 0 to 1 over
(8)                     the bottom half, green to do the same over the middle half,
(8)                     and blue over the top half.  Then you would use::
(12)                        cdict = {'red':   [(0.0,  0.0, 0.0),
(31)                                           (0.5,  1.0, 1.0),
(31)                                           (1.0,  1.0, 1.0)],
(21)                                 'green': [(0.0,  0.0, 0.0),
(31)                                           (0.25, 0.0, 0.0),
(31)                                           (0.75, 1.0, 1.0),
(31)                                           (1.0,  1.0, 1.0)],
(21)                                 'blue':  [(0.0,  0.0, 0.0),
(31)                                           (0.5,  0.0, 0.0),
(31)                                           (1.0,  1.0, 1.0)]}
(8)                     Each row in the table for a given color is a sequence of
(8)                     *x*, *y0*, *y1* tuples.  In each sequence, *x* must increase
(8)                     monotonically from 0 to 1.  For any input value *z* falling
(8)                     between *x[i]* and *x[i+1]*, the output value of a given color
(8)                     will be linearly interpolated between *y1[i]* and *y0[i+1]*::
(12)                        row i:   x  y0  y1
(27)                                       /
(26)                                      /
(12)                        row i+1: x  y0  y1
(8)                     Hence y0 in the first row and y1 in the last row are never used.

(0)             class Normalize:
```

```
    """
    A class which, when called, maps values within the interval
    ``[vmin, vmax]`` linearly to the interval ``[0.0, 1.0]``. The mapping of
    values outside ``[vmin, vmax]`` depends on *clip*.
    Examples
    --------
    ::
        x = [-2, -1, 0, 1, 2]
        norm = mpl.colors.Normalize(vmin=-1, vmax=1, clip=False)
        norm(x)  # [-0.5, 0., 0.5, 1., 1.5]
        norm = mpl.colors.Normalize(vmin=-1, vmax=1, clip=True)
        norm(x)  # [0., 0., 0.5, 1., 1.]
    See Also
    --------
    :ref:`colormapnorms`
    """
    def __init__(self, vmin=None, vmax=None, clip=False):
        """
        Parameters
        ----------
        vmin, vmax : float or None
            Values within the range ``[vmin, vmax]`` from the input data will be

            linearly mapped to ``[0, 1]``. If either *vmin* or *vmax* is not
            provided, they default to the minimum and maximum values of the input,

            respectively.
        clip : bool, default: False
            Determines the behavior for mapping values outside the range
            ``[vmin, vmax]``.
            If clipping is off, values outside the range ``[vmin, vmax]`` are
            also transformed, resulting in values outside ``[0, 1]``.  This
            behavior is usually desirable, as colormaps can mark these *under*
            and *over* values with specific colors.
            If clipping is on, values below *vmin* are mapped to 0 and values
            above *vmax* are mapped to 1. Such values become indistinguishable
            from regular boundary values, which may cause misinterpretation of
            the data.
        Notes
        -----
        If ``vmin == vmax``, input data will be mapped to 0.

```

```
(8)                 Normalize symmetrical data around a center (0 by default).
(8)                 Unlike `TwoSlopeNorm`, `CenteredNorm` applies an equal rate of change
(8)                 around the center.
(8)                 Useful when mapping symmetrical data around a conceptual center
(8)                 e.g., data that range from -2 to 4, with 0 as the midpoint, and
(8)                 with equal rates of change around that midpoint.
(8)                 Parameters
(8)                 ----------
(8)                 vcenter : float, default: 0
(12)                    The data value that defines ``0.5`` in the normalization.
(8)                 halfrange : float, optional
(12)                    The range of data values that defines a range of ``0.5`` in the
(12)                    normalization, so that *vcenter* - *halfrange* is ``0.0`` and
(12)                    *vcenter* + *halfrange* is ``1.0`` in the normalization.
(12)                    Defaults to the largest absolute difference to *vcenter* for
(12)                    the values in the dataset.
(8)                 clip : bool, default: False
(12)                    Determines the behavior for mapping values outside the range
(12)                    ``[vmin, vmax]``.
(12)                    If clipping is off, values outside the range ``[vmin, vmax]`` are
(12)                    also transformed, resulting in values outside ``[0, 1]``.  This
(12)                    behavior is usually desirable, as colormaps can mark these *under*
(12)                    and *over* values with specific colors.
(12)                    If clipping is on, values below *vmin* are mapped to 0 and values
(12)                    above *vmax* are mapped to 1. Such values become indistinguishable
(12)                    from regular boundary values, which may cause misinterpretation of
(12)                    the data.
(8)                 Examples
(8)                 --------
(8)                 This maps data values -2 to 0.25, 0 to 0.5, and 4 to 1.0
(8)                 (assuming equal rates of change above and below 0.0):
(12)                    >>> import matplotlib.colors as mcolors
(12)                    >>> norm = mcolors.CenteredNorm(halfrange=4.0)
(12)                    >>> data = [-2., 0., 4.]
(12)                    >>> norm(data)
(12)                    array([0.25, 0.5 , 1.  ])
(8)                 """

1635: (12)                      falling in the n-th bin will be mapped to the n-th color.
1636: (8)                   ncolors : int
1637: (12)                      Number of colors in the colormap to be used.
1638: (8)                   clip : bool, optional
```

```
(12)                    If clip is ``True``, out of range values are mapped to 0 if they
(12)                    are below ``boundaries[0]`` or mapped to ``ncolors - 1`` if they
(12)                    are above ``boundaries[-1]``.
(12)                    If clip is ``False``, out of range values are mapped to -1 if
(12)                    they are below ``boundaries[0]`` or mapped to *ncolors* if they
are
(12)                    above ``boundaries[-1]``. These are then converted to valid
indices
(12)                    by `Colormap.__call__`.
(8)                 extend : {'neither', 'both', 'min', 'max'}, default: 'neither'
(12)                    Extend the number of bins to include one or both of the
(12)                    regions beyond the boundaries.  For example, if ``extend``
(12)                    is 'min', then the color to which the region between the first
(12)                    pair of boundaries is mapped will be distinct from the first
(12)                    color in the colormap, and by default a
(12)                    `~matplotlib.colorbar.Colorbar` will be drawn with
(12)                    the triangle extension on the left or lower end.
(8)                 Notes
(8)                 -----
(8)                 If there are fewer bins (including extensions) than colors, then the
(8)                 color index is chosen by linearly interpolating the ``[0, nbins - 1]``
(8)                 range onto the ``[0, ncolors - 1]`` range, effectively skipping some
(8)                 colors in the middle of the colormap.

(8)                 Combine colormapped data values with an illumination intensity map
(8)                 (a.k.a.  "hillshade") of the values.
```

```
        Parameters
        ----------
        data : 2D array-like
            The height values used to generate a shaded map.
        cmap : `~matplotlib.colors.Colormap`
            The colormap used to color the *data* array. Note that this must be

            a `~matplotlib.colors.Colormap` instance.  For example, rather than

            passing in ``cmap='gist_earth'``, use
            ``cmap=plt.get_cmap('gist_earth')`` instead.
        norm : `~matplotlib.colors.Normalize` instance, optional
            The normalization used to scale values before colormapping. If
            None, the input will be linearly scaled between its min and max.
        blend_mode : {'hsv', 'overlay', 'soft'} or callable, optional
            The type of blending used to combine the colormapped data
            values with the illumination intensity.  Default is
            "overlay".  Note that for most topographic surfaces,
            "overlay" or "soft" appear more visually realistic. If a
            user-defined function is supplied, it is expected to
            combine an (M, N, 3) RGB array of floats (ranging 0 to 1) with
            an (M, N, 1) hillshade array (also 0 to 1).  (Call signature
            ``func(rgb, illum, **kwargs)``) Additional kwargs supplied
            to this function will be passed on to the *blend_mode*
            function.
        vmin : float or None, optional
            The minimum value used in colormapping *data*. If *None* the
            minimum value in *data* is used. If *norm* is specified, then this
            argument will be ignored.
        vmax : float or None, optional
            The maximum value used in colormapping *data*. If *None* the
            maximum value in *data* is used. If *norm* is specified, then this
            argument will be ignored.
        vert_exag : number, optional
            The amount to exaggerate the elevation values by when calculating
            illumination. This can be used either to correct for differences in

            units between the x-y coordinate system and the elevation
            coordinate system (e.g. decimal degrees vs. meters) or to
            exaggerate or de-emphasize topography.
        dx : number, optional
            The x-spacing (columns) of the input *elevation* grid.
        dy : number, optional
            The y-spacing (rows) of the input *elevation* grid.
        fraction : number, optional
            Increases or decreases the contrast of the hillshade.  Values
            greater than one will cause intermediate values to move closer to
            full illumination or shadow (and clipping any values that move
            beyond 0 or 1). Note that this is not visually or mathematically
            the same as vertical exaggeration.
        **kwargs
            Additional kwargs are passed on to the *blend_mode* function.
        Returns
        -------
        `~numpy.ndarray`
            An (M, N, 4) array of floats ranging between 0-1.
        """

def from_levels_and_colors(levels, colors, extend='neither'):
    """
    A helper routine to generate a cmap and a norm instance which
    behave similar to contourf's levels and colors arguments.
    Parameters
    ----------
    levels : sequence of numbers
        The quantization levels used to construct the `BoundaryNorm`.
        Value ``v`` is quantized to level ``i`` if ``lev[i] <= v < lev[i+1]``.
    colors : sequence of colors
        The fill color to use for each level. If *extend* is "neither" there
        must be ``n_level - 1`` colors. For an *extend* of "min" or "max" add
        one extra color, and for an *extend* of "both" add two colors.
    extend : {'neither', 'min', 'max', 'both'}, optional
        The behaviour when a value falls out of range of the given levels.
        See `~.Axes.contourf` for details.
    Returns
    -------
    cmap : `~matplotlib.colors.Colormap`
    norm : `~matplotlib.colors.Normalize`
    """

```

```
68: (8)                     inline : bool, default: True
69: (12)                        If ``True`` the underlying contour is removed where the label is
70: (12)                        placed.
71: (8)                     inline_spacing : float, default: 5
72: (12)                        Space in pixels to leave on each side of label when placing
inline.
73: (12)                        This spacing will be exact for labels at locations where the
74: (12)                        contour is straight, less so for labels on curved contours.
75: (8)                     fmt : `.Formatter` or str or callable or dict, optional
76: (12)                        How the levels are formatted:
77: (12)                        - If a `.Formatter`, it is used to format all levels at once,
using
78: (14)                          its `.Formatter.format_ticks` method.
79: (12)                        - If a str, it is interpreted as a %-style format string.
80: (12)                        - If a callable, it is called with one level at a time and should
81: (14)                          return the corresponding label.
82: (12)                        - If a dict, it should directly map levels to labels.
83: (12)                        The default is to use a standard `.ScalarFormatter`.
84: (8)                     manual : bool or iterable, default: False
85: (12)                        If ``True``, contour labels will be placed manually using
86: (12)                        mouse clicks. Click the first button near a contour to
87: (12)                        add a label, click the second button (or potentially both
88: (12)                        mouse buttons at once) to finish adding labels. The third
89: (12)                        button can be used to remove the last label added, but
90: (12)                        only if labels are not inline. Alternatively, the keyboard
91: (12)                        can be used to select label locations (enter to end label
92: (12)                        placement, delete or backspace act like the third mouse button,
93: (12)                        and any other key will select a label location).
94: (12)                        *manual* can also be an iterable object of (x, y) tuples.
95: (12)                        Contour labels will be created as if mouse is clicked at each
96: (12)                        (x, y) position.
97: (8)                     rightside_up : bool, default: True
98: (12)                        If ``True``, label rotations will always be plus
99: (12)                        or minus 90 degrees from level.
100: (8)                    use_clabeltext : bool, default: False
101: (12)                       If ``True``, use `.Text.set_transform_rotates_text` to ensure that
102: (12)                       label rotation is updated whenever the Axes aspect changes.
103: (8)                    zorder : float or None, default: ``(2 + contour.get_zorder())``
104: (12)                       zorder of the contour labels.
105: (8)                    Returns
106: (8)                    -------
107: (8)                    labels
108: (12)                       A list of `.Text` instances for the labels.

(8)                     Color argument processing for contouring.
(8)                     Note that we base the colormapping on the contour levels
(8)                     and layers, not on the actual range of the Z values.  This
(8)                     means we don't have to worry about bad values in Z, and we
(8)                     always have the full dynamic range available for the selected
(8)                     levels.
(8)                     The color is based on the midpoint of the layer, except for
(8)                     extended end layers.  By default, the norm vmin and vmax
(8)                     are the extreme values of the non-extended levels.  Hence,
(8)                     the layer color extremes are not the extreme values of
(8)                     the colormap itself, but approach those values as the number
(8)                     of levels increases.  An advantage of this scheme is that
(8)                     line contours, when added to filled contours, take on
(8)                     colors that are consistent with those of the filled regions;
(8)                     for example, a contour line on the boundary between two
(8)                     regions will have a color intermediate between those
(8)                     of the regions.

(16)                        y = np.linspace(y0, y1, Ny)
(16)                        return np.meshgrid(x, y)
(8)                 if self.extent is None:
(12)                    x0, x1, y0, y1 = (0, Nx, 0, Ny)
(8)                 else:
(12)                    x0, x1, y0, y1 = self.extent
(8)                 dx = (x1 - x0) / Nx
(8)                 dy = (y1 - y0) / Ny
(8)                 x = x0 + (np.arange(Nx) + 0.5) * dx
(8)                 y = y0 + (np.arange(Ny) + 0.5) * dy
(8)                 if self.origin == 'upper':
(12)                    y = y[::-1]
(8)                 return np.meshgrid(x, y)
(0)         _docstring.interpd.update(contour_doc="""
(0)         `.contour` and `.contourf` draw contour lines and filled contours,
(0)         respectively.  Except as noted, function signatures and return values
(0)         are the same for both versions.
(0)         Parameters
(0)         ----------
(0)         X, Y : array-like, optional
(4)             The coordinates of the values in *Z*.
(4)             *X* and *Y* must both be 2D with the same shape as *Z* (e.g.
```

```
(4)             created via `numpy.meshgrid`), or they must both be 1-D such
(4)             that ``len(X) == N`` is the number of columns in *Z* and
(4)             ``len(Y) == M`` is the number of rows in *Z*.
(4)             *X* and *Y* must both be ordered monotonically.
(4)             If not given, they are assumed to be integer indices, i.e.
(4)             ``X = range(N)``, ``Y = range(M)``.
(0)         Z : (M, N) array-like
(4)             The height values over which the contour is drawn.  Color-mapping is
(4)             controlled by *cmap*, *norm*, *vmin*, and *vmax*.
(0)         levels : int or array-like, optional
(4)             Determines the number and positions of the contour lines / regions.
(4)             If an int *n*, use `~matplotlib.ticker.MaxNLocator`, which tries
(4)             to automatically choose no more than *n+1* "nice" contour levels
(4)             between minimum and maximum numeric values of *Z*.
(4)             If array-like, draw contour lines at the specified levels.
(4)             The values must be in increasing order.
(0)         Returns
(0)         -------
(0)         `~.contour.QuadContourSet`
(0)         Other Parameters
(0)         ----------------
(0)         corner_mask : bool, default: :rc:`contour.corner_mask`
(4)             Enable/disable corner masking, which only has an effect if *Z* is
(4)             a masked array.  If ``False``, any quad touching a masked point is
(4)             masked out.  If ``True``, only the triangular corners of quads
(4)             nearest those points are always masked out, other triangular
(4)             corners comprising three unmasked points are contoured as usual.
(0)         colors : :mpltype:`color` or list of :mpltype:`color`, optional
(4)             The colors of the levels, i.e. the lines for `.contour` and the
(4)             areas for `.contourf`.
(4)             The sequence is cycled for the levels in ascending order. If the
(4)             sequence is shorter than the number of levels, it's repeated.
(4)             As a shortcut, single color strings may be used in place of
(4)             one-element lists, i.e. ``'red'`` instead of ``['red']`` to color
(4)             all levels with the same color. This shortcut does only work for
(4)             color strings, not for other ways of specifying colors.
(4)             By default (value *None*), the colormap specified by *cmap*
(4)             will be used.
(0)         alpha : float, default: 1
(4)             The alpha blending value, between 0 (transparent) and 1 (opaque).
(0)         %(cmap_doc)s
(4)             This parameter is ignored if *colors* is set.
(0)         %(norm_doc)s
(4)             This parameter is ignored if *colors* is set.
(0)         %(vmin_vmax_doc)s
(4)             If *vmin* or *vmax* are not given, the default color scaling is based on
(4)             *levels*.
(4)             This parameter is ignored if *colors* is set.
(0)         origin : {*None*, 'upper', 'lower', 'image'}, default: None
(4)             Determines the orientation and exact position of *Z* by specifying
(4)             the position of ``Z[0, 0]``.  This is only relevant, if *X*, *Y*
(4)             are not given.
(4)             - *None*: ``Z[0, 0]`` is at X=0, Y=0 in the lower left corner.
(4)             - 'lower': ``Z[0, 0]`` is at X=0.5, Y=0.5 in the lower left corner.
(4)             - 'upper': ``Z[0, 0]`` is at X=N+0.5, Y=0.5 in the upper left
(6)               corner.
(4)             - 'image': Use the value from :rc:`image.origin`.
(0)         extent : (x0, x1, y0, y1), optional
(4)             If *origin* is not *None*, then *extent* is interpreted as in
(4)             `.imshow`: it gives the outer pixel boundaries. In this case, the
(4)             position of Z[0, 0] is the center of the pixel, not a corner. If
(4)             *origin* is *None*, then (*x0*, *y0*) is the position of Z[0, 0],
(4)             and (*x1*, *y1*) is the position of Z[-1, -1].
(4)             This argument is ignored if *X* and *Y* are specified in the call
(4)             to contour.
(0)         locator : ticker.Locator subclass, optional
(4)             The locator is used to determine the contour levels if they
(4)             are not given explicitly via *levels*.
(4)             Defaults to `~.ticker.MaxNLocator`.
```

```
(0)           extend : {'neither', 'both', 'min', 'max'}, default: 'neither'
(4)               Determines the ``contourf``-coloring of values that are outside the
(4)               *levels* range.
(4)               If 'neither', values outside the *levels* range are not colored.
(4)               If 'min', 'max' or 'both', color the values below, above or below
(4)               and above the *levels* range.
(4)               Values below ``min(levels)`` and above ``max(levels)`` are mapped
(4)               to the under/over values of the `.Colormap`. Note that most
(4)               colormaps do not have dedicated colors for these by default, so
(4)               that the over and under values are the edge values of the colormap.
(4)               You may want to set these values explicitly using
(4)               `.Colormap.set_under` and `.Colormap.set_over`.
(4)               .. note::
(8)                   An existing `.QuadContourSet` does not get notified if
(8)                   properties of its colormap are changed. Therefore, an explicit
(8)                   call `.QuadContourSet.changed()` is needed after modifying the
(8)                   colormap. The explicit call can be left out, if a colorbar is
(8)                   assigned to the `.QuadContourSet` because it internally calls
(8)                   `.QuadContourSet.changed()`.
(4)               Example::
(8)                   x = np.arange(1, 10)
(8)                   y = x.reshape(-1, 1)
(8)                   h = x * y
(8)                   cs = plt.contourf(h, levels=[10, 30, 50],
(12)                      colors=['#808080', '#A0A0A0', '#C0C0C0'], extend='both')
(8)                   cs.cmap.set_over('red')
(8)                   cs.cmap.set_under('blue')
(8)                   cs.changed()
(0)           xunits, yunits : registered units, optional
(4)               Override axis units by specifying an instance of a
(4)               :class:`matplotlib.units.ConversionInterface`.
(0)           antialiased : bool, optional
(4)               Enable antialiasing, overriding the defaults.  For
(4)               filled contours, the default is *False*.  For line contours,
(4)               it is taken from :rc:`lines.antialiased`.
(0)           nchunk : int >= 0, optional
(4)               If 0, no subdivision of the domain.  Specify a positive integer to
(4)               divide the domain into subdomains of *nchunk* by *nchunk* quads.
(4)               Chunking reduces the maximum length of polygons generated by the
(4)               contouring algorithm which reduces the rendering workload passed
(4)               on to the backend and also requires slightly less RAM.  It can
(4)               however introduce rendering artifacts at chunk boundaries depending
(4)               on the backend, the *antialiased* flag and value of *alpha*.
(0)           linewidths : float or array-like, default: :rc:`contour.linewidth`
(4)               *Only applies to* `.contour`.
(4)               The line width of the contour lines.
(4)               If a number, all levels will be plotted with this linewidth.
(4)               If a sequence, the levels in ascending order will be plotted with
(4)               the linewidths in the order specified.
(4)               If None, this falls back to :rc:`lines.linewidth`.
(0)           linestyles : {*None*, 'solid', 'dashed', 'dashdot', 'dotted'}, optional
(4)               *Only applies to* `.contour`.
(4)               If *linestyles* is *None*, the default is 'solid' unless the lines are
(4)               monochrome. In that case, negative contours will instead take their
(4)               linestyle from the *negative_linestyles* argument.
(4)               *linestyles* can also be an iterable of the above strings specifying a set
(4)               of linestyles to be used. If this iterable is shorter than the number of
(4)               contour levels it will be repeated as necessary.
(0)           negative_linestyles : {*None*, 'solid', 'dashed', 'dashdot', 'dotted'}, \
(23)                                optional
(4)               *Only applies to* `.contour`.
(4)               If *linestyles* is *None* and the lines are monochrome, this argument
(4)               specifies the line style for negative contours.
(4)               If *negative_linestyles* is *None*, the default is taken from
(4)               :rc:`contour.negative_linestyles`.
(4)               *negative_linestyles* can also be an iterable of the above strings
(4)               specifying a set of linestyles to be used. If this iterable is shorter
than
(4)               the number of contour levels it will be repeated as necessary.
```

```
1412: (0)           hatches : list[str], optional
1413: (4)               *Only applies to* `.contourf`.
1414: (4)               A list of cross hatch patterns to use on the filled areas.
1415: (4)               If None, no hatching will be added to the contour.
1416: (0)           algorithm : {'mpl2005', 'mpl2014', 'serial', 'threaded'}, optional
1417: (4)               Which contouring algorithm to use to calculate the contour lines and
1418: (4)               polygons. The algorithms are implemented in
1419: (4)               `ContourPy <https://github.com/contourpy/contourpy>`_, consult the
1420: (4)               `ContourPy documentation <https://contourpy.readthedocs.io>`_ for
1421: (4)               further information.
1422: (4)               The default is taken from :rc:`contour.algorithm`.
1423: (0)           clip_path : `~matplotlib.patches.Patch` or `.Path` or `.TransformedPath`
1424: (4)               Set the clip path.  See `~matplotlib.artist.Artist.set_clip_path`.
1425: (4)               .. versionadded:: 3.8
1426: (0)           data : indexable object, optional
1427: (4)               DATA_PARAMETER_PLACEHOLDER
1428: (0)           Notes
1429: (0)           -----
1430: (0)           1. `.contourf` differs from the MATLAB version in that it does not draw
1431: (3)              the polygon edges. To draw edges, add line contours with calls to
1432: (3)              `.contour`.
1433: (0)           2. `.contourf` fills intervals that are closed at the top; that is, for
1434: (3)              boundaries *z1* and *z2*, the filled region is::
1435: (6)                 z1 < Z <= z2
1436: (3)              except for the lowest interval, which is closed on both sides (i.e.
1437: (3)              it includes the lowest value).
1438: (0)           3. `.contour` and `.contourf` use a `marching squares
1439: (3)              <https://en.wikipedia.org/wiki/Marching_squares>`_ algorithm to
1440: (3)              compute contour locations.  More information can be found in
1441: (3)              `ContourPy documentation <https://contourpy.readthedocs.io>`_.

```

File 36 - dates.py:

```
1: (0)              """
2: (0)              Matplotlib provides sophisticated date plotting capabilities, standing on the
3: (0)              shoulders of python :mod:`datetime` and the add-on module dateutil_.
4: (0)              By default, Matplotlib uses the units machinery described in
5: (0)              `~matplotlib.units` to convert `datetime.datetime`, and `numpy.datetime64`
6: (0)              objects when plotted on an x- or y-axis. The user does not
7: (0)              need to do anything for dates to be formatted, but dates often have strict
8: (0)              formatting needs, so this module provides many tick locators and formatters.
9: (0)              A basic example using `numpy.datetime64` is::
10: (4)                 import numpy as np
11: (4)                 times = np.arange(np.datetime64('2001-01-02'),
12: (22)                                  np.datetime64('2002-02-03'), np.timedelta64(75, 'm'))
13: (4)                 y = np.random.randn(len(times))
14: (4)                 fig, ax = plt.subplots()
15: (4)                 ax.plot(times, y)
16: (0)             .. seealso::
17: (4)                 - :doc:`/gallery/text_labels_and_annotations/date`
18: (4)                 - :doc:`/gallery/ticks/date_concise_formatter`
19: (4)                 - :doc:`/gallery/ticks/date_demo_convert`
20: (0)             .. _date-format:
21: (0)             Matplotlib date format
22: (0)             ----------------------
23: (0)             Matplotlib represents dates using floating point numbers specifying the number
24: (0)             of days since a default epoch of 1970-01-01 UTC; for example,
25: (0)             1970-01-01, 06:00 is the floating point number 0.25. The formatters and
26: (0)             locators require the use of `datetime.datetime` objects, so only dates between
27: (0)             year 0001 and 9999 can be represented.  Microsecond precision
28: (0)             is achievable for (approximately) 70 years on either side of the epoch, and
29: (0)             20 microseconds for the rest of the allowable range of dates (year 0001 to
30: (0)             9999). The epoch can be changed at import time via `.dates.set_epoch` or
31: (0)             :rc:`dates.epoch` to other dates if necessary; see
32: (0)             :doc:`/gallery/ticks/date_precision_and_epochs` for a discussion.
33: (0)             .. note::
```

```
  34: (3)                Before Matplotlib 3.3, the epoch was 0000-12-31 which lost modern
  35: (3)                microsecond precision and also made the default axis limit of 0 an invalid
  36: (3)                datetime.  In 3.3 the epoch was changed as above.  To convert old
  37: (3)                ordinal floats to the new epoch, users can do::
  38: (5)                  new_ordinal = old_ordinal + mdates.date2num(np.datetime64('0000-12-31'))
  39: (0)             There are a number of helper functions to convert between :mod:`datetime`
  40: (0)             objects and Matplotlib dates:
  41: (0)             .. currentmodule:: matplotlib.dates
  42: (0)             .. autosummary::
  43: (3)                :nosignatures:
  44: (3)                datestr2num
  45: (3)                date2num
  46: (3)                num2date
  47: (3)                num2timedelta
  48: (3)                drange
  49: (3)                set_epoch
  50: (3)                get_epoch
  51: (0)             .. note::
  52: (3)                Like Python's `datetime.datetime`, Matplotlib uses the Gregorian calendar
  53: (3)                for all conversions between dates and floating point numbers. This practice
  54: (3)                is not universal, and calendar differences can cause confusing
  55: (3)                differences between what Python and Matplotlib give as the number of days
  56: (3)                since 0001-01-01 and what other software and databases yield.  For
  57: (3)                example, the US Naval Observatory uses a calendar that switches
  58: (3)                from Julian to Gregorian in October, 1582.  Hence, using their
  59: (3)                calculator, the number of days between 0001-01-01 and 2006-04-01 is
  60: (3)                732403, whereas using the Gregorian calendar via the datetime
  61: (3)                module we find::
  62: (5)                  In [1]: date(2006, 4, 1).toordinal() - date(1, 1, 1).toordinal()
  63: (5)                  Out[1]: 732401
  64: (0)             All the Matplotlib date converters, locators and formatters are timezone
  aware.
  65: (0)             If no explicit timezone is provided, :rc:`timezone` is assumed, provided as a
  66: (0)             string.  If you want to use a different timezone, pass the *tz* keyword
  67: (0)             argument of `num2date` to any date tick locators or formatters you create.
  This
  68: (0)             can be either a `datetime.tzinfo` instance or a string with the timezone name
  69: (0)             that can be parsed by `~dateutil.tz.gettz`.
  70: (0)             A wide range of specific and general purpose date tick locators and
  71: (0)             formatters are provided in this module.  See
  72: (0)             :mod:`matplotlib.ticker` for general information on tick locators
  73: (0)             and formatters.  These are described below.
  74: (0)             The dateutil_ module provides additional code to handle date ticking, making
  it
  75: (0)             easy to place ticks on any kinds of dates.  See examples below.
  76: (0)             .. _dateutil: https://dateutil.readthedocs.io
  77: (0)             .. _date-locators:
  78: (0)             Date tick locators
  79: (0)             ------------------
  80: (0)             Most of the date tick locators can locate single or multiple ticks. For
  example::
  81: (4)                 from matplotlib.dates import MO, TU, WE, TH, FR, SA, SU
  82: (4)                 loc = WeekdayLocator(byweekday=MO, tz=tz)
  83: (4)                 loc = WeekdayLocator(byweekday=(MO, SA))
  84: (0)             In addition, most of the constructors take an interval argument::
  85: (4)                 loc = WeekdayLocator(byweekday=MO, interval=2)
  86: (0)             The rrule locator allows completely general date ticking::
  87: (4)                 rule = rrulewrapper(YEARLY, byeaster=1, interval=5)
  88: (4)                 loc = RRuleLocator(rule)
  89: (0)             The available date tick locators are:
  90: (0)             * `MicrosecondLocator`: Locate microseconds.
  91: (0)             * `SecondLocator`: Locate seconds.
  92: (0)             * `MinuteLocator`: Locate minutes.
  93: (0)             * `HourLocator`: Locate hours.
  94: (0)             * `DayLocator`: Locate specified days of the month.
  95: (0)             * `WeekdayLocator`: Locate days of the week, e.g., MO, TU.
  96: (0)             * `MonthLocator`: Locate months, e.g., 7 for July.
  97: (0)             * `YearLocator`: Locate years that are multiples of base.
  98: (0)             * `RRuleLocator`: Locate using a `rrulewrapper`.
```

```
 99: (2)                `rrulewrapper` is a simple wrapper around dateutil_'s `dateutil.rrule`
100: (2)                which allow almost arbitrary date tick specifications.
101: (2)                See :doc:`rrule example </gallery/ticks/date_demo_rrule>`.
102: (0)              * `AutoDateLocator`: On autoscale, this class picks the best `DateLocator`
103: (2)                (e.g., `RRuleLocator`) to set the view limits and the tick locations.  If
104: (2)                called with ``interval_multiples=True`` it will make ticks line up with
105: (2)                sensible multiples of the tick intervals.  For example, if the interval is
106: (2)                4 hours, it will pick hours 0, 4, 8, etc. as ticks.  This behaviour is not
107: (2)                guaranteed by default.
108: (0)              .. _date-formatters:
109: (0)              Date formatters
110: (0)              ---------------
111: (0)              The available date formatters are:
112: (0)              * `AutoDateFormatter`: attempts to figure out the best format to use.  This is
113: (2)                most useful when used with the `AutoDateLocator`.
114: (0)              * `ConciseDateFormatter`: also attempts to figure out the best format to use,
115: (2)                and to make the format as compact as possible while still having complete
116: (2)                date information.  This is most useful when used with the `AutoDateLocator`.
117: (0)              * `DateFormatter`: use `~datetime.datetime.strftime` format strings.
118: (0)              """

422: (4)                """
423: (4)                A `.Formatter` which attempts to figure out the best format to use for the
424: (4)                date, and to make it as compact as possible, but still be complete. This
is
425: (4)                most useful when used with the `AutoDateLocator`::
426: (4)                >>> locator = AutoDateLocator()
427: (4)                >>> formatter = ConciseDateFormatter(locator)
428: (4)                Parameters
429: (4)                ----------
430: (4)                locator : `.ticker.Locator`
431: (8)                    Locator that this axis is using.
432: (4)                tz : str or `~datetime.tzinfo`, default: :rc:`timezone`
433: (8)                    Ticks timezone, passed to `.dates.num2date`.
434: (4)                formats : list of 6 strings, optional
435: (8)                    Format strings for 6 levels of tick labelling: mostly years,
436: (8)                    months, days, hours, minutes, and seconds.  Strings use
437: (8)                    the same format codes as `~datetime.datetime.strftime`.  Default is
438: (8)                    ``['%Y', '%b', '%d', '%H:%M', '%H:%M', '%S.%f']``
439: (4)                zero_formats : list of 6 strings, optional
440: (8)                    Format strings for tick labels that are "zeros" for a given tick
441: (8)                    level.  For instance, if most ticks are months, ticks around 1 Jan
```

```
2005
                    will be labeled "Dec", "2005", "Feb".  The default is
                    ``['', '%Y', '%b', '%b-%d', '%H:%M', '%H:%M']``
                offset_formats : list of 6 strings, optional
                    Format strings for the 6 levels that is applied to the "offset"
                    string found on the right side of an x-axis, or top of a y-axis.
                    Combined with the tick labels this should completely specify the
                    date.  The default is::
                        ['', '%Y', '%Y-%b', '%Y-%b-%d', '%Y-%b-%d', '%Y-%b-%d %H:%M']
                show_offset : bool, default: True
                    Whether to show the offset or not.
                usetex : bool, default: :rc:`text.usetex`
                    To enable/disable the use of TeX's math mode for rendering the results
                    of the formatter.

(0)             class AutoDateFormatter(ticker.Formatter):
```

```
(4)                 """
(4)                 A `.Formatter` which attempts to figure out the best format to use.  This
(4)                 is most useful when used with the `AutoDateLocator`.
(4)                 `.AutoDateFormatter` has a ``.scale`` dictionary that maps tick scales (the
(4)                 interval in days between one major tick) to format strings; this dictionary
(4)                 defaults to ::
(8)                     self.scaled = {
(12)                        DAYS_PER_YEAR: rcParams['date.autoformatter.year'],
(12)                        DAYS_PER_MONTH: rcParams['date.autoformatter.month'],
(12)                        1: rcParams['date.autoformatter.day'],
(12)                        1 / HOURS_PER_DAY: rcParams['date.autoformatter.hour'],
(12)                        1 / MINUTES_PER_DAY: rcParams['date.autoformatter.minute'],
(12)                        1 / SEC_PER_DAY: rcParams['date.autoformatter.second'],
(12)                        1 / MUSECONDS_PER_DAY: rcParams['date.autoformatter.microsecond'],
(8)                     }
(4)                 The formatter uses the format string corresponding to the lowest key in
(4)                 the dictionary that is greater or equal to the current scale.  Dictionary
(4)                 entries can be customized::
(8)                     locator = AutoDateLocator()
(8)                     formatter = AutoDateFormatter(locator)
(8)                     formatter.scaled[1/(24*60)] = '%M:%S' # only show min and sec
(4)                 Custom callables can also be used instead of format strings.  The following
(4)                 example shows how to use a custom format function to strip trailing zeros
(4)                 from decimal seconds and adds the date to the first ticklabel::
(8)                     def my_format_function(x, pos=None):
(12)                        x = matplotlib.dates.num2date(x)
(12)                        if pos == 0:
(16)                            fmt = '%D %H:%M:%S.%f'
(12)                        else:
(16)                            fmt = '%H:%M:%S.%f'
(12)                        label = x.strftime(fmt)
(12)                        label = label.rstrip("0")
(12)                        label = label.rstrip(".")
(12)                        return label
(8)                     formatter.scaled[1/(24*60)] = my_format_function
(4)                 """

(4)             Make ticks on regular intervals of one or more microsecond(s).
(4)             .. note::
(8)                 By default, Matplotlib uses a floating point representation of time in
(8)                 days since the epoch, so plotting data with
(8)                 microsecond time resolution does not work well for
(8)                 dates that are far (about 70 years) from the epoch (check with
(8)                 `~.dates.get_epoch`).
(8)                 If you want sub-microsecond resolution time plots, it is strongly
(8)                 recommended to use floating point seconds, not datetime-like
(8)                 time representation.
(8)                 If you really must use datetime.datetime() or similar and still
(8)                 need microsecond precision, change the time origin via
(8)                 `.dates.set_epoch` to something closer to the dates being plotted.
(8)                 See :doc:`/gallery/ticks/date_precision_and_epochs`.

(0)  class DviFont:
(4)     """
(4)     Encapsulation of a font that a DVI file can refer to.
(4)     This class holds a font's texname and size, supports comparison,
(4)     and knows the widths of glyphs in the same units as the AFM file.
(4)     There are also internal attributes (for use by dviread.py) that
(4)     are *not* used for comparison.
(4)     The size is in Adobe points (converted from TeX points).
(4)     Parameters
(4)     ----------
(4)     scale : float
(8)         Factor by which the font is scaled from its natural size.
(4)     tfm : Tfm
(8)         TeX font metrics for this font
(4)     texname : bytes
(7)        Name of the font as used internally by TeX and friends, as an ASCII
(7)        bytestring.  This is usually very different from any external font
(7)        names; `PsfontsMap` can be used to find the external name of the font.
(4)     vf : Vf
(7)        A TeX "virtual font" file, or None if this font is not virtual.
(4)     Attributes
(4)     ----------
(4)     texname : bytes
(4)     size : float
(7)        Size of the font in Adobe points, converted from the slightly
(7)        smaller TeX points.
(4)     widths : list
(7)        Widths of glyphs in glyph-space units, typically 1/1000ths of
(7)        the point size.
(4)     """

599: (4)                """
600: (4)                A psfonts.map formatted file, mapping TeX fonts to PS fonts.
601: (4)                Parameters
602: (4)                ----------
603: (4)                filename : str or path-like
604: (4)                Notes
605: (4)                -----
606: (4)                For historical reasons, TeX knows many Type-1 fonts by different
607: (4)                names than the outside world. (For one thing, the names have to
608: (4)                fit in eight characters.) Also, TeX's native fonts are not Type-1
609: (4)                but Metafont, which is nontrivial to convert to PostScript except
610: (4)                as a bitmap. While high-quality conversions to Type-1 format exist
611: (4)                and are shipped with modern TeX distributions, we need to know
612: (4)                which Type-1 fonts are the counterparts of which native fonts. For
613: (4)                these reasons a mapping is needed from internal font names to font
614: (4)                file names.
615: (4)                A texmf tree typically includes mapping files called e.g.
616: (4)                :file:`psfonts.map`, :file:`pdftex.map`, or :file:`dvipdfm.map`.
617: (4)                The file :file:`psfonts.map` is used by :program:`dvips`,
618: (4)                :file:`pdftex.map` by :program:`pdfTeX`, and :file:`dvipdfm.map`
619: (4)                by :program:`dvipdfm`. :file:`psfonts.map` might avoid embedding
620: (4)                the 35 PostScript fonts (i.e., have no filename for them, as in
621: (4)                the Times-Bold example above), while the pdf-related files perhaps
622: (4)                only avoid the "Base 14" pdf fonts. But the user may have
623: (4)                configured these files differently.
624: (4)                Examples
625: (4)                --------
626: (4)                >>> map = PsfontsMap(find_tex_file('pdftex.map'))
627: (4)                >>> entry = map[b'ptmbo8r']
628: (4)                >>> entry.texname
629: (4)                b'ptmbo8r'
630: (4)                >>> entry.psname

File 38 - figure.py:

1: (0)              """
2: (0)              `matplotlib.figure` implements the following classes:
3: (0)              `Figure`
4: (4)                  Top level `~matplotlib.artist.Artist`, which holds all plot elements.
5: (4)                  Many methods are implemented in `FigureBase`.
6: (0)              `SubFigure`
7: (4)                  A logical figure inside a figure, usually added to a figure (or parent
8: (4)                  `SubFigure`) with `Figure.add_subfigure` or `Figure.subfigures` methods
9: (4)                  (provisional API v3.4).
10: (0)             Figures are typically created using pyplot methods `~.pyplot.figure`,
11: (0)             `~.pyplot.subplots`, and `~.pyplot.subplot_mosaic`.
12: (0)             .. plot::
13: (4)                 :include-source:
14: (4)                 fig, ax = plt.subplots(figsize=(2, 2), facecolor='lightskyblue',
15: (27)                                        layout='constrained')
16: (4)                 fig.suptitle('Figure')
17: (4)                 ax.set_title('Axes', loc='left', fontstyle='oblique', fontsize='medium')
18: (0)             Some situations call for directly instantiating a `~.figure.Figure` class,
19: (0)             usually inside an application of some sort (see :ref:`user_interfaces` for a
20: (0)             list of examples) .  More information about Figures can be found at
21: (0)             :ref:`figure-intro`.

(8)                 """
(8)                 Add an `~.axes.Axes` to the figure.
(8)                 Call signatures::
(12)                    add_axes(rect, projection=None, polar=False, **kwargs)
(12)                    add_axes(ax)
(8)                 Parameters
(8)                 ----------
(8)                 rect : tuple (left, bottom, width, height)
(12)                    The dimensions (left, bottom, width, height) of the new
(12)                    `~.axes.Axes`. All quantities are in fractions of figure width and
(12)                    height.
(8)                 projection : {None, 'aitoff', 'hammer', 'lambert', 'mollweide', \
(0)         'polar', 'rectilinear', str}, optional
(12)                    The projection type of the `~.axes.Axes`. *str* is the name of
(12)                    a custom projection, see `~matplotlib.projections`. The default
(12)                    None results in a 'rectilinear' projection.
(8)                 polar : bool, default: False
(12)                    If True, equivalent to projection='polar'.
(8)                 axes_class : subclass type of `~.axes.Axes`, optional
(12)                    The `.axes.Axes` subclass that is instantiated.  This parameter
(12)                    is incompatible with *projection* and *polar*.  See
(12)                    :ref:`axisartist_users-guide-index` for examples.
(8)                 sharex, sharey : `~matplotlib.axes.Axes`, optional
(12)                    Share the x or y `~matplotlib.axis` with sharex and/or sharey.
(12)                    The axis will have the same limits, ticks, and scale as the axis
```

```
(12)                        of the shared Axes.
(8)                     label : str
(12)                        A label for the returned Axes.
(8)                     Returns
(8)                     -------
(8)                     `~.axes.Axes`, or a subclass of `~.axes.Axes`
(12)                        The returned Axes class depends on the projection used. It is
(12)                        `~.axes.Axes` if rectilinear projection is used and
(12)                        `.projections.polar.PolarAxes` if polar projection is used.
(8)                     Other Parameters
(8)                     ----------------
(8)                     **kwargs
(12)                        This method also takes the keyword arguments for
(12)                        the returned Axes class. The keyword arguments for the
(12)                        rectilinear Axes class `~.axes.Axes` can be found in
(12)                        the following table but there might also be other keyword
(12)                        arguments if another projection is used, see the actual Axes
(12)                        class.
(12)                        %(Axes:kwdoc)s
(8)                     Notes
(8)                     -----
(8)                     In rare circumstances, `.add_axes` may be called with a single
(8)                     argument, an Axes instance already created in the present figure but
(8)                     not in the figure's list of Axes.
(8)                     See Also
