483: (8)                    Call signatures::
484: (11)                      add_subplot(nrows, ncols, index, **kwargs)
485: (11)                      add_subplot(pos, **kwargs)
486: (11)                      add_subplot(ax)
487: (11)                      add_subplot()
488: (8)                    Parameters
489: (8)                    ----------
490: (8)                    *args : int, (int, int, *index*), or `.SubplotSpec`, default: (1, 1,
1)
491: (12)                       The position of the subplot described by one of
492: (12)                       - Three integers (*nrows*, *ncols*, *index*). The subplot will
493: (14)                         take the *index* position on a grid with *nrows* rows and
494: (14)                         *ncols* columns. *index* starts at 1 in the upper left corner
495: (14)                         and increases to the right.  *index* can also be a two-tuple
496: (14)                         specifying the (*first*, *last*) indices (1-based, and including
497: (14)                         *last*) of the subplot, e.g., ``fig.add_subplot(3, 1, (1, 2))``
498: (14)                         makes a subplot that spans the upper 2/3 of the figure.
499: (12)                       - A 3-digit integer. The digits are interpreted as if given
500: (14)                         separately as three single-digit integers, i.e.
501: (14)                         ``fig.add_subplot(235)`` is the same as
502: (14)                         ``fig.add_subplot(2, 3, 5)``. Note that this can only be used
503: (14)                         if there are no more than 9 subplots.
504: (12)                       - A `.SubplotSpec`.
505: (12)                       In rare circumstances, `.add_subplot` may be called with a single
506: (12)                       argument, a subplot Axes instance already created in the
507: (12)                       present figure but not in the figure's list of Axes.
508: (8)                    projection : {None, 'aitoff', 'hammer', 'lambert', 'mollweide', \
509: (0)             'polar', 'rectilinear', str}, optional
510: (12)                       The projection type of the subplot (`~.axes.Axes`). *str* is the
511: (12)                       name of a custom projection, see `~matplotlib.projections`. The
512: (12)                       default None results in a 'rectilinear' projection.
513: (8)                    polar : bool, default: False
514: (12)                       If True, equivalent to projection='polar'.
515: (8)                    axes_class : subclass type of `~.axes.Axes`, optional
516: (12)                       The `.axes.Axes` subclass that is instantiated.  This parameter
517: (12)                       is incompatible with *projection* and *polar*.  See
518: (12)                       :ref:`axisartist_users-guide-index` for examples.
519: (8)                    sharex, sharey : `~matplotlib.axes.Axes`, optional
520: (12)                       Share the x or y `~matplotlib.axis` with sharex and/or sharey.
521: (12)                       The axis will have the same limits, ticks, and scale as the axis
522: (12)                       of the shared Axes.
523: (8)                    label : str
524: (12)                       A label for the returned Axes.
525: (8)                    Returns
526: (8)                    -------
527: (8)                    `~.axes.Axes`
528: (12)                       The Axes of the subplot. The returned Axes can actually be an
529: (12)                       instance of a subclass, such as `.projections.polar.PolarAxes` for
530: (12)                       polar projections.
531: (8)                    Other Parameters
532: (8)                    ----------------
533: (8)                    **kwargs
534: (12)                       This method also takes the keyword arguments for the returned Axes
535: (12)                       base class; except for the *figure* argument. The keyword
arguments
536: (12)                       for the rectilinear base class `~.axes.Axes` can be found in
537: (12)                       the following table but there might also be other keyword
538: (12)                       arguments if another projection is used.
539: (12)                       %(Axes:kwdoc)s

(8)                     Add a set of subplots to this figure.
(8)                     This utility wrapper makes it convenient to create common layouts of
(8)                     subplots in a single call.
(8)                     Parameters
(8)                     ----------
(8)                     nrows, ncols : int, default: 1
(12)                        Number of rows/columns of the subplot grid.
(8)                     sharex, sharey : bool or {'none', 'all', 'row', 'col'}, default: False
(12)                        Controls sharing of x-axis (*sharex*) or y-axis (*sharey*):
(12)                        - True or 'all': x- or y-axis will be shared among all subplots.
(12)                        - False or 'none': each subplot x- or y-axis will be independent.
(12)                        - 'row': each subplot row will share an x- or y-axis.
(12)                        - 'col': each subplot column will share an x- or y-axis.
```

```
(12)                        When subplots have a shared x-axis along a column, only the x tick
(12)                        labels of the bottom subplot are created. Similarly, when subplots
(12)                        have a shared y-axis along a row, only the y tick labels of the
(12)                        first column subplot are created. To later turn other subplots'
(12)                        ticklabels on, use `~matplotlib.axes.Axes.tick_params`.
(12)                        When subplots have a shared axis that has units, calling
(12)                        `.Axis.set_units` will update each axis with the new units.
(12)                        Note that it is not possible to unshare axes.

(4)                 def legend(self, *args, **kwargs):
(8)                     """
(8)                     Place a legend on the figure.
(8)                     Call signatures::
(12)                        legend()
(12)                        legend(handles, labels)
(12)                        legend(handles=handles)
(12)                        legend(labels)
(8)                     The call signatures correspond to the following different ways to use
(8)                     this method:
(8)                     **1. Automatic detection of elements to be shown in the legend**
(8)                     The elements to be added to the legend are automatically determined,
(8)                     when you do not pass in any extra arguments.
(8)                     In this case, the labels are taken from the artist. You can specify
(8)                     them either at artist creation or by calling the
(8)                     :meth:`~.Artist.set_label` method on the artist::
(12)                        ax.plot([1, 2, 3], label='Inline label')
(12)                        fig.legend()
(8)                     or::
(12)                        line, = ax.plot([1, 2, 3])
(12)                        line.set_label('Label via method')
(12)                        fig.legend()
(8)                     Specific lines can be excluded from the automatic legend element
(8)                     selection by defining a label starting with an underscore.
(8)                     This is default for all artists, so calling `.Figure.legend` without
(8)                     any arguments and without setting the labels manually will result in
(8)                     no legend being drawn.
(8)                     **2. Explicitly listing the artists and labels in the legend**
(8)                     For full control of which artists have a legend entry, it is possible
(8)                     to pass an iterable of legend artists followed by an iterable of
(8)                     legend labels respectively::
(12)                        fig.legend([line1, line2, line3], ['label1', 'label2', 'label3'])
(8)                     **3. Explicitly listing the artists in the legend**
(8)                     This is similar to 2, but the labels are taken from the artists'
(8)                     label properties. Example::
(12)                        line1, = ax1.plot([1, 2, 3], label='label1')
(12)                        line2, = ax2.plot([1, 2, 3], label='label2')
(12)                        fig.legend(handles=[line1, line2])
(8)                     **4. Labeling existing plot elements**
(8)                     .. admonition:: Discouraged
(12)                        This call signature is discouraged, because the relation between
```

```
(12)                        plot elements and labels is only implicit by their order and can
(12)                        easily be mixed up.
(8)                     To make a legend for all artists on all Axes, call this function with
(8)                     an iterable of strings, one for each legend item. For example::
(12)                        fig, (ax1, ax2) = plt.subplots(1, 2)
(12)                        ax1.plot([1, 3, 5], color='blue')
(12)                        ax2.plot([2, 4, 6], color='red')
(12)                        fig.legend(['the blues', 'the reds'])
(8)                     Parameters
(8)                     ----------
(8)                     handles : list of `.Artist`, optional
(12)                        A list of Artists (lines, patches) to be added to the legend.
(12)                        Use this together with *labels*, if you need full control on what
(12)                        is shown in the legend and the automatic mechanism described above
(12)                        is not sufficient.

894: (8)                     """
895: (8)                     Add a colorbar to a plot.
896: (8)                     Parameters
897: (8)                     ----------
898: (8)                     mappable
899: (12)                        The `matplotlib.cm.ScalarMappable` (i.e., `.AxesImage`,
900: (12)                        `.ContourSet`, etc.) described by this colorbar.  This argument is
901: (12)                        mandatory for the `.Figure.colorbar` method but optional for the
902: (12)                        `.pyplot.colorbar` function, which sets the default to the current
903: (12)                        image.
904: (12)                        Note that one can create a `.ScalarMappable` "on-the-fly" to
905: (12)                        generate colorbars not attached to a previously drawn artist, e.g.
906: (12)                        ::
907: (16)                            fig.colorbar(cm.ScalarMappable(norm=norm, cmap=cmap), ax=ax)

909: (12)                        Axes into which the colorbar will be drawn.  If `None`, then a new
910: (12)                        Axes is created and the space for it will be stolen from the
Axes(s)
911: (12)                        specified in *ax*.
912: (8)                     ax : `~matplotlib.axes.Axes` or iterable or `numpy.ndarray` of Axes,
optional
913: (12)                        The one or more parent Axes from which space for a new colorbar
Axes
914: (12)                        will be stolen. This parameter is only used if *cax* is not set.
915: (12)                        Defaults to the Axes that contains the mappable used to create the
916: (12)                        colorbar.
917: (8)                     use_gridspec : bool, optional
918: (12)                        If *cax* is ``None``, a new *cax* is created as an instance of
919: (12)                        Axes.  If *ax* is positioned with a subplotspec and *use_gridspec*
920: (12)                        is ``True``, then *cax* is also positioned with a subplotspec.
921: (8)                     Returns
922: (8)                     -------

924: (8)                     Other Parameters
925: (8)                     ----------------
926: (8)                     %(_make_axes_kw_doc)s
927: (8)                     %(_colormap_kw_doc)s
928: (8)                     Notes
929: (8)                     -----
930: (8)                     If *mappable* is a `~.contour.ContourSet`, its *extend* kwarg is
931: (8)                     included automatically.
932: (8)                     The *shrink* kwarg provides a simple way to scale the colorbar with
933: (8)                     respect to the Axes. Note that if *cax* is specified, it determines
the
934: (8)                     size of the colorbar, and *shrink* and *aspect* are ignored.
935: (8)                     For more precise control, you can manually specify the positions of
the
936: (8)                     axes objects in which the mappable and the colorbar are drawn.  In
```

```
this
937: (8)                    case, do not use any of the Axes properties kwargs.
938: (8)                    It is known that some vector graphics viewers (svg and pdf) render
939: (8)                    white gaps between segments of the colorbar.  This is due to bugs in
940: (8)                    the viewers, not Matplotlib.  As a workaround, the colorbar can be
941: (8)                    rendered with overlapping segments::
942: (12)                       cbar = colorbar()
943: (12)                       cbar.solids.set_edgecolor("face")
944: (12)                       draw()
945: (8)                    However, this has negative consequences in other circumstances, e.g.
946: (8)                    with semi-transparent images (alpha < 1) and colorbar extensions;
947: (8)                    therefore, this workaround is not used by default (see issue #1188).
948: (8)                    """

(8)                 Add a set of subfigures to this figure or subfigure.
(8)                 A subfigure has the same artist methods as a figure, and is logically
(8)                 the same as a figure, but cannot print itself.
(8)                 See :doc:`/gallery/subplots_axes_and_figures/subfigures`.
(8)                 .. note::
(12)                    The *subfigure* concept is new in v3.4, and the API is still
provisional.
(8)                 Parameters
(8)                 ----------
(8)                 nrows, ncols : int, default: 1
(12)                    Number of rows/columns of the subfigure grid.
(8)                 squeeze : bool, default: True
(12)                    If True, extra dimensions are squeezed out from the returned
(12)                    array of subfigures.
(8)                 wspace, hspace : float, default: None
(12)                    The amount of width/height reserved for space between subfigures,
(12)                    expressed as a fraction of the average subfigure width/height.
(12)                    If not given, the values will be inferred from rcParams if using
(12)                    constrained layout (see `~.ConstrainedLayoutEngine`), or zero if
(12)                    not using a layout engine.
(8)                 width_ratios : array-like of length *ncols*, optional
(12)                    Defines the relative widths of the columns. Each column gets a
(12)                    relative width of ``width_ratios[i] / sum(width_ratios)``.
(12)                    If not given, all columns will have the same width.
(8)                 height_ratios : array-like of length *nrows*, optional
(12)                    Defines the relative heights of the rows. Each row gets a
(12)                    relative height of ``height_ratios[i] / sum(height_ratios)``.
(12)                    If not given, all rows will have the same height.

(8)                     Build a layout of Axes based on ASCII art or nested lists.
(8)                     This is a helper function to build complex GridSpec layouts visually.
(8)                     See :ref:`mosaic`
(8)                     for an example and full API documentation
(8)                     Parameters
(8)                     ----------
(8)                     mosaic : list of list of {hashable or nested} or str
(12)                        A visual layout of how you want your Axes to be arranged
(12)                        labeled as strings.  For example ::
(15)                           x = [['A panel', 'A panel', 'edge'],
(20)                                ['C panel', '.',       'edge']]
(12)                        produces 4 Axes:
(12)                        - 'A panel' which is 1 row high and spans the first two columns
(12)                        - 'edge' which is 2 rows high and is on the right edge
(12)                        - 'C panel' which in 1 row and 1 column wide in the bottom left
(12)                        - a blank space 1 row and 1 column wide in the bottom center
(12)                        Any of the entries in the layout can be a list of lists
(12)                        of the same form to create nested layouts.
(12)                        If input is a str, then it can either be a multi-line string of
(12)                        the form ::
```

```
1479: (14)                        '''
1480: (14)                        AAE
1481: (14)                        C.E
1482: (14)                        '''
1483: (12)                    where each character is a column and each line is a row. Or it
1484: (12)                    can be a single-line string where rows are separated by ``;``::
1485: (14)                        'AB;CC'
1486: (12)                    The string notation allows only single character Axes labels and
1487: (12)                    does not support nesting but is very terse.
1488: (12)                    The Axes identifiers may be `str` or a non-iterable hashable
1489: (12)                    object (e.g. `tuple` s may not be used).
1490: (8)                 sharex, sharey : bool, default: False
1491: (12)                    If True, the x-axis (*sharex*) or y-axis (*sharey*) will be shared
1492: (12)                    among all subplots.  In that case, tick label visibility and axis
1493: (12)                    units behave as for `subplots`.  If False, each subplot's x- or
1494: (12)                    y-axis will be independent.
1495: (8)                 width_ratios : array-like of length *ncols*, optional
1496: (12)                    Defines the relative widths of the columns. Each column gets a
1497: (12)                    relative width of ``width_ratios[i] / sum(width_ratios)``.
1498: (12)                    If not given, all columns will have the same width.  Equivalent
1499: (12)                    to ``gridspec_kw={'width_ratios': [...]}``. In the case of nested
1500: (12)                    layouts, this argument applies only to the outer layout.
1501: (8)                 height_ratios : array-like of length *nrows*, optional
1502: (12)                    Defines the relative heights of the rows. Each row gets a
1503: (12)                    relative height of ``height_ratios[i] / sum(height_ratios)``.
1504: (12)                    If not given, all rows will have the same height. Equivalent
1505: (12)                    to ``gridspec_kw={'height_ratios': [...]}``. In the case of nested
1506: (12)                    layouts, this argument applies only to the outer layout.
1507: (8)                 subplot_kw : dict, optional
1508: (12)                    Dictionary with keywords passed to the `.Figure.add_subplot` call
1509: (12)                    used to create each subplot.  These values may be overridden by
1510: (12)                    values in *per_subplot_kw*.
1511: (8)                 per_subplot_kw : dict, optional
1512: (12)                    A dictionary mapping the Axes identifiers or tuples of identifiers
1513: (12)                    to a dictionary of keyword arguments to be passed to the
1514: (12)                    `.Figure.add_subplot` call used to create each subplot.  The
values
1515: (12)                    in these dictionaries have precedence over the values in
1516: (12)                    *subplot_kw*.
1517: (12)                    If *mosaic* is a string, and thus all keys are single characters,
1518: (12)                    it is possible to use a single string instead of a tuple as keys;
1519: (12)                    i.e. ``"AB"`` is equivalent to ``("A", "B")``.
1520: (12)                    .. versionadded:: 3.7
1521: (8)                 gridspec_kw : dict, optional
1522: (12)                    Dictionary with keywords passed to the `.GridSpec` constructor
used
1523: (12)                    to create the grid the subplots are placed on. In the case of
1524: (12)                    nested layouts, this argument applies only to the outer layout.
1525: (12)                    For more complex layouts, users should use `.Figure.subfigures`
1526: (12)                    to create the nesting.
1527: (8)                 empty_sentinel : object, optional
1528: (12)                    Entry in the layout to mean "leave this space empty".  Defaults
1529: (12)                    to ``'.'``. Note, if *layout* is a string, it is processed via
1530: (12)                    `inspect.cleandoc` to remove leading white space, which may
1531: (12)                    interfere with using white-space as the empty sentinel.
1532: (8)                 Returns
1533: (8)                 -------
1534: (8)                 dict[label, Axes]
1535: (11)                   A dictionary mapping the labels to the Axes objects.  The order of
1536: (11)                   the Axes is left-to-right and top-to-bottom of their position in
the
1537: (11)                   total layout.

(4)                 """
(4)                 Logical figure that can be placed inside a figure.
(4)                 See :ref:`figure-api-subfigure` for an index of methods on this class.
(4)                 Typically instantiated using `.Figure.add_subfigure` or
(4)                 `.SubFigure.add_subfigure`, or `.SubFigure.subfigures`.  A subfigure has
(4)                 the same methods as a figure except for those particularly tied to the
size
(4)                 or dpi of the figure, and is confined to a prescribed region of the
figure.
(4)                 For example the following puts two subfigures side-by-side::
(8)                     fig = plt.figure()
(8)                     sfigs = fig.subfigures(1, 2)
(8)                     axsL = sfigs[0].subplots(1, 2)
(8)                     axsR = sfigs[1].subplots(2, 1)
(4)                 See :doc:`/gallery/subplots_axes_and_figures/subfigures`
(4)                 .. note::
(8)                     The *subfigure* concept is new in v3.4, and the API is still
provisional.
(4)                 """

(12)                        Figure dimension ``(width, height)`` in inches.
(8)                     dpi : float, default: :rc:`figure.dpi`
(12)                        Dots per inch.
(8)                     facecolor : default: :rc:`figure.facecolor`
(12)                        The figure patch facecolor.
(8)                     edgecolor : default: :rc:`figure.edgecolor`
(12)                        The figure patch edge color.
(8)                     linewidth : float
(12)                        The linewidth of the frame (i.e. the edge linewidth of the figure
(12)                        patch).
(8)                     frameon : bool, default: :rc:`figure.frameon`
(12)                        If ``False``, suppress drawing the figure background patch.
(8)                     subplotpars : `~matplotlib.gridspec.SubplotParams`
(12)                        Subplot parameters. If not given, the default subplot
(12)                        parameters :rc:`figure.subplot.*` are used.
(8)                     tight_layout : bool or dict, default: :rc:`figure.autolayout`
(12)                        Whether to use the tight layout mechanism. See
`.set_tight_layout`.
(12)                        .. admonition:: Discouraged
(16)                            The use of this parameter is discouraged. Please use
(16)                            ``layout='tight'`` instead for the common case of
(16)                            ``tight_layout=True`` and use `.set_tight_layout` otherwise.
(8)                     constrained_layout : bool, default:
:rc:`figure.constrained_layout.use`
(12)                        This is equal to ``layout='constrained'``.
(12)                        .. admonition:: Discouraged
(16)                            The use of this parameter is discouraged. Please use
(16)                            ``layout='constrained'`` instead.
(8)                     layout : {'constrained', 'compressed', 'tight', 'none',
`.LayoutEngine`, \
(0)             None}, default: None
(12)                        The layout mechanism for positioning of plot elements to avoid
(12)                        overlapping Axes decorations (labels, ticks, etc). Note that
(12)                        layout managers can have significant performance penalties.
(12)                        - 'constrained': The constrained layout solver adjusts Axes sizes
(14)                          to avoid overlapping Axes decorations.  Can handle complex plot
(14)                          layouts and colorbars, and is thus recommended.
(14)                          See :ref:`constrainedlayout_guide` for examples.
(12)                        - 'compressed': uses the same algorithm as 'constrained', but
(14)                          removes extra space between fixed-aspect-ratio Axes.  Best for
(14)                          simple grids of Axes.
(12)                        - 'tight': Use the tight layout mechanism. This is a relatively
(14)                          simple algorithm that adjusts the subplot parameters so that
(14)                          decorations do not overlap.
(14)                          See :ref:`tight_layout_guide` for examples.
(12)                        - 'none': Do not use a layout engine.
(12)                        - A `.LayoutEngine` instance. Builtin layout classes are
```

```
(14)                        `.ConstrainedLayoutEngine` and `.TightLayoutEngine`, more easily
(14)                        accessible by 'constrained' and 'tight'.  Passing an instance
(14)                        allows third parties to provide their own layout engine.
(12)                    If not given, fall back to using the parameters *tight_layout* and
(12)                    *constrained_layout*, including their config defaults
(12)                    :rc:`figure.autolayout` and :rc:`figure.constrained_layout.use`.

(8)                     ----------
(8)                     X
(12)                        The image data. This is an array of one of the following shapes:
(12)                        - (M, N): an image with scalar data.  Color-mapping is controlled
(14)                          by *cmap*, *norm*, *vmin*, and *vmax*.
(12)                        - (M, N, 3): an image with RGB values (0-1 float or 0-255 int).
(12)                        - (M, N, 4): an image with RGBA values (0-1 float or 0-255 int),
(14)                          i.e. including transparency.
(8)                     xo, yo : int
(12)                        The *x*/*y* image offset in pixels.
(8)                     alpha : None or float
(12)                        The alpha blending value.
(8)                     %(cmap_doc)s
(12)                        This parameter is ignored if *X* is RGB(A).
(8)                     %(norm_doc)s
(12)                        This parameter is ignored if *X* is RGB(A).
(8)                     %(vmin_vmax_doc)s
(12)                        This parameter is ignored if *X* is RGB(A).
(8)                     origin : {'upper', 'lower'}, default: :rc:`image.origin`
(12)                        Indicates where the [0, 0] index of the array is in the upper left
(12)                        or lower left corner of the Axes.
(8)                     resize : bool
(12)                        If *True*, resize the figure to match the given image size.
(8)                     Returns
(8)                     -------
(8)                     `matplotlib.image.FigureImage`
(8)                     Other Parameters
(8)                     ----------------
(8)                     **kwargs
(12)                        Additional kwargs are `.Artist` kwargs passed on to
`.FigureImage`.
(8)                     Notes
(8)                     -----
(8)                     figimage complements the Axes image (`~matplotlib.axes.Axes.imshow`)
(8)                     which will be resampled to fit the current Axes.  If you want
(8)                     a resampled image to fill the entire figure, you can define an
(8)                     `~matplotlib.axes.Axes` with extent [0, 0, 1, 1].
(8)                     Examples
(8)                     --------
(8)                     ::

(8)         """Whenever the Axes state change, ``func(self)`` will be called."""
(8)         self._axobservers.connect("_axes_change_event", lambda arg: func(arg))
(4)     def savefig(self, fname, *, transparent=None, **kwargs):
(8)         """
(8)         Save the current figure as an image or vector graphic to a file.
(8)         Call signature::
(10)          savefig(fname, *, transparent=None, dpi='figure', format=None,
(18)                  metadata=None, bbox_inches=None, pad_inches=0.1,
(18)                  facecolor='auto', edgecolor='auto', backend=None,
(18)                  **kwargs
(17)                 )
(8)         The available output formats depend on the backend being used.
(8)         Parameters
(8)         ----------
(8)         fname : str or path-like or binary file-like
(12)            A path, or a Python file-like object, or
(12)            possibly some backend-dependent object such as
(12)            `matplotlib.backends.backend_pdf.PdfPages`.
(12)            If *format* is set, it determines the output format, and the file
(12)            is saved as *fname*.  Note that *fname* is used verbatim, and
there
(12)            is no attempt to make the extension, if any, of *fname* match
(12)            *format*, and no extension is appended.
(12)            If *format* is not set, then the format is inferred from the
```

```
(12)                        extension of *fname*, if there is one.  If *format* is not
(12)                        set and *fname* has no extension, then the file is saved with
(12)                        :rc:`savefig.format` and the appropriate extension is appended to
(12)                        *fname*.
(8)                     Other Parameters
(8)                     ----------------
(8)                     transparent : bool, default: :rc:`savefig.transparent`
(12)                        If *True*, the Axes patches will all be transparent; the
(12)                        Figure patch will also be transparent unless *facecolor*
(12)                        and/or *edgecolor* are specified via kwargs.
(12)                        If *False* has no effect and the color of the Axes and
(12)                        Figure patches are unchanged (unless the Figure patch
(12)                        is specified via the *facecolor* and/or *edgecolor* keyword
(12)                        arguments in which case those colors are used).
(12)                        The transparency of these patches will be restored to their
(12)                        original values upon exit of this function.
(12)                        This is useful, for example, for displaying
(12)                        a plot on top of a colored background on a web page.
(8)                     dpi : float or 'figure', default: :rc:`savefig.dpi`
(12)                        The resolution in dots per inch.  If 'figure', use the figure's
(12)                        dpi value.
(8)                     format : str
(12)                        The file format, e.g. 'png', 'pdf', 'svg', ... The behavior when
(12)                        this is unset is documented under *fname*.
(8)                     metadata : dict, optional
(12)                        Key/value pairs to store in the image metadata. The supported keys
(12)                        and defaults depend on the image format and backend:
(12)                        - 'png' with Agg backend: See the parameter ``metadata`` of
(14)                          `~.FigureCanvasAgg.print_png`.
(12)                        - 'pdf' with pdf backend: See the parameter ``metadata`` of
(14)                          `~.backend_pdf.PdfPages`.
(12)                        - 'svg' with svg backend: See the parameter ``metadata`` of
(14)                          `~.FigureCanvasSVG.print_svg`.
(12)                        - 'eps' and 'ps' with PS backend: Only 'Creator' is supported.
(12)                        Not supported for 'pgf', 'raw', and 'rgba' as those formats do not
support
(12)                        embedding metadata.
(12)                        Does not currently support 'jpg', 'tiff', or 'webp', but may
include
(12)                        embedding EXIF metadata in the future.
(8)                     bbox_inches : str or `.Bbox`, default: :rc:`savefig.bbox`
(12)                        Bounding box in inches: only the given portion of the figure is
(12)                        saved.  If 'tight', try to figure out the tight bbox of the
figure.
(8)                     pad_inches : float or 'layout', default: :rc:`savefig.pad_inches`
(12)                        Amount of padding in inches around the figure when bbox_inches is
(12)                        'tight'. If 'layout' use the padding from the constrained or
(12)                        compressed layout engine; ignored if one of those engines is not
in
(12)                        use.
(8)                     facecolor : :mpltype:`color` or 'auto', default:
:rc:`savefig.facecolor`
(12)                        The facecolor of the figure.  If 'auto', use the current figure
(12)                        facecolor.
(8)                     edgecolor : :mpltype:`color` or 'auto', default:
:rc:`savefig.edgecolor`
(12)                        The edgecolor of the figure.  If 'auto', use the current figure
(12)                        edgecolor.
(8)                     backend : str, optional
(12)                        Use a non-default backend to render the file, e.g. to render a
(12)                        png file with the "cairo" backend rather than the default "agg",
(12)                        or a pdf file with the "pgf" backend rather than the default
(12)                        "pdf".  Note that the default backend is normally sufficient.  See
(12)                        :ref:`the-builtin-backends` for a list of valid backends for each
(12)                        file format.  Custom backends can be referenced as "module://...".
(8)                     orientation : {'landscape', 'portrait'}
(12)                        Currently only supported by the postscript backend.
(8)                     papertype : str
(12)                        One of 'letter', 'legal', 'executive', 'ledger', 'a0' through
```

```
(12)                        'a10', 'b0' through 'b10'. Only supported for postscript
(12)                        output.
(8)                     bbox_extra_artists : list of `~matplotlib.artist.Artist`, optional
(12)                        A list of extra artists that will be considered when the
(12)                        tight bbox is calculated.
(8)                     pil_kwargs : dict, optional
(12)                        Additional keyword arguments that are passed to
(12)                        `PIL.Image.Image.save` when saving the figure.

(8)                     """
(8)                     Blocking call to interact with a figure.
(8)                     Wait until the user clicks *n* times on the figure, and return the
(8)                     coordinates of each click in a list.
(8)                     There are three possible interactions:
(8)                     - Add a point.
(8)                     - Remove the most recently added point.
(8)                     - Stop the interaction and return the points added so far.
(8)                     The actions are assigned to mouse buttons via the arguments
(8)                     *mouse_add*, *mouse_pop* and *mouse_stop*.
(8)                     Parameters
(8)                     ----------
(8)                     n : int, default: 1
(12)                        Number of mouse clicks to accumulate. If negative, accumulate
(12)                        clicks until the input is terminated manually.
(8)                     timeout : float, default: 30 seconds
(12)                        Number of seconds to wait before timing out. If zero or negative
(12)                        will never time out.
(8)                     show_clicks : bool, default: True
(12)                        If True, show a red cross at the location of each click.
(8)                     mouse_add : `.MouseButton` or None, default: `.MouseButton.LEFT`
(12)                        Mouse button used to add points.
(8)                     mouse_pop : `.MouseButton` or None, default: `.MouseButton.RIGHT`
```

```
            Mouse button used to remove the most recently added point.
        mouse_stop : `.MouseButton` or None, default: `.MouseButton.MIDDLE`
            Mouse button used to stop input.
        Returns
        -------
        list of tuples
            A list of the clicked (x, y) coordinates.
        Notes
        -----
        The keyboard can also be used to select points in case your mouse
        does not have one or more of the buttons.  The delete and backspace
        keys act like right-clicking (i.e., remove last point), the enter key
        terminates input and any other key (not already used by the window
        manager) selects a point.

(16)                        previous_engine, (TightLayoutEngine, PlaceHolderLayoutEngine)
(12)                    ):
(16)                        _api.warn_external('The figure layout has changed to tight')
(8)                 finally:
(12)                    self.set_layout_engine('none')
(0)         def figaspect(arg):
(4)             """
(4)             Calculate the width and height for a figure with a specified aspect ratio.
(4)             While the height is taken from :rc:`figure.figsize`, the width is
(4)             adjusted to match the desired aspect ratio. Additionally, it is ensured
(4)             that the width is in the range [4., 16.] and the height is in the range
(4)             [2., 16.]. If necessary, the default height is adjusted to ensure this.
(4)             Parameters
(4)             ----------
(4)             arg : float or 2D array
(8)                 If a float, this defines the aspect ratio (i.e. the ratio height /
(8)                 width).
(8)                 In case of an array the aspect ratio is number of rows / number of
(8)                 columns, so that the array could be fitted in the figure undistorted.
(4)             Returns
(4)             -------
(4)             width, height : float
(8)                 The figure size in inches.
(4)             Notes
(4)             -----
(4)             If you want to create an Axes within the figure, that still preserves the
(4)             aspect ratio, be sure to create it with equal width and height. See
(4)             examples below.
(4)             Thanks to Fernando Perez for this function.
(4)             Examples
(4)             --------
(4)             Make a figure twice as tall as it is wide::
(8)                 w, h = figaspect(2.)
(8)                 fig = Figure(figsize=(w, h))
(8)                 ax = fig.add_axes([0.1, 0.1, 0.8, 0.8])
(8)                 ax.imshow(A, **kwargs)
(4)             Make a figure with the proper aspect for an array::
(8)                 A = rand(5, 3)
(8)                 w, h = figaspect(A)
(8)                 fig = Figure(figsize=(w, h))
(8)                 ax = fig.add_axes([0.1, 0.1, 0.8, 0.8])
(8)                 ax.imshow(A, **kwargs)
(4)             """

File 39 - font_manager.py:

```
1: (0)              """
2: (0)              A module for finding, managing, and using fonts across platforms.
3: (0)              This module provides a single `FontManager` instance, ``fontManager``, that
can
4: (0)              be shared across backends and platforms.  The `findfont`
5: (0)              function returns the best TrueType (TTF) font file in the local or
6: (0)              system font path that matches the specified `FontProperties`
7: (0)              instance.  The `FontManager` also handles Adobe Font Metrics
8: (0)              (AFM) font files for use by the PostScript backend.
9: (0)              The `FontManager.addfont` function adds a custom font from a file without
10: (0)             installing it into your operating system.
11: (0)             The design is based on the `W3C Cascading Style Sheet, Level 1 (CSS1)
12: (0)             font specification <http://www.w3.org/TR/1998/REC-CSS2-19980512/>`_.
13: (0)             Future versions may implement the Level 2 or 2.1 specifications.
14: (0)             """

(4)             else:
(8)                 stretch = 'normal'
(4)             size = 'scalable'
(4)             return FontEntry(fontpath, name, style, variant, weight, stretch, size)
(0)         class FontProperties:
(4)             """
(4)             A class for storing and manipulating font properties.
(4)             The font properties are the six properties described in the
(4)             `W3C Cascading Style Sheet, Level 1
(4)             <http://www.w3.org/TR/1998/REC-CSS2-19980512/>`_ font
(4)             specification and *math_fontfamily* for math fonts:
(4)             - family: A list of font names in decreasing order of priority.
(6)               The items may include a generic font family name, either 'sans-serif',
(6)               'serif', 'cursive', 'fantasy', or 'monospace'.  In that case, the actual
(6)               font to be used will be looked up from the associated rcParam during the
(6)               search process in `.findfont`. Default: :rc:`font.family`
(4)             - style: Either 'normal', 'italic' or 'oblique'.
(6)               Default: :rc:`font.style`
(4)             - variant: Either 'normal' or 'small-caps'.
(6)               Default: :rc:`font.variant`
(4)             - stretch: A numeric value in the range 0-1000 or one of
(6)               'ultra-condensed', 'extra-condensed', 'condensed',
(6)               'semi-condensed', 'normal', 'semi-expanded', 'expanded',
(6)               'extra-expanded' or 'ultra-expanded'. Default: :rc:`font.stretch`
(4)             - weight: A numeric value in the range 0-1000 or one of
(6)               'ultralight', 'light', 'normal', 'regular', 'book', 'medium',
(6)               'roman', 'semibold', 'demibold', 'demi', 'bold', 'heavy',
(6)               'extra bold', 'black'. Default: :rc:`font.weight`
(4)             - size: Either a relative value of 'xx-small', 'x-small',
(6)               'small', 'medium', 'large', 'x-large', 'xx-large' or an
(6)               absolute font size, e.g., 10. Default: :rc:`font.size`
(4)             - math_fontfamily: The family of fonts used to render math text.
(6)               Supported values are: 'dejavusans', 'dejavuserif', 'cm',
(6)               'stix', 'stixsans' and 'custom'. Default: :rc:`mathtext.fontset`
(4)             Alternatively, a font may be specified using the absolute path to a font
(4)             file, by using the *fname* kwarg.  However, in this case, it is typically
(4)             simpler to just pass the path (as a `pathlib.Path`, not a `str`) to the
(4)             *font* kwarg of the `.Text` object.
(4)             The preferred usage of font sizes is to use the relative values,
(4)             e.g.,  'large', instead of absolute font sizes, e.g., 12.  This
(4)             approach allows all text sizes to be made larger or smaller based
(4)             on the font manager's default font size.
(4)             This class will also accept a fontconfig_ pattern_, if it is the only
(4)             argument provided.  This support does not depend on fontconfig; we are
(4)             merely borrowing its pattern syntax for use here.
(4)             .. _fontconfig: https://www.freedesktop.org/wiki/Software/fontconfig/
(4)             .. _pattern:
(7)                https://www.freedesktop.org/software/fontconfig/fontconfig-user.html
(4)             Note that Matplotlib's internal font manager and fontconfig use a
(4)             different algorithm to lookup fonts, so the results of the same pattern
(4)             may be different in Matplotlib than in other applications that use
(4)             fontconfig.

(8)                 ----------
(8)                 prop : str or `~matplotlib.font_manager.FontProperties`
(12)                    The font properties to search for. This can be either a
(12)                    `.FontProperties` object or a string defining a
(12)                    `fontconfig patterns`_.
(8)                 fontext : {'ttf', 'afm'}, default: 'ttf'
(12)                    The extension of the font file:
(12)                    - 'ttf': TrueType and OpenType fonts (.ttf, .ttc, .otf)
(12)                    - 'afm': Adobe Font Metrics (.afm)
(8)                 directory : str, optional
(12)                    If given, only search this directory and its subdirectories.
(8)                 fallback_to_default : bool
(12)                    If True, will fall back to the default font family (usually
(12)                    "DejaVu Sans" or "Helvetica") if the first lookup hard-fails.
(8)                 rebuild_if_missing : bool
(12)                    Whether to rebuild the font cache and search again if the first
(12)                    match appears to point to a nonexisting font (i.e., the font cache
(12)                    contains outdated entries).
(8)                 Returns
(8)                 -------
(8)                 str
(12)                    The filename of the best matching font.
(8)                 Notes
(8)                 -----
(8)                 This performs a nearest neighbor search.  Each font is given a
(8)                 similarity score to the target font properties.  The first font with
```

```
(8)                     the highest score is returned.  If no matches below a certain
(8)                     threshold are found, the default font (usually DejaVu Sans) is
(8)                     returned.
(8)                     The result is cached, so subsequent lookups don't have to
(8)                     perform the O(n) nearest neighbor search.
(8)                     See the `W3C Cascading Style Sheet, Level 1
(8)                     <http://www.w3.org/TR/1998/REC-CSS2-19980512/>`_ documentation

274: (8)                     Normalize, rescale, and colormap the image *A* from the given
```

```
*in_bbox*
                    (in data space), to the given *out_bbox* (in pixel space) clipped to
                    the given *clip_bbox* (also in pixel space), and magnified by the
                    *magnification* factor.
                    *A* may be a greyscale image (M, N) with a dtype of `~numpy.float32`,
                    `~numpy.float64`, `~numpy.float128`, `~numpy.uint16` or
`~numpy.uint8`,
                    or an (M, N, 4) RGBA image with a dtype of `~numpy.float32`,
                    `~numpy.float64`, `~numpy.float128`, or `~numpy.uint8`.
                    If *unsampled* is True, the image will not be scaled, but an
                    appropriate affine transformation will be returned instead.
                    If *round_to_pixel_border* is True, the output image size will be
                    rounded to the nearest pixel boundary.  This makes the images align
                    correctly with the Axes.  It should not be used if exact scaling is
                    needed, such as for `FigureImage`.
                    Returns
                    -------
                    image : (M, N, 4) `numpy.uint8` array
                        The RGBA image, resampled unless *unsampled* is True.

(4)                 An image attached to an Axes.
(4)                 Parameters
(4)                 ----------
(4)                 ax : `~matplotlib.axes.Axes`
(8)                     The Axes the image will belong to.
(4)                 cmap : str or `~matplotlib.colors.Colormap`, default: :rc:`image.cmap`
(8)                     The Colormap instance or registered colormap name used to map scalar
(8)                     data to colors.
(4)                 norm : str or `~matplotlib.colors.Normalize`
(8)                     Maps luminance to 0-1.
(4)                 interpolation : str, default: :rc:`image.interpolation`
(8)                     Supported values are 'none', 'antialiased', 'nearest', 'bilinear',
(8)                     'bicubic', 'spline16', 'spline36', 'hanning', 'hamming', 'hermite',
(8)                     'kaiser', 'quadric', 'catrom', 'gaussian', 'bessel', 'mitchell',
(8)                     'sinc', 'lanczos', 'blackman'.
(4)                 interpolation_stage : {'data', 'rgba'}, default: 'data'
(8)                     If 'data', interpolation
(8)                     is carried out on the data provided by the user.  If 'rgba', the
(8)                     interpolation is carried out after the colormapping has been
```

```
(8)                 applied (visual interpolation).
(4)             origin : {'upper', 'lower'}, default: :rc:`image.origin`
(8)                 Place the [0, 0] index of the array in the upper left or lower left
(8)                 corner of the Axes. The convention 'upper' is typically used for
(8)                 matrices and images.
(4)             extent : tuple, optional
(8)                 The data axes (left, right, bottom, top) for making image plots
(8)                 registered with data plots.  Default is to label the pixel
(8)                 centers with the zero-based row and column indices.
(4)             filternorm : bool, default: True
(8)                 A parameter for the antigrain image resize filter
(8)                 (see the antigrain documentation).
(8)                 If filternorm is set, the filter normalizes integer values and
corrects
(8)                 the rounding errors. It doesn't do anything with the source floating
(8)                 point values, it corrects only integers according to the rule of 1.0
(8)                 which means that any sum of pixel weights must be equal to 1.0. So,
(8)                 the filter function must produce a graph of the proper shape.
(4)             filterrad : float > 0, default: 4
(8)                 The filter radius for filters that have a radius parameter, i.e. when
(8)                 interpolation is one of: 'sinc', 'lanczos' or 'blackman'.
(4)             resample : bool, default: False
(8)                 When True, use a full resampling method. When False, only resample
when
(8)                 the output image is larger than the input image.

(7)                image I/O library (such as pillow, tifffile, or imageio) directly.
(4)             Parameters
(4)             ----------
(4)             fname : str or path-like or file-like
(8)                 A path or a file-like object to store the image in.
(8)                 If *format* is not set, then the output format is inferred from the
(8)                 extension of *fname*, if any, and from :rc:`savefig.format` otherwise.
(8)                 If *format* is set, it determines the output format.
(4)             arr : array-like
(8)                 The image data. The shape can be one of
(8)                 MxN (luminance), MxNx3 (RGB) or MxNx4 (RGBA).
(4)             vmin, vmax : float, optional
(8)                 *vmin* and *vmax* set the color scaling for the image by fixing the
(8)                 values that map to the colormap color limits. If either *vmin*
(8)                 or *vmax* is None, that limit is determined from the *arr*
(8)                 min/max value.
(4)             cmap : str or `~matplotlib.colors.Colormap`, default: :rc:`image.cmap`
(8)                 A Colormap instance or registered colormap name. The colormap
(8)                 maps scalar data to colors. It is ignored for RGB(A) data.
(4)             format : str, optional
(8)                 The file format, e.g. 'png', 'pdf', 'svg', ...  The behavior when this
(8)                 is unset is documented under *fname*.
(4)             origin : {'upper', 'lower'}, default: :rc:`image.origin`
(8)                 Indicates whether the ``(0, 0)`` index of the array is in the upper
(8)                 left or lower left corner of the Axes.
(4)             dpi : float
(8)                 The DPI to store in the metadata of the file.  This does not affect
the
(8)                 resolution of the output image.  Depending on file format, this may be
(8)                 rounded to the nearest integer.
(4)             metadata : dict, optional
(8)                 Metadata in the image file.  The supported keys depend on the output
(8)                 format, see the documentation of the respective backends for more
(8)                 information.
(8)                 Currently only supported for "png", "pdf", "ps", "eps", and "svg".
(4)             pil_kwargs : dict, optional
(8)                 Keyword arguments passed to `PIL.Image.Image.save`.  If the 'pnginfo'
(8)                 key is present, it completely overrides *metadata*, including the
(8)                 default 'Software' key.

File 43 - layout_engine.py:

```
1: (0)              """
2: (0)              Classes to layout elements in a `.Figure`.
3: (0)              Figures have a ``layout_engine`` property that holds a subclass of
4: (0)              `~.LayoutEngine` defined here (or *None* for no layout).  At draw time
5: (0)              ``figure.get_layout_engine().execute()`` is called, the goal of which is
6: (0)              usually to rearrange Axes on the figure to produce a pleasing layout. This is
7: (0)              like a ``draw`` callback but with two differences.  First, when printing we
8: (0)              disable the layout engine for the final draw. Second, it is useful to know the
9: (0)              layout engine while the figure is being created.  In particular, colorbars are
10: (0)             made differently with different layout engines (for historical reasons).
11: (0)             Matplotlib supplies two layout engines, `.TightLayoutEngine` and
12: (0)             `.ConstrainedLayoutEngine`.  Third parties can create their own layout engine
13: (0)             by subclassing `.LayoutEngine`.
14: (0)             """
15: (0)             from contextlib import nullcontext
16: (0)             import matplotlib as mpl
17: (0)             from matplotlib._constrained_layout import do_constrained_layout
18: (0)             from matplotlib._tight_layout import (get_subplotspec_list,
19: (38)                                                  get_tight_layout_figure)
20: (0)             class LayoutEngine:
21: (4)                 """
22: (4)                 Base class for Matplotlib layout engines.
23: (4)                 A layout engine can be passed to a figure at instantiation or at any time
24: (4)                 with `~.figure.Figure.set_layout_engine`.  Once attached to a figure, the
25: (4)                 layout engine ``execute`` function is called at draw time by
26: (4)                 `~.figure.Figure.draw`, providing a special draw-time hook.
27: (4)                 .. note::
28: (7)                    However, note that layout engines affect the creation of colorbars, so
29: (7)                    `~.figure.Figure.set_layout_engine` should be called before any
30: (7)                    colorbars are created.
31: (4)                 Currently, there are two properties of `LayoutEngine` classes that are
32: (4)                 consulted while manipulating the figure:
33: (4)                 - ``engine.colorbar_gridspec`` tells `.Figure.colorbar` whether to make
the
34: (7)                    axes using the gridspec method (see `.colorbar.make_axes_gridspec`) or

File 44 - legend_handler.py:

```
1: (0)              """
2: (0)              Default legend handlers.
3: (0)              .. important::
4: (4)                  This is a low-level legend API, which most end users do not need.
5: (4)                  We recommend that you are familiar with the :ref:`legend guide
6: (4)                  <legend_guide>` before reading this documentation.
7: (0)              Legend handlers are expected to be a callable object with a following
8: (0)              signature::
9: (4)                  legend_handler(legend, orig_handle, fontsize, handlebox)
10: (0)             Where *legend* is the legend itself, *orig_handle* is the original
11: (0)             plot, *fontsize* is the fontsize in pixels, and *handlebox* is an
12: (0)             `.OffsetBox` instance. Within the call, you should create relevant
13: (0)             artists (using relevant properties from the *legend* and/or
14: (0)             *orig_handle*) and add them into the *handlebox*. The artists need to
15: (0)             be scaled according to the *fontsize* (note that the size is in pixels,
16: (0)             i.e., this is dpi-scaled value).
17: (0)             This module includes definition of several legend handler classes
18: (0)             derived from the base class (HandlerBase) with the following method::
19: (4)                 def legend_artist(self, legend, orig_handle, fontsize, handlebox)
20: (0)             """

----------------------------------------

File 45 - legend.py:

1: (0)              """
2: (0)              The legend module defines the Legend class, which is responsible for
3: (0)              drawing legends associated with Axes and/or figures.
4: (0)              .. important::
5: (4)                  It is unlikely that you would ever create a Legend instance manually.
6: (4)                  Most users would normally create a legend via the `~.Axes.legend`
7: (4)                  function. For more details on legends there is also a :ref:`legend guide
8: (4)                  <legend_guide>`.
9: (0)              The `Legend` class is a container of legend handles and legend texts.
10: (0)             The legend handler map specifies how to create legend handles from artists
11: (0)             (lines, patches, etc.) in the Axes or figures. Default legend handlers are
12: (0)             defined in the :mod:`~matplotlib.legend_handler` module. While not all artist
13: (0)             types are covered by the default legend handlers, custom legend handlers can
be
14: (0)             defined to support arbitrary objects.
15: (0)             See the :ref`<legend_guide>` for more
16: (0)             information.
17: (0)             """

79: (0)             bbox_to_anchor : `.BboxBase`, 2-tuple, or 4-tuple of floats
80: (4)                 Box that is used to position the legend in conjunction with *loc*.
81: (4)                 Defaults to `axes.bbox` (if called as a method to `.Axes.legend`) or
82: (4)                 `figure.bbox` (if `.Figure.legend`).  This argument allows arbitrary
83: (4)                 placement of the legend.
84: (4)                 Bbox coordinates are interpreted in the coordinate system given by
85: (4)                 *bbox_transform*, with the default transform
86: (4)                 Axes or Figure coordinates, depending on which ``legend`` is called.
87: (4)                 If a 4-tuple or `.BboxBase` is given, then it specifies the bbox
88: (4)                 ``(x, y, width, height)`` that the legend is placed in.
89: (4)                 To put the legend in the best location in the bottom right
90: (4)                 quadrant of the Axes (or figure)::
91: (8)                     loc='best', bbox_to_anchor=(0.5, 0., 0.5, 0.5)
92: (4)                 A 2-tuple ``(x, y)`` places the corner of the legend specified by *loc* at
93: (4)                 x, y.  For example, to put the legend's upper right-hand corner in the
94: (4)                 center of the Axes (or figure) the following keywords can be used::
95: (8)                     loc='upper right', bbox_to_anchor=(0.5, 0.5)
96: (0)             ncols : int, default: 1
97: (4)                 The number of columns that the legend has.
98: (4)                 For backward compatibility, the spelling *ncol* is also supported
99: (4)                 but it is discouraged. If both are given, *ncols* takes precedence.
100: (0)            prop : None or `~matplotlib.font_manager.FontProperties` or dict
101: (4)                The font properties of the legend. If None (default), the current
102: (4)                :data:`matplotlib.rcParams` will be used.
103: (0)            fontsize : int or {'xx-small', 'x-small', 'small', 'medium', 'large', \
104: (0)            'x-large', 'xx-large'}
105: (4)                The font size of the legend. If the value is numeric the size will be the
106: (4)                absolute font size in points. String values are relative to the current
107: (4)                default font size. This argument is only used if *prop* is not specified.
108: (0)            labelcolor : str or list, default: :rc:`legend.labelcolor`
109: (4)                The color of the text in the legend. Either a valid color string
110: (4)                (for example, 'red'), or a list of color strings. The labelcolor can
111: (4)                also be made to match the color of the line or marker using 'linecolor',
112: (4)                'markerfacecolor' (or 'mfc'), or 'markeredgecolor' (or 'mec').
113: (4)                Labelcolor can be set globally using :rc:`legend.labelcolor`. If None,
114: (4)                use :rc:`text.color`.
```

```
(0)             numpoints : int, default: :rc:`legend.numpoints`
(4)                 The number of marker points in the legend when creating a legend
(4)                 entry for a `.Line2D` (line).
(0)             scatterpoints : int, default: :rc:`legend.scatterpoints`
(4)                 The number of marker points in the legend when creating
(4)                 a legend entry for a `.PathCollection` (scatter plot).
(0)             scatteryoffsets : iterable of floats, default: ``[0.375, 0.5, 0.3125]``
(4)                 The vertical offset (relative to the font size) for the markers
(4)                 created for a scatter plot legend entry. 0.0 is at the base the
(4)                 legend text, and 1.0 is at the top. To draw all markers at the
(4)                 same height, set to ``[0.5]``.
(0)             markerscale : float, default: :rc:`legend.markerscale`
(4)                 The relative size of legend markers compared to the originally drawn ones.
(0)             markerfirst : bool, default: True
(4)                 If *True*, legend marker is placed to the left of the legend label.
(4)                 If *False*, legend marker is placed to the right of the legend label.
(0)             reverse : bool, default: False
(4)                 If *True*, the legend labels are displayed in reverse order from the
input.
(4)                 If *False*, the legend labels are displayed in the same order as the
input.
(4)                 .. versionadded:: 3.7
(0)             frameon : bool, default: :rc:`legend.frameon`
(4)                 Whether the legend should be drawn on a patch (frame).
(0)             fancybox : bool, default: :rc:`legend.fancybox`
(4)                 Whether round edges should be enabled around the `.FancyBboxPatch` which
(4)                 makes up the legend's background.
(0)             shadow : None, bool or dict, default: :rc:`legend.shadow`
(4)                 Whether to draw a shadow behind the legend.
(4)                 The shadow can be configured using `.Patch` keywords.
(4)                 Customization via :rc:`legend.shadow` is currently not supported.
(0)             framealpha : float, default: :rc:`legend.framealpha`
(4)                 The alpha transparency of the legend's background.
(4)                 If *shadow* is activated and *framealpha* is ``None``, the default value
is
(4)                 ignored.
(0)             facecolor : "inherit" or color, default: :rc:`legend.facecolor`
(4)                 The legend's background color.
(4)                 If ``"inherit"``, use :rc:`axes.facecolor`.
(0)             edgecolor : "inherit" or color, default: :rc:`legend.edgecolor`
(4)                 The legend's background patch edge color.
(4)                 If ``"inherit"``, use :rc:`axes.edgecolor`.
(0)             mode : {"expand", None}
(4)                 If *mode* is set to ``"expand"`` the legend will be horizontally
(4)                 expanded to fill the Axes area (or *bbox_to_anchor* if defines
(4)                 the legend's size).
(0)             bbox_transform : None or `~matplotlib.transforms.Transform`
(4)                 The transform for the bounding box (*bbox_to_anchor*). For a value
(4)                 of ``None`` (default) the Axes'
(4)                 :data:`~matplotlib.axes.Axes.transAxes` transform will be used.
(0)             title : str or None
(4)                 The legend's title. Default is no title (``None``).
(0)             title_fontproperties : None or `~matplotlib.font_manager.FontProperties` or
dict
(4)                 The font properties of the legend's title. If None (default), the
(4)                 *title_fontsize* argument will be used if present; if *title_fontsize* is
(4)                 also None, the current :rc:`legend.title_fontsize` will be used.
(0)             title_fontsize : int or {'xx-small', 'x-small', 'small', 'medium', 'large', \
(0)             'x-large', 'xx-large'}, default: :rc:`legend.title_fontsize`
(4)                 The font size of the legend's title.
(4)                 Note: This cannot be combined with *title_fontproperties*. If you want
(4)                 to set the fontsize alongside other font properties, use the *size*
(4)                 parameter in *title_fontproperties*.
(0)             alignment : {'center', 'left', 'right'}, default: 'center'
(4)                 The alignment of the legend title and the box of entries. The entries
(4)                 are aligned as a single block, so that markers always lined up.
(0)             borderpad : float, default: :rc:`legend.borderpad`
(4)                 The fractional whitespace inside the legend border, in font-size units.
(0)             labelspacing : float, default: :rc:`legend.labelspacing`
```

```
(4)                 The vertical space between the legend entries, in font-size units.
(0)             handlelength : float, default: :rc:`legend.handlelength`
(4)                 The length of the legend handles, in font-size units.
(0)             handleheight : float, default: :rc:`legend.handleheight`
(4)                 The height of the legend handles, in font-size units.
(0)             handletextpad : float, default: :rc:`legend.handletextpad`
(4)                 The pad between the legend handle and text, in font-size units.
(0)             borderaxespad : float, default: :rc:`legend.borderaxespad`
(4)                 The pad between the Axes and legend border, in font-size units.
(0)             columnspacing : float, default: :rc:`legend.columnspacing`
(4)                 The spacing between columns, in font-size units.
(0)             handler_map : dict or None
(4)                 The custom dictionary mapping instances or types to a legend
(4)                 handler. This *handler_map* updates the default handler map
(4)                 found at `matplotlib.legend.Legend.get_legend_handler_map`.
(0)             draggable : bool, default: False
(4)                 Whether the legend can be dragged with the mouse.
(0)             """
(0)             _loc_doc_base = """
(0)             loc : str or pair of floats, default: {default}
(4)                 The location of the legend.
(4)                 The strings ``'upper left'``, ``'upper right'``, ``'lower left'``,
(4)                 ``'lower right'`` place the legend at the corresponding corner of the
(4)                 {parent}.
(4)                 The strings ``'upper center'``, ``'lower center'``, ``'center left'``,
(4)                 ``'center right'`` place the legend at the center of the corresponding
edge
(4)                 of the {parent}.
(4)                 The string ``'center'`` places the legend at the center of the {parent}.
(0)             {best}
(4)                 The location can also be a 2-tuple giving the coordinates of the lower-
left
(4)                 corner of the legend in {parent} coordinates (in which case
*bbox_to_anchor*
(4)                 will be ignored).
(4)                 For back-compatibility, ``'center right'`` (but no other location) can
also
(4)                 be spelled ``'right'``, and each "string" location can also be given as a
(4)                 numeric value:
(4)                 ==================   =============
(4)                 Location String      Location Code
(4)                 ==================   =============
(4)                 'best' (Axes only)   0
(4)                 'upper right'        1
(4)                 'upper left'         2
(4)                 'lower left'         3
(4)                 'lower right'        4
(4)                 'right'              5

    Get the handles and labels from the calls to either ``figure.legend``
    or ``axes.legend``.
    The parser is a bit involved because we support::
        legend()
        legend(labels)
        legend(handles, labels)
        legend(labels=labels)
        legend(handles=handles)
        legend(handles=handles, labels=labels)
    The behavior for a mixture of positional and keyword handles and labels
    is undefined and issues a warning; it will be an error in the future.
    Parameters
    ----------
    axs : list of `.Axes`
        If handles are not given explicitly, the artists in these Axes are
        used as handles.
    *args : tuple
        Positional parameters passed to ``legend()``.
    handles
        The value of the keyword argument ``legend(handles=...)``, or *None*
        if that keyword argument was not used.
    labels
        The value of the keyword argument ``legend(labels=...)``, or *None*
        if that keyword argument was not used.
    **kwargs
        All other keyword arguments passed to ``legend()``.
    Returns
    -------
    handles : list of (`.Artist` or tuple of `.Artist`)
        The legend handles.
    labels : list of str
        The legend labels.
    kwargs : dict
        *kwargs* with keywords handles and labels removed.

        """
        Set the markevery property to subsample the plot when using markers.
        e.g., if ``every=5``, every 5-th marker will be plotted.
        Parameters
        ----------
        every : None or int or (int, int) or slice or list[int] or float or \
(float, float) or list[bool]
            Which markers to plot.
            - ``every=None``: every point will be plotted.
            - ``every=N``: every N-th marker will be plotted starting with
              marker 0.
            - ``every=(start, N)``: every N-th marker, starting at index
              *start*, will be plotted.
            - ``every=slice(start, end, N)``: every N-th marker, starting at
              index *start*, up to but not including index *end*, will be
              plotted.
            - ``every=[i, j, m, ...]``: only markers at the given indices
              will be plotted.
            - ``every=[True, False, True, ...]``: only positions that are True
              will be plotted. The list must have the same length as the data
              points.
            - ``every=0.1``, (i.e. a float): markers will be spaced at
              approximately equal visual distances along the line; the
distance
              along the line between markers is determined by multiplying the
              display-coordinate distance of the Axes bounding-box diagonal
              by the value of *every*.
            - ``every=(0.5, 0.1)`` (i.e. a length-2 tuple of float): similar
              to ``every=0.1`` but the first marker will be offset along the
              line by 0.5 multiplied by the
              display-coordinate-diagonal-distance along the line.
            For examples see
            :doc:`/gallery/lines_bars_and_markers/markevery_demo`.
        Notes
        -----
        Setting *markevery* will still only draw markers at actual data
points.
        While the float argument form aims for uniform visual spacing, it has
        to coerce from the ideal spacing to the nearest available data point.
        Depending on the number and distribution of data points, the result
        may still not look evenly spaced.
        When using a start offset to specify the first marker, the offset will
        be from the first data point which may be different from the first
        the visible data point if the plot is zoomed in.
        If zooming in on a plot when using float arguments then the actual
        data points that have markers will change because the distance between
        markers is always determined from the display-coordinates
        axes-bounding-box-diagonal regardless of the actual axes data limits.

        Set the drawstyle of the plot.
        The drawstyle determines how the points are connected.
        Parameters
        ----------
        drawstyle : {'default', 'steps', 'steps-pre', 'steps-mid', \
'steps-post'}, default: 'default'
            For 'default', the points are connected with straight lines.
            The steps variants connect the points with step-like lines,
            i.e. horizontal lines with vertical steps. They differ in the
            location of the step:
            - 'steps-pre': The step is at the beginning of the line segment,
              i.e. the line will be at the y-value of point to the right.
            - 'steps-mid': The step is halfway between the points.
            - 'steps-post: The step is at the end of the line segment,
              i.e. the line will be at the y-value of the point to the left.
            - 'steps' is equal to 'steps-pre' and is maintained for
              backward-compatibility.
            For examples see :doc:`/gallery/lines_bars_and_markers/step_demo`.

 50: (38)                                                  letter ``f``.
 51: (0)             ``verts``                             A list of (x, y) pairs used for Path
 52: (38)                                                  vertices. The center of the marker is
 53: (38)                                                  located at (0, 0) and the size is
 54: (38)                                                  normalized, such that the created path
 55: (38)                                                  is encapsulated inside the unit cell.
 56: (0)             ``path``                              A `~matplotlib.path.Path` instance.
 57: (0)             ``(numsides, 0, angle)``              A regular polygon with ``numsides``
 58: (38)                                                  sides, rotated by ``angle``.
 59: (0)             ``(numsides, 1, angle)``              A star-like symbol with ``numsides``
 60: (38)                                                  sides, rotated by ``angle``.
 61: (0)             ``(numsides, 2, angle)``              An asterisk with ``numsides`` sides,
 62: (38)                                                  rotated by ``angle``.
 63: (0)             ============================= ======
 ==========================================
 64: (0)             Note that special symbols can be defined via the
 65: (0)             :ref:`STIX math font <mathtext>`,
 66: (0)             e.g. ``"$\u266B$"``. For an overview over the STIX font symbols refer to the
 67: (0)             `STIX font table <http://www.stixfonts.org/allGlyphs.html>`_.
 68: (0)             Also see the :doc:`/gallery/text_labels_and_annotations/stix_fonts_demo`.
 69: (0)             Integer numbers from ``0`` to ``11`` create lines and triangles. Those are
 70: (0)             equally accessible via capitalized variables, like ``CARETDOWNBASE``.
 71: (0)             Hence the following are equivalent::
 72: (4)                 plt.plot([1, 2, 3], marker=11)
 73: (4)                 plt.plot([1, 2, 3], marker=matplotlib.markers.CARETDOWNBASE)
 74: (0)             Markers join and cap styles can be customized by creating a new instance of
 75: (0)             MarkerStyle.
 76: (0)             A MarkerStyle can also have a custom `~matplotlib.transforms.Transform`
 77: (0)             allowing it to be arbitrarily rotated or offset.

File 48 - mathtext.py:

```
1: (0)              r"""
2: (0)              A module for parsing a subset of the TeX math syntax and rendering it to a
3: (0)              Matplotlib backend.
```

```
4: (0)              For a tutorial of its usage, see :ref:`mathtext`.  This
5: (0)              document is primarily concerned with implementation details.
6: (0)              The module uses pyparsing_ to parse the TeX expression.
7: (0)              .. _pyparsing: https://pypi.org/project/pyparsing/
8: (0)              The Bakoma distribution of the TeX Computer Modern fonts, and STIX
9: (0)              fonts are supported.  There is experimental support for using
10: (0)             arbitrary fonts, but results may vary without proper tweaking and
11: (0)             metrics for those fonts.
12: (0)             """

(0)             pad_to : int, optional
(4)                 The number of points to which the data segment is padded when performing
(4)                 the FFT.  While not increasing the actual resolution of the spectrum (the
(4)                 minimum distance between resolvable peaks), this can give more points in
(4)                 the plot, allowing for more detail. This corresponds to the *n* parameter
(4)                 in the call to `~numpy.fft.fft`.  The default is None, which sets *pad_to*
(4)                 equal to the length of the input signal (i.e. no padding)."""",
(4)                 PSD="""\
(0)             pad_to : int, optional
(4)                 The number of points to which the data segment is padded when performing
(4)                 the FFT.  This can be different from *NFFT*, which specifies the number
(4)                 of data points used.  While not increasing the actual resolution of the
(4)                 spectrum (the minimum distance between resolvable peaks), this can give
(4)                 more points in the plot, allowing for more detail. This corresponds to
(4)                 the *n* parameter in the call to `~numpy.fft.fft`. The default is None,
(4)                 which sets *pad_to* equal to *NFFT*
(0)             NFFT : int, default: 256
(4)                 The number of data points used in each block for the FFT.  A power 2 is
(4)                 most efficient.  This should *NOT* be used to get zero padding, or the
(4)                 scaling of the result will be incorrect; use *pad_to* for this instead.
(0)             detrend : {'none', 'mean', 'linear'} or callable, default: 'none'
(4)                 The function applied to each segment before fft-ing, designed to remove
(4)                 the mean or linear trend.  Unlike in MATLAB, where the *detrend* parameter
(4)                 is a vector, in Matplotlib it is a function.  The :mod:`~matplotlib.mlab`
(4)                 module defines `.detrend_none`, `.detrend_mean`, and `.detrend_linear`,
(4)                 but you can use a custom function as well.  You can also use a string to
(4)                 choose one of the functions: 'none' calls `.detrend_none`. 'mean' calls
(4)                 `.detrend_mean`. 'linear' calls `.detrend_linear`.
(0)             scale_by_freq : bool, default: True
(4)                 Whether the resulting density values should be scaled by the scaling
(4)                 frequency, which gives density in units of 1/Hz.  This allows for
(4)                 integration over the returned frequency values.  The default is True for
(4)                 MATLAB compatibility.""")

(4)                 Compute a spectrogram.
(4)                 Compute and plot a spectrogram of data in *x*.  Data are split into
(4)                 *NFFT* length segments and the spectrum of each section is
(4)                 computed.  The windowing function *window* is applied to each
(4)                 segment, and the amount of overlap of each segment is
(4)                 specified with *noverlap*.
(4)                 Parameters
(4)                 ----------
(4)                 x : array-like
(8)                     1-D array or sequence.
(4)                 %(Spectral)s
(4)                 %(PSD)s
(4)                 noverlap : int, default: 128
(8)                     The number of points of overlap between blocks.
(4)                 mode : str, default: 'psd'
(8)                     What sort of spectrum to use:
(12)                        'psd'
(16)                            Returns the power spectral density.
(12)                        'complex'
(16)                            Returns the complex-valued frequency spectrum.
(12)                        'magnitude'
(16)                            Returns the magnitude spectrum.
(12)                        'angle'
(16)                            Returns the phase spectrum without unwrapping.
(12)                        'phase'
(16)                            Returns the phase spectrum with unwrapping.
(4)                 Returns
```

```
(4)                 -------
(4)                 spectrum : array-like
(8)                     2D array, columns are the periodograms of successive segments.
(4)                 freqs : array-like
(8)                     1-D array, frequencies corresponding to the rows in *spectrum*.
(4)                 t : array-like
(8)                     1-D array, the times corresponding to midpoints of segments
(8)                     (i.e the columns in *spectrum*).
(4)                 See Also
(4)                 --------
(4)                 psd : differs in the overlap and in the return values.
(4)                 complex_spectrum : similar, but with complex valued frequencies.
(4)                 magnitude_spectrum : similar single segment when *mode* is 'magnitude'.
(4)                 angle_spectrum : similar to single segment when *mode* is 'angle'.
(4)                 phase_spectrum : similar to single segment when *mode* is 'phase'.

(0)             def _get_packed_offsets(widths, total, sep, mode="fixed"):
(4)                 r"""
(4)                 Pack boxes specified by their *widths*.
(4)                 For simplicity of the description, the terminology used here assumes a
(4)                 horizontal layout, but the function works equally for a vertical layout.
(4)                 There are three packing *mode*\s:
(4)                 - 'fixed': The elements are packed tight to the left with a spacing of
(6)                   *sep* in between. If *total* is *None* the returned total will be the
(6)                   right edge of the last box. A non-*None* total will be passed unchecked
(6)                   to the output. In particular this means that right edge of the last
(6)                   box may be further to the right than the returned total.
(4)                 - 'expand': Distribute the boxes with equal spacing so that the left edge
(6)                   of the first box is at 0, and the right edge of the last box is at
(6)                   *total*. The parameter *sep* is ignored in this mode. A total of *None*
(6)                   is accepted and considered equal to 1. The total is returned unchanged
(6)                   (except for the conversion *None* to 1). If the total is smaller than
(6)                   the sum of the widths, the laid out boxes will overlap.
(4)                 - 'equal': If *total* is given, the total space is divided in N equal
(6)                   ranges and each box is left-aligned within its subspace.
(6)                   Otherwise (*total* is *None*), *sep* must be provided and each box is
(6)                   left-aligned in its subspace of width ``(max(widths) + sep)``. The
(6)                   total width is then calculated to be ``N * (max(widths) + sep)``.
(4)                 Parameters
(4)                 ----------
(4)                 widths : list of float
(8)                     Widths of boxes to be packed.
(4)                 total : float or None
(8)                     Intended total length. *None* if not used.
(4)                 sep : float or None
(8)                     Spacing between boxes.
```

```
(4)                 mode : {'fixed', 'expand', 'equal'}
(8)                     The packing mode.
(4)                 Returns
(4)                 -------
(4)                 total : float
(8)                     The total width needed to accommodate the laid out boxes.
(4)                 offsets : array of float
(8)                     The left offsets of the boxes.

(8)                     Parameters
(8)                     ----------
(8)                     loc : str
(12)                        The box location.  Valid locations are
(12)                        'upper left', 'upper center', 'upper right',
(12)                        'center left', 'center', 'center right',
(12)                        'lower left', 'lower center', 'lower right'.
(12)                        For backward compatibility, numeric values are accepted as well.
(12)                        See the parameter *loc* of `.Legend` for details.
(8)                     pad : float, default: 0.4
(12)                        Padding around the child as fraction of the fontsize.
(8)                     borderpad : float, default: 0.5
(12)                        Padding between the offsetbox frame and the *bbox_to_anchor*.
(8)                     child : `.OffsetBox`
(12)                        The box that will be anchored.
(8)                     prop : `.FontProperties`
(12)                        This is only used as a reference for paddings. If not given,
(12)                        :rc:`legend.fontsize` is used.
(8)                     frameon : bool
(12)                        Whether to draw a frame around the box.
(8)                     bbox_to_anchor : `.BboxBase`, 2-tuple, or 4-tuple of floats
(12)                        Box that is used to position the legend in conjunction with *loc*.
(8)                     bbox_transform : None or :class:`matplotlib.transforms.Transform`
(12)                        The transform for the bounding box (*bbox_to_anchor*).
(8)                     **kwargs
(12)                        All other parameters are passed on to `.OffsetBox`.
(8)                     Notes
(8)                     -----
(8)                     See `.Legend` for a detailed description of the anchoring mechanism.

(8)                     Parameters
(8)                     ----------
(8)                     offsetbox : `OffsetBox`
(8)                     xy : (float, float)
(12)                        The point *(x, y)* to annotate. The coordinate system is
determined
(12)                        by *xycoords*.
(8)                     xybox : (float, float), default: *xy*
(12)                        The position *(x, y)* to place the text at. The coordinate system
(12)                        is determined by *boxcoords*.
(8)                     xycoords : single or two-tuple of str or `.Artist` or `.Transform` or
\
(0)             callable, default: 'data'
```

```
(12)                        The coordinate system that *xy* is given in. See the parameter
(12)                        *xycoords* in `.Annotation` for a detailed description.
(8)                     boxcoords : single or two-tuple of str or `.Artist` or `.Transform` \
(0)             or callable, default: value of *xycoords*
(12)                        The coordinate system that *xybox* is given in. See the parameter
(12)                        *textcoords* in `.Annotation` for a detailed description.
(8)                     frameon : bool, default: True
(12)                        By default, the text is surrounded by a white `.FancyBboxPatch`
(12)                        (accessible as the ``patch`` attribute of the `.AnnotationBbox`).
(12)                        If *frameon* is set to False, this patch is made invisible.
(8)                     annotation_clip: bool or None, default: None
(12)                        Whether to clip (i.e. not draw) the annotation when the annotation
(12)                        point *xy* is outside the Axes area.
(12)                        - If *True*, the annotation will be clipped when *xy* is outside
(14)                          the Axes.
(12)                        - If *False*, the annotation will always be drawn.
(12)                        - If *None*, the annotation will be clipped when *xy* is outside
(14)                          the Axes and *xycoords* is 'data'.
(8)                     pad : float, default: 0.4
(12)                        Padding around the offsetbox.
(8)                     box_alignment : (float, float)
(12)                        A tuple of two floats for a vertical and horizontal alignment of
(12)                        the offset box w.r.t. the *boxcoords*.
(12)                        The lower-left corner is (0, 0) and upper-right corner is (1, 1).
(8)                     bboxprops : dict, optional
(12)                        A dictionary of properties to set for the annotation bounding box,
(12)                        for example *boxstyle* and *alpha*.  See `.FancyBboxPatch` for
(12)                        details.
(8)                     arrowprops: dict, optional
(12)                        Arrow properties, see `.Annotation` for description.
(8)                     fontsize: float or str, optional
(12)                        Translated to points and passed as *mutation_scale* into
(12)                        `.FancyBboxPatch` to scale attributes of the box style (e.g. pad
(12)                        or rounding_size).  The name is chosen in analogy to `.Text` where
(12)                        *fontsize* defines the mutation scale as well.  If not given,
(12)                        :rc:`legend.fontsize` is used.  See `.Text.set_fontsize` for valid
(12)                        values.
(8)                     **kwargs
(12)                        Other `AnnotationBbox` properties.  See `.AnnotationBbox.set` for
(12)                        a list.

(8)                 bool
(8)                 Notes
(8)                 -----
(8)                 The proper use of this method depends on the transform of the patch.
(8)                 Isolated patches do not have a transform. In this case, the patch
(8)                 creation coordinates and the point coordinates match. The following
(8)                 example checks that the center of a circle is within the circle
(8)                 >>> center = 0, 0
(8)                 >>> c = Circle(center, radius=1)
(8)                 >>> c.contains_point(center)
(8)                 True
(8)                 The convention of checking against the transformed patch stems from
(8)                 the fact that this method is predominantly used to check if display
(8)                 coordinates (e.g. from mouse events) are within the patch. If you want
(8)                 to do the above check with data coordinates, you have to properly
(8)                 transform them first:
(8)                 >>> center = 0, 0
(8)                 >>> c = Circle(center, radius=3)
(8)                 >>> plt.gca().add_patch(c)
(8)                 >>> transformed_interior_point = c.get_data_transform().transform((0,
2))
(8)                 >>> c.contains_point(transformed_interior_point)
(8)                 True
(8)                 """
(8)                 radius = self._process_radius(radius)
```

```
197: (8)                    return self.get_path().contains_point(point,
198: (46)                                                 self.get_transform(),
199: (46)                                                 radius)
200: (4)                def contains_points(self, points, radius=None):
201: (8)                    """
202: (8)                    Return whether the given points are inside the patch.
203: (8)                    Parameters
204: (8)                    ----------
205: (8)                    points : (N, 2) array
206: (12)                       The points to check, in target coordinates of
207: (12)                       ``self.get_transform()``. These are display coordinates for
patches
208: (12)                       that are added to a figure or Axes. Columns contain x and y
values.
209: (8)                    radius : float, optional
210: (12)                       Additional margin on the patch in target coordinates of
211: (12)                       `.Patch.get_transform`. See `.Path.contains_point` for further
212: (12)                       details.
213: (12)                       If `None`, the default value depends on the state of the object:
214: (12)                       - If `.Artist.get_picker` is a number, the default
215: (14)                         is that value.  This is so that picking works as expected.
216: (12)                       - Otherwise if the edge color has a non-zero alpha, the default
217: (14)                         is half of the linewidth.  This is so that all the colored
218: (14)                         pixels are "in" the patch.
219: (12)                       - Finally, if the edge has 0 alpha, the default is 0.  This is
220: (14)                         so that patches without a stroked edge do not have points
221: (14)                         outside of the filled region report as "in" due to an
222: (14)                         invisible edge.
223: (8)                    Returns
224: (8)                    -------
225: (8)                    length-N bool array

(8)                 Draw the arc to the given *renderer*.
(8)                 Notes
(8)                 -----
(8)                 Ellipses are normally drawn using an approximation that uses
(8)                 eight cubic Bezier splines.  The error of this approximation
(8)                 is 1.89818e-6, according to this unverified source:
(10)                  Lancaster, Don.  *Approximating a Circle or an Ellipse Using
(10)                  Four Bezier Cubic Splines.*
(10)                  https://www.tinaja.com/glib/ellipse4.pdf
(8)                 There is a use case where very large ellipses must be drawn
(8)                 with very high accuracy, and it is too expensive to render the
(8)                 entire ellipse with enough segments (either splines or line
(8)                 segments).  Therefore, in the case where either radius of the
(8)                 ellipse is large enough that the error of the spline
(8)                 approximation will be visible (greater than one pixel offset
(8)                 from the ideal), a different technique is used.
(8)                 In that case, only the visible parts of the ellipse are drawn,
(8)                 with each visible arc using a fixed number of spline segments
(8)                 (8).  The algorithm proceeds as follows:
(8)                 1. The points where the ellipse intersects the axes (or figure)
(11)                   bounding box are located.  (This is done by performing an inverse
(11)                   transformation on the bbox such that it is relative to the unit
(11)                   circle -- this makes the intersection calculation much easier than
(11)                   doing rotated ellipse intersection directly.)
(11)                   This uses the "line intersecting a circle" algorithm from:
(15)                       Vince, John.  *Geometry for Computer Graphics: Formulae,
(15)                       Examples & Proofs.*  London: Springer-Verlag, 2005.
(8)                 2. The angles of each of the intersection points are calculated.
(8)                 3. Proceeding counterclockwise starting in the positive
(11)                   x-direction, each of the visible arc-segments between the
(11)                   pairs of vertices are drawn using the Bezier arc
(11)                   approximation technique implemented in `.Path.arc`.
(8)                 """

(0)         class ArrowStyle(_Style):
(4)             """
(4)             `ArrowStyle` is a container class which defines several
(4)             arrowstyle classes, which is used to create an arrow path along a
(4)             given path.  These are mainly used with `FancyArrowPatch`.
(4)             An arrowstyle object can be either created as::
(11)                   ArrowStyle.Fancy(head_length=.4, head_width=.4, tail_width=.4)
(4)             or::
(11)                   ArrowStyle("Fancy", head_length=.4, head_width=.4, tail_width=.4)
(4)             or::
(11)                   ArrowStyle("Fancy, head_length=.4, head_width=.4, tail_width=.4")
(4)             The following classes are defined
(4)             %(ArrowStyle:table)s
(4)             For an overview of the visual appearance, see
(4)             :doc:`/gallery/text_labels_and_annotations/fancyarrow_demo`.
(4)             An instance of any arrow style class is a callable object,
(4)             whose call signature is::
(8)                 __call__(self, path, mutation_size, linewidth, aspect_ratio=1.)
(4)             and it returns a tuple of a `.Path` instance and a boolean
(4)             value. *path* is a `.Path` instance along which the arrow
(4)             will be drawn. *mutation_size* and *aspect_ratio* have the same
(4)             meaning as in `BoxStyle`. *linewidth* is a line width to be
(4)             stroked. This is meant to be used to correct the location of the
(4)             head so that it does not overshoot the destination point, but not all
(4)             classes support it.
(4)             Notes
(4)             -----
(4)             *angleA* and *angleB* specify the orientation of the bracket, as either a
(4)             clockwise or counterclockwise angle depending on the arrow type. 0 degrees
(4)             means perpendicular to the line connecting the arrow's head and tail.

3057: (8)                   xy : (float, float)
3058: (10)                    The lower left corner of the box.
3059: (8)                   width : float
3060: (12)                      The width of the box.
3061: (8)                   height : float
3062: (12)                      The height of the box.
```

```
(8)                 boxstyle : str or `~matplotlib.patches.BoxStyle`
(12)                    The style of the fancy box. This can either be a `.BoxStyle`
(12)                    instance or a string of the style name and optionally comma
(12)                    separated attributes (e.g. "Round, pad=0.2"). This string is
(12)                    passed to `.BoxStyle` to construct a `.BoxStyle` object. See
(12)                    there for a full documentation.
(12)                    The following box styles are available:
(12)                    %(BoxStyle:table)s
(8)                 mutation_scale : float, default: 1
(12)                    Scaling factor applied to the attributes of the box style
(12)                    (e.g. pad or rounding_size).
(8)                 mutation_aspect : float, default: 1
(12)                    The height of the rectangle will be squeezed by this value before
(12)                    the mutation and the mutated box will be stretched by the inverse
(12)                    of it. For example, this allows different horizontal and vertical
(12)                    padding.
(8)                 Other Parameters
(8)                 ----------------
(8)                 **kwargs : `~matplotlib.patches.Patch` properties
(8)                 %(Patch:kwdoc)s
(8)                 """
(8)                 super().__init__(**kwargs)
(8)                 self._x, self._y = xy
(8)                 self._width = width
(8)                 self._height = height

(8)                 self._mutation_scale = mutation_scale
(8)                 self._mutation_aspect = mutation_aspect
(8)                 self.stale = True
(4)             @_docstring.dedent_interpd
(4)             def set_boxstyle(self, boxstyle=None, **kwargs):
(8)                 """
(8)                 Set the box style, possibly with further attributes.
(8)                 Attributes from the previous box style are not reused.
(8)                 Without argument (or with ``boxstyle=None``), the available box styles
(8)                 are returned as a human-readable string.
(8)                 Parameters
(8)                 ----------
(8)                 boxstyle : str or `~matplotlib.patches.BoxStyle`
(12)                    The style of the box: either a `.BoxStyle` instance, or a string,
(12)                    which is the style name and optionally comma separated attributes
(12)                    (e.g. "Round,pad=0.2"). Such a string is used to construct a
(12)                    `.BoxStyle` object, as documented in that class.
(12)                    The following box styles are available:
(12)                    %(BoxStyle:table_and_accepts)s
(8)                 **kwargs
(12)                    Additional attributes for the box style. See the table above for
(12)                    supported parameters.
(8)                 Examples
(8)                 --------
(8)                 ::
(12)                    set_boxstyle("Round,pad=0.2")
(12)                    set_boxstyle("round", pad=0.2)
(8)                 """

(4)             A fancy arrow patch.
(4)             It draws an arrow using the `ArrowStyle`. It is primarily used by the
(4)             `~.axes.Axes.annotate` method.  For most purposes, use the annotate method
for
(4)             drawing arrows.
(4)             The head and tail positions are fixed at the specified start and end
points
(4)             of the arrow, but the size and shape (in display coordinates) of the arrow
(4)             does not change when the axis is moved or zoomed.
(4)             """
(4)             _edge_default = True

(8)                 """
(8)                 There are two ways for defining an arrow:
(8)                 - If *posA* and *posB* are given, a path connecting two points is
(10)                  created according to *connectionstyle*. The path will be
(10)                  clipped with *patchA* and *patchB* and further shrunken by
(10)                  *shrinkA* and *shrinkB*. An arrow is drawn along this
(10)                  resulting path using the *arrowstyle* parameter.
(8)                 - Alternatively if *path* is provided, an arrow is drawn along this
(10)                  path and *patchA*, *patchB*, *shrinkA*, and *shrinkB* are ignored.
(8)                 Parameters
(8)                 ----------
(8)                 posA, posB : (float, float), default: None
```

```
(12)                        (x, y) coordinates of arrow tail and arrow head respectively.
(8)                     path : `~matplotlib.path.Path`, default: None
(12)                        If provided, an arrow is drawn along this path and *patchA*,
(12)                        *patchB*, *shrinkA*, and *shrinkB* are ignored.
(8)                     arrowstyle : str or `.ArrowStyle`, default: 'simple'
(12)                        The `.ArrowStyle` with which the fancy arrow is drawn.  If a
(12)                        string, it should be one of the available arrowstyle names, with
(12)                        optional comma-separated attributes.  The optional attributes are
(12)                        meant to be scaled with the *mutation_scale*.  The following arrow
(12)                        styles are available:
(12)                        %(ArrowStyle:table)s
(8)                     connectionstyle : str or `.ConnectionStyle` or None, optional, \
(0)             default: 'arc3'
(12)                        The `.ConnectionStyle` with which *posA* and *posB* are connected.
(12)                        If a string, it should be one of the available connectionstyle
(12)                        names, with optional comma-separated attributes.  The following
(12)                        connection styles are available:
(12)                        %(ConnectionStyle:table)s
(8)                     patchA, patchB : `~matplotlib.patches.Patch`, default: None
(12)                        Head and tail patches, respectively.
(8)                     shrinkA, shrinkB : float, default: 2
(12)                        Shrink amount, in points, of the tail and head of the arrow
respectively.
(8)                     mutation_scale : float, default: 1
(12)                        Value with which attributes of *arrowstyle* (e.g., *head_length*)
(12)                        will be scaled.
(8)                     mutation_aspect : None or float, default: None
(12)                        The height of the rectangle will be squeezed by this value before
(12)                        the mutation and the mutated box will be stretched by the inverse
(12)                        of it.
(8)                     Other Parameters
(8)                     ----------------
(8)                     **kwargs : `~matplotlib.patches.Patch` properties, optional
(12)                        Here is a list of available `.Patch` properties:
(8)                     %(Patch:kwdoc)s
(12)                        In contrast to other patches, the default ``capstyle`` and
(12)                        ``joinstyle`` for `FancyArrowPatch` are set to ``"round"``.

```
(8)                     ====================
==================================================
(8)                     'figure points'      points from the lower left corner of the figure
(8)                     'figure pixels'      pixels from the lower left corner of the figure
(8)                     'figure fraction'    0, 0 is lower left of figure and 1, 1 is upper
(29)                                         right
(8)                     'subfigure points'   points from the lower left corner of the
subfigure
(8)                     'subfigure pixels'   pixels from the lower left corner of the
subfigure
(8)                     'subfigure fraction' fraction of the subfigure, 0, 0 is lower left.
(8)                     'axes points'        points from lower left corner of the Axes
(8)                     'axes pixels'        pixels from lower left corner of the Axes
(8)                     'axes fraction'      0, 0 is lower left of Axes and 1, 1 is upper
right
(8)                     'data'               use the coordinate system of the object being
(29)                                         annotated (default)
(8)                     'offset points'      offset (in points) from the *xy* value
(8)                     'polar'              you can specify *theta*, *r* for the annotation,
(29)                                         even in cartesian plots.  Note that if you are
(29)                                         using a polar Axes, you do not need to specify
(29)                                         polar for the coordinate system since that is the
(29)                                         native "data" coordinate system.
(8)                     ====================
==================================================
(8)                     Alternatively they can be set to any valid
(8)                     `~matplotlib.transforms.Transform`.
(8)                     Note that 'subfigure pixels' and 'figure pixels' are the same
(8)                     for the parent figure, so users who want code that is usable in
(8)                     a subfigure can use 'subfigure pixels'.

16: (0)             from .bezier import BezierSegment
17: (0)             class Path:
18: (4)                 """
19: (4)                 A series of possibly disconnected, possibly closed, line and curve
20: (4)                 segments.
21: (4)                 The underlying storage is made up of two parallel numpy arrays:
22: (4)                 - *vertices*: an (N, 2) float array of vertices
23: (4)                 - *codes*: an N-length `numpy.uint8` array of path codes, or None
24: (4)                 These two arrays always have the same length in the first
25: (4)                 dimension.  For example, to represent a cubic curve, you must
26: (4)                 provide three vertices and three `CURVE4` codes.
27: (4)                 The code types are:
28: (4)                 - `STOP`   :  1 vertex (ignored)
29: (8)                     A marker for the end of the entire path (currently not required and
30: (8)                     ignored)
31: (4)                 - `MOVETO` :  1 vertex
32: (8)                     Pick up the pen and move to the given vertex.
33: (4)                 - `LINETO` :  1 vertex
34: (8)                     Draw a line from the current position to the given vertex.
35: (4)                 - `CURVE3` :  1 control point, 1 endpoint
36: (8)                     Draw a quadratic Bézier curve from the current position, with the
given
37: (8)                     control point, to the given end point.
38: (4)                 - `CURVE4` :  2 control points, 1 endpoint
39: (8)                     Draw a cubic Bézier curve from the current position, with the given
40: (8)                     control points, to the given end point.
41: (4)                 - `CLOSEPOLY` : 1 vertex (ignored)
42: (8)                     Draw a line segment to the start point of the current polyline.
43: (4)                 If *codes* is None, it is interpreted as a `MOVETO` followed by a series
44: (4)                 of `LINETO`.
45: (4)                 Users of Path objects should not access the vertices and codes arrays
46: (4)                 directly.  Instead, they should use `iter_segments` or `cleaned` to get
the
47: (4)                 vertex/code pairs.  This helps, in particular, to consistently handle the
48: (4)                 case of *codes* being None.
49: (4)                 Some behavior of Path objects can be controlled by rcParams. See the
50: (4)                 rcParams whose keys start with 'path.'.
51: (4)                 .. note::
52: (8)                     The vertices and codes arrays should be treated as

File 54 - pylab.py:

```
1: (0)              """
2: (0)              `pylab` is a historic interface and its use is strongly discouraged. The
equivalent
3: (0)              replacement is `matplotlib.pyplot`.  See :ref:`api_interfaces` for a full
overview
4: (0)              of Matplotlib interfaces.
5: (0)              `pylab` was designed to support a MATLAB-like way of working with all plotting
related
6: (0)              functions directly available in the global namespace. This was achieved
through a
7: (0)              wildcard import (``from pylab import *``).
8: (0)              .. warning::
9: (3)                 The use of `pylab` is discouraged for the following reasons:
10: (3)                ``from pylab import *`` imports all the functions from `matplotlib.pyplot`,
`numpy`,
11: (3)                `numpy.fft`, `numpy.linalg`, and `numpy.random`, and some additional
functions into
12: (3)                the global namespace.
13: (3)                Such a pattern is considered bad practice in modern python, as it clutters
the global
14: (3)                namespace. Even more severely, in the case of `pylab`, this will overwrite
some
```

```
15: (3)                 builtin functions (e.g. the builtin `sum` will be replaced by `numpy.sum`),
which
16: (3)                 can lead to unexpected behavior.

(4)                 Display all open figures.
(4)                 Parameters
(4)                 ----------
(4)                 block : bool, optional
(8)                     Whether to wait for all figures to be closed before returning.
(8)                     If `True` block and run the GUI main loop until all figure windows
(8)                     are closed.
(8)                     If `False` ensure that all figure windows are displayed and return
(8)                     immediately.  In this case, you are responsible for ensuring
(8)                     that the event loop is running to have responsive figures.
(8)                     Defaults to True in non-interactive mode and to False in interactive
(8)                     mode (see `.pyplot.isinteractive`).
(4)                 See Also
(4)                 --------
(4)                 ion : Enable interactive mode, which shows / updates the figure after
(10)                      every plotting command, so that calling ``show()`` is not necessary.
(4)                 ioff : Disable interactive mode.
(4)                 savefig : Save the figure to an image file instead of showing it on
screen.
(4)                 Notes
(4)                 -----
(4)                 **Saving figures to file and showing a window at the same time**
(4)                 If you want an image file as well as a user interface window, use
(4)                 `.pyplot.savefig` before `.pyplot.show`. At the end of (a blocking)
(4)                 ``show()`` the figure is closed and thus unregistered from pyplot. Calling
(4)                 `.pyplot.savefig` afterwards would save a new and thus empty figure. This
(4)                 limitation of command order does not apply if the show is non-blocking or
(4)                 if you keep a reference to the figure and use `.Figure.savefig`.
(4)                 **Auto-show in jupyter notebooks**
(4)                 The jupyter backends (activated via ``%matplotlib inline``,
(4)                 ``%matplotlib notebook``, or ``%matplotlib widget``), call ``show()`` at
(4)                 the end of every cell by default. Thus, you usually don't have to call it
(4)                 explicitly there.
(4)                 """

611: (0)            ) -> Figure:
612: (4)                """
613: (4)                Create a new figure, or activate an existing figure.
614: (4)                Parameters
615: (4)                ----------
616: (4)                num : int or str or `.Figure` or `.SubFigure`, optional
617: (8)                    A unique identifier for the figure.
618: (8)                    If a figure with that identifier already exists, this figure is made
619: (8)                    active and returned. An integer refers to the ``Figure.number``
620: (8)                    attribute, a string refers to the figure label.
621: (8)                    If there is no figure with the identifier or *num* is not given, a new
622: (8)                    figure is created, made active and returned.  If *num* is an int, it
623: (8)                    will be used for the ``Figure.number`` attribute, otherwise, an
624: (8)                    auto-generated integer value is used (starting at 1 and incremented
625: (8)                    for each new figure). If *num* is a string, the figure label and the
626: (8)                    window title is set to this value.  If num is a ``SubFigure``, its
627: (8)                    parent ``Figure`` is activated.
628: (4)                figsize : (float, float), default: :rc:`figure.figsize`
629: (8)                    Width, height in inches.
630: (4)                dpi : float, default: :rc:`figure.dpi`
631: (8)                    The resolution of the figure in dots-per-inch.
632: (4)                facecolor : :mpltype:`color`, default: :rc:`figure.facecolor`
```

```
(8)                 The background color.
(4)             edgecolor : :mpltype:`color`, default: :rc:`figure.edgecolor`
(8)                 The border color.
(4)             frameon : bool, default: True
(8)                 If False, suppress drawing the figure frame.
(4)             FigureClass : subclass of `~matplotlib.figure.Figure`
(8)                 If set, an instance of this subclass will be created, rather than a
(8)                 plain `.Figure`.
(4)             clear : bool, default: False
(8)                 If True and the figure already exists, then it is cleared.
(4)             layout : {'constrained', 'compressed', 'tight', 'none', `.LayoutEngine`,
None}, \
(0)         default: None
(8)                 The layout mechanism for positioning of plot elements to avoid
(8)                 overlapping Axes decorations (labels, ticks, etc). Note that layout
(8)                 managers can measurably slow down figure display.
(8)                 - 'constrained': The constrained layout solver adjusts Axes sizes
(10)                  to avoid overlapping Axes decorations.  Can handle complex plot
(10)                  layouts and colorbars, and is thus recommended.
(10)                  See :ref:`constrainedlayout_guide`
(10)                  for examples.
(8)                 - 'compressed': uses the same algorithm as 'constrained', but
(10)                  removes extra space between fixed-aspect-ratio Axes.  Best for
(10)                  simple grids of Axes.
(8)                 - 'tight': Use the tight layout mechanism. This is a relatively
(10)                  simple algorithm that adjusts the subplot parameters so that
(10)                  decorations do not overlap. See `.Figure.set_tight_layout` for
(10)                  further details.
(8)                 - 'none': Do not use a layout engine.
(8)                 - A `.LayoutEngine` instance. Builtin layout classes are
(10)                  `.ConstrainedLayoutEngine` and `.TightLayoutEngine`, more easily
(10)                  accessible by 'constrained' and 'tight'.  Passing an instance
(10)                  allows third parties to provide their own layout engine.
(8)                 If not given, fall back to using the parameters *tight_layout* and
(8)                 *constrained_layout*, including their config defaults
(8)                 :rc:`figure.autolayout` and :rc:`figure.constrained_layout.use`.
(4)             **kwargs
(8)                 Additional keyword arguments are passed to the `.Figure` constructor.
(4)             Returns
(4)             -------
(4)             `~matplotlib.figure.Figure`
(4)             Notes
(4)             -----
(4)             A newly created figure is passed to the `~.FigureCanvasBase.new_manager`
(4)             method or the `new_figure_manager` function provided by the current
(4)             backend, which install a canvas and a manager on the figure.
(4)             Once this is done, :rc:`figure.hooks` are called, one at a time, on the
(4)             figure; these hooks allow arbitrary customization of the figure (e.g.,
(4)             attaching callbacks) or of associated elements (e.g., modifying the
(4)             toolbar).  See :doc:`/gallery/user_interfaces/mplcvd` for an example of
(4)             toolbar customization.
(4)             If you are creating many figures, make sure you explicitly call
(4)             `.pyplot.close` on the figures you are not using, because this will
(4)             enable pyplot to properly clean up the memory.
(4)             `~matplotlib.rcParams` defines the default values, which can be modified
(4)             in the matplotlibrc file.

(8)                     plt.axes()
(8)                     plt.axes(rect, projection=None, polar=False, **kwargs)
(8)                     plt.axes(ax)
(4)                 Parameters
(4)                 ----------
(4)                 arg : None or 4-tuple
(8)                     The exact behavior of this function depends on the type:
(8)                     - *None*: A new full window Axes is added using
(10)                      ``subplot(**kwargs)``.
(8)                     - 4-tuple of floats *rect* = ``(left, bottom, width, height)``.
(10)                      A new Axes is added with dimensions *rect* in normalized
(10)                      (0, 1) units using `~.Figure.add_axes` on the current figure.
(4)                 projection : {None, 'aitoff', 'hammer', 'lambert', 'mollweide', \
(0)             'polar', 'rectilinear', str}, optional
(8)                     The projection type of the `~.axes.Axes`. *str* is the name of
(8)                     a custom projection, see `~matplotlib.projections`. The default
```

```
(8)                 None results in a 'rectilinear' projection.
(4)             polar : bool, default: False
(8)                 If True, equivalent to projection='polar'.
(4)             sharex, sharey : `~matplotlib.axes.Axes`, optional
(8)                 Share the x or y `~matplotlib.axis` with sharex and/or sharey.
(8)                 The axis will have the same limits, ticks, and scale as the axis
(8)                 of the shared Axes.
(4)             label : str
(8)                 A label for the returned Axes.
(4)             Returns
(4)             -------
(4)             `~.axes.Axes`, or a subclass of `~.axes.Axes`
(8)                 The returned Axes class depends on the projection used. It is
(8)                 `~.axes.Axes` if rectilinear projection is used and
(8)                 `.projections.polar.PolarAxes` if polar projection is used.
(4)             Other Parameters
(4)             ----------------
(4)             **kwargs
(8)                 This method also takes the keyword arguments for
(8)                 the returned Axes class. The keyword arguments for the
(8)                 rectilinear Axes class `~.axes.Axes` can be found in
(8)                 the following table but there might also be other keyword
(8)                 arguments if another projection is used, see the actual Axes
(8)                 class.

(4)             Add an Axes to the current figure or retrieve an existing Axes.
(4)             This is a wrapper of `.Figure.add_subplot` which provides additional
(4)             behavior when working with the implicit API (see the notes section).
```

```
(4)                 Call signatures::
(7)                    subplot(nrows, ncols, index, **kwargs)
(7)                    subplot(pos, **kwargs)
(7)                    subplot(**kwargs)
(7)                    subplot(ax)
(4)                 Parameters
(4)                 ----------
(4)                 *args : int, (int, int, *index*), or `.SubplotSpec`, default: (1, 1, 1)
(8)                     The position of the subplot described by one of
(8)                     - Three integers (*nrows*, *ncols*, *index*). The subplot will take
the
(10)                      *index* position on a grid with *nrows* rows and *ncols* columns.
(10)                      *index* starts at 1 in the upper left corner and increases to the
(10)                      right. *index* can also be a two-tuple specifying the (*first*,
(10)                      *last*) indices (1-based, and including *last*) of the subplot,
e.g.,
(10)                      ``fig.add_subplot(3, 1, (1, 2))`` makes a subplot that spans the
(10)                      upper 2/3 of the figure.
(8)                     - A 3-digit integer. The digits are interpreted as if given separately
(10)                      as three single-digit integers, i.e. ``fig.add_subplot(235)`` is the
(10)                      same as ``fig.add_subplot(2, 3, 5)``. Note that this can only be
used
(10)                      if there are no more than 9 subplots.
(8)                     - A `.SubplotSpec`.
(4)                 projection : {None, 'aitoff', 'hammer', 'lambert', 'mollweide', \
(0)             'polar', 'rectilinear', str}, optional
(8)                     The projection type of the subplot (`~.axes.Axes`). *str* is the name
(8)                     of a custom projection, see `~matplotlib.projections`. The default
(8)                     None results in a 'rectilinear' projection.
(4)                 polar : bool, default: False
(8)                     If True, equivalent to projection='polar'.
(4)                 sharex, sharey : `~matplotlib.axes.Axes`, optional
(8)                     Share the x or y `~matplotlib.axis` with sharex and/or sharey. The
(8)                     axis will have the same limits, ticks, and scale as the axis of the
(8)                     shared Axes.
(4)                 label : str
(8)                     A label for the returned Axes.
(4)                 Returns
(4)                 -------
(4)                 `~.axes.Axes`
(8)                     The Axes of the subplot. The returned Axes can actually be an instance
(8)                     of a subclass, such as `.projections.polar.PolarAxes` for polar
(8)                     projections.
(4)                 Other Parameters
(4)                 ----------------
(4)                 **kwargs
(8)                     This method also takes the keyword arguments for the returned Axes
(8)                     base class; except for the *figure* argument. The keyword arguments
(8)                     for the rectilinear base class `~.axes.Axes` can be found in
(8)                     the following table but there might also be other keyword
(8)                     arguments if another projection is used.
(8)                     %(Axes:kwdoc)s
(4)                 Notes
(4)                 -----
(4)                 Creating a new Axes will delete any preexisting Axes that
(4)                 overlaps with it beyond sharing a boundary::
(8)                     import matplotlib.pyplot as plt
(8)                     plt.plot([1, 2, 3])
(8)                     plt.subplot(211)
(4)                 If you do not want this behavior, use the `.Figure.add_subplot` method
(4)                 or the `.pyplot.axes` function instead.
(4)                 If no *kwargs* are passed and there exists an Axes in the location
(4)                 specified by *args* then that Axes will be returned rather than a new
(4)                 Axes being created.
(4)                 If *kwargs* are passed and there exists an Axes in the location
(4)                 specified by *args*, the projection type is the same, and the
(4)                 *kwargs* match with the existing Axes, then the existing Axes is
(4)                 returned.  Otherwise a new Axes is created with the specified
(4)                 parameters.  We save a reference to the *kwargs* which we use
```

```
(4)                 for this comparison.  If any of the values in *kwargs* are
(4)                 mutable we will not detect the case where they are mutated.
(4)                 In these cases we suggest using `.Figure.add_subplot` and the
(4)                 explicit Axes API rather than the implicit pyplot API.

(0)         ) -> tuple[Figure, Any]:
(4)             """
(4)             Create a figure and a set of subplots.
(4)             This utility wrapper makes it convenient to create common layouts of
(4)             subplots, including the enclosing figure object, in a single call.
(4)             Parameters
(4)             ----------
(4)             nrows, ncols : int, default: 1
(8)                 Number of rows/columns of the subplot grid.
(4)             sharex, sharey : bool or {'none', 'all', 'row', 'col'}, default: False
(8)                 Controls sharing of properties among x (*sharex*) or y (*sharey*)
(8)                 axes:
(8)                 - True or 'all': x- or y-axis will be shared among all subplots.
(8)                 - False or 'none': each subplot x- or y-axis will be independent.
(8)                 - 'row': each subplot row will share an x- or y-axis.
(8)                 - 'col': each subplot column will share an x- or y-axis.
(8)                 When subplots have a shared x-axis along a column, only the x tick
(8)                 labels of the bottom subplot are created. Similarly, when subplots
(8)                 have a shared y-axis along a row, only the y tick labels of the first
(8)                 column subplot are created. To later turn other subplots' ticklabels
(8)                 on, use `~matplotlib.axes.Axes.tick_params`.
(8)                 When subplots have a shared axis that has units, calling
(8)                 `.Axis.set_units` will update each axis with the new units.
(8)                 Note that it is not possible to unshare axes.
(4)             squeeze : bool, default: True
(8)                 - If True, extra dimensions are squeezed out from the returned
(10)                  array of `~matplotlib.axes.Axes`:
(10)                  - if only one subplot is constructed (nrows=ncols=1), the
(12)                    resulting single Axes object is returned as a scalar.
```

```
(10)                    - for Nx1 or 1xM subplots, the returned object is a 1D numpy
(12)                      object array of Axes objects.
(10)                    - for NxM, subplots with N>1 and M>1 are returned as a 2D array.
(8)                   - If False, no squeezing at all is done: the returned Axes object is
(10)                    always a 2D array containing Axes instances, even if it ends up
(10)                    being 1x1.
(4)               width_ratios : array-like of length *ncols*, optional
(8)                   Defines the relative widths of the columns. Each column gets a
(8)                   relative width of ``width_ratios[i] / sum(width_ratios)``.
(8)                   If not given, all columns will have the same width.  Equivalent
(8)                   to ``gridspec_kw={'width_ratios': [...]}``.
(4)               height_ratios : array-like of length *nrows*, optional
(8)                   Defines the relative heights of the rows. Each row gets a
(8)                   relative height of ``height_ratios[i] / sum(height_ratios)``.
(8)                   If not given, all rows will have the same height. Convenience
(8)                   for ``gridspec_kw={'height_ratios': [...]}``.
(4)               subplot_kw : dict, optional
(8)                   Dict with keywords passed to the
(8)                   `~matplotlib.figure.Figure.add_subplot` call used to create each
(8)                   subplot.
(4)               gridspec_kw : dict, optional
(8)                   Dict with keywords passed to the `~matplotlib.gridspec.GridSpec`
(8)                   constructor used to create the grid the subplots are placed on.
(4)               **fig_kw
(8)                   All additional keyword arguments are passed to the
(8)                   `.pyplot.figure` call.
(4)               Returns
(4)               -------
(4)               fig : `.Figure`
(4)               ax : `~matplotlib.axes.Axes` or array of Axes
(8)                   *ax* can be either a single `~.axes.Axes` object, or an array of Axes
(8)                   objects if more than one subplot was created.  The dimensions of the
(8)                   resulting array can be controlled with the squeeze keyword, see above.
(8)                   Typical idioms for handling the return value are::
(12)                      fig, ax = plt.subplots()
(12)                      fig, axs = plt.subplots(2, 2)
(12)                      fig, (ax1, ax2) = plt.subplots(1, 2)
(12)                      fig, ((ax1, ax2), (ax3, ax4)) = plt.subplots(2, 2)
(8)                   The names ``ax`` and pluralized ``axs`` are preferred over ``axes``
(8)                   because for the latter it's not clear if it refers to a single
(8)                   `~.axes.Axes` instance or a collection of these.

1309: (4)               """
1310: (4)               Build a layout of Axes based on ASCII art or nested lists.
```

```
(4)                 This is a helper function to build complex GridSpec layouts visually.
(4)                 See :ref:`mosaic`
(4)                 for an example and full API documentation
(4)                 Parameters
(4)                 ----------
(4)                 mosaic : list of list of {hashable or nested} or str
(8)                     A visual layout of how you want your Axes to be arranged
(8)                     labeled as strings.  For example ::
(11)                       x = [['A panel', 'A panel', 'edge'],
(16)                            ['C panel', '.',       'edge']]
(8)                     produces 4 Axes:
(8)                     - 'A panel' which is 1 row high and spans the first two columns
(8)                     - 'edge' which is 2 rows high and is on the right edge
(8)                     - 'C panel' which in 1 row and 1 column wide in the bottom left
(8)                     - a blank space 1 row and 1 column wide in the bottom center
(8)                     Any of the entries in the layout can be a list of lists
(8)                     of the same form to create nested layouts.
(8)                     If input is a str, then it must be of the form ::
(10)                      '''
(10)                      AAE
(10)                      C.E
(10)                      '''
(8)                     where each character is a column and each line is a row.
(8)                     This only allows only single character Axes labels and does
(8)                     not allow nesting but is very terse.
(4)                 sharex, sharey : bool, default: False
(8)                     If True, the x-axis (*sharex*) or y-axis (*sharey*) will be shared
(8)                     among all subplots.  In that case, tick label visibility and axis
units
(8)                     behave as for `subplots`.  If False, each subplot's x- or y-axis will
(8)                     be independent.
(4)                 width_ratios : array-like of length *ncols*, optional
(8)                     Defines the relative widths of the columns. Each column gets a
(8)                     relative width of ``width_ratios[i] / sum(width_ratios)``.
(8)                     If not given, all columns will have the same width.  Convenience
(8)                     for ``gridspec_kw={'width_ratios': [...]}``.
(4)                 height_ratios : array-like of length *nrows*, optional
(8)                     Defines the relative heights of the rows. Each row gets a
(8)                     relative height of ``height_ratios[i] / sum(height_ratios)``.
(8)                     If not given, all rows will have the same height. Convenience
(8)                     for ``gridspec_kw={'height_ratios': [...]}``.
(4)                 empty_sentinel : object, optional
(8)                     Entry in the layout to mean "leave this space empty".  Defaults
(8)                     to ``'.'``. Note, if *layout* is a string, it is processed via
(8)                     `inspect.cleandoc` to remove leading white space, which may
(8)                     interfere with using white-space as the empty sentinel.
(4)                 subplot_kw : dict, optional
(8)                     Dictionary with keywords passed to the `.Figure.add_subplot` call
(8)                     used to create each subplot.  These values may be overridden by
(8)                     values in *per_subplot_kw*.
(4)                 per_subplot_kw : dict, optional
(8)                     A dictionary mapping the Axes identifiers or tuples of identifiers
(8)                     to a dictionary of keyword arguments to be passed to the
(8)                     `.Figure.add_subplot` call used to create each subplot.  The values
(8)                     in these dictionaries have precedence over the values in
(8)                     *subplot_kw*.
(8)                     If *mosaic* is a string, and thus all keys are single characters,
(8)                     it is possible to use a single string instead of a tuple as keys;
(8)                     i.e. ``"AB"`` is equivalent to ``("A", "B")``.
(8)                     .. versionadded:: 3.7
(4)                 gridspec_kw : dict, optional
(8)                     Dictionary with keywords passed to the `.GridSpec` constructor used
(8)                     to create the grid the subplots are placed on.
(4)                 **fig_kw
(8)                     All additional keyword arguments are passed to the
(8)                     `.pyplot.figure` call.
(4)                 Returns
(4)                 -------
(4)                 fig : `.Figure`
```

```
(7)                 The new figure
(4)             dict[label, Axes]
(7)                 A dictionary mapping the labels to the Axes objects.  The order of
(7)                 the Axes is left-to-right and top-to-bottom of their position in the
(7)                 total layout.

(4)             """
(4)             Create a subplot at a specific location inside a regular grid.
(4)             Parameters
(4)             ----------
(4)             shape : (int, int)
(8)                 Number of rows and of columns of the grid in which to place axis.
(4)             loc : (int, int)
(8)                 Row number and column number of the axis location within the grid.
(4)             rowspan : int, default: 1
(8)                 Number of rows for the axis to span downwards.
(4)             colspan : int, default: 1
(8)                 Number of columns for the axis to span to the right.
(4)             fig : `.Figure`, optional
(8)                 Figure to place the subplot in. Defaults to the current figure.
(4)             **kwargs
(8)                 Additional keyword arguments are handed to `~.Figure.add_subplot`.
(4)             Returns
(4)             -------
(4)             `~.axes.Axes`
(8)                 The Axes of the subplot. The returned Axes can actually be an instance
(8)                 of a subclass, such as `.projections.polar.PolarAxes` for polar
(8)                 projections.
(4)             Notes
(4)             -----

 1767: (4)              Get or set the theta gridlines on the current polar plot.
 1768: (4)              Call signatures::
 1769: (5)               lines, labels = thetagrids()
 1770: (5)               lines, labels = thetagrids(angles, labels=None, fmt=None, **kwargs)
 1771: (4)              When called with no arguments, `.thetagrids` simply returns the tuple
 1772: (4)              (*lines*, *labels*). When called with arguments, the labels will
 1773: (4)              appear at the specified angles.
 1774: (4)              Parameters
 1775: (4)              ----------
 1776: (4)              angles : tuple with floats, degrees
 1777: (8)                  The angles of the theta gridlines.
 1778: (4)              labels : tuple with strings or None
 1779: (8)                  The labels to use at each radial gridline. The
 1780: (8)                  `.projections.polar.ThetaFormatter` will be used if None.
 1781: (4)              fmt : str or None
 1782: (8)                  Format string used in `matplotlib.ticker.FormatStrFormatter`.
 1783: (8)                  For example '%f'. Note that the angle in radians will be used.
 1784: (4)              Returns
```

```
(4)             -------
(4)             lines : list of `.lines.Line2D`
(8)                 The theta gridlines.
(4)             labels : list of `.text.Text`
(8)                 The tick labels.
(4)             Other Parameters
(4)             ----------------
(4)             **kwargs
(8)                 *kwargs* are optional `.Text` properties for the labels.

----------------------------------------

File 56 - quiver.py:

1: (0)             """
2: (0)             Support for plotting vector fields.
3: (0)             Presently this contains Quiver and Barb. Quiver plots an arrow in the
4: (0)             direction of the vector, with the size of the arrow related to the
```

```
 5: (0)             magnitude of the vector.
 6: (0)             Barbs are like quiver in that they point along a vector, but
 7: (0)             the magnitude of the vector is given schematically by the presence of barbs
 8: (0)             or flags on the barb.
 9: (0)             This will also become a home for things such as standard
10: (0)             deviation ellipses, which can and will be derived very easily from
11: (0)             the Quiver code.
12: (0)             """
13: (0)             import math
14: (0)             import numpy as np
15: (0)             from numpy import ma
16: (0)             from matplotlib import _api, cbook, _docstring
17: (0)             import matplotlib.artist as martist
18: (0)             import matplotlib.collections as mcollections
19: (0)             from matplotlib.patches import CirclePolygon
20: (0)             import matplotlib.text as mtext
21: (0)             import matplotlib.transforms as transforms
22: (0)             _quiver_doc = """
23: (0)             Plot a 2D field of arrows.
24: (0)             Call signature::
25: (2)               quiver([X, Y], U, V, [C], **kwargs)
26: (0)             *X*, *Y* define the arrow locations, *U*, *V* define the arrow directions, and
27: (0)             *C* optionally sets the color.
28: (0)             **Arrow length**
29: (0)             The default settings auto-scales the length of the arrows to a reasonable
size.
30: (0)             To change this behavior see the *scale* and *scale_units* parameters.
31: (0)             **Arrow shape**
32: (0)             The arrow shape is determined by *width*, *headwidth*, *headlength* and
33: (0)             *headaxislength*. See the notes below.
34: (0)             **Arrow styling**
35: (0)             Each arrow is internally represented by a filled polygon with a default edge
36: (0)             linewidth of 0. As a result, an arrow is rather a filled area, not a line with
37: (0)             a head, and `.PolyCollection` properties like *linewidth*, *edgecolor*,
38: (0)             *facecolor*, etc. act accordingly.
39: (0)             Parameters
40: (0)             ----------
41: (0)             X, Y : 1D or 2D array-like, optional
42: (4)                 The x and y coordinates of the arrow locations.
43: (4)                 If not given, they will be generated as a uniform integer meshgrid based
44: (4)                 on the dimensions of *U* and *V*.
45: (4)                 If *X* and *Y* are 1D but *U*, *V* are 2D, *X*, *Y* are expanded to 2D
46: (4)                 using ``X, Y = np.meshgrid(X, Y)``. In this case ``len(X)`` and ``len(Y)``
47: (4)                 must match the column and row dimensions of *U* and *V*.
48: (0)             U, V : 1D or 2D array-like
49: (4)                 The x and y direction components of the arrow vectors. The interpretation
50: (4)                 of these components (in data or in screen space) depends on *angles*.
51: (4)                 *U* and *V* must have the same number of elements, matching the number of
52: (4)                 arrow locations in *X*, *Y*. *U* and *V* may be masked. Locations masked
53: (4)                 in any of *U*, *V*, and *C* will not be drawn.
54: (0)             C : 1D or 2D array-like, optional
55: (4)                 Numeric data that defines the arrow colors by colormapping via *norm* and
56: (4)                 *cmap*.
57: (4)                 This does not support explicit colors. If you want to set colors directly,
58: (4)                 use *color* instead.  The size of *C* must match the number of arrow
59: (4)                 locations.
60: (0)             angles : {'uv', 'xy'} or array-like, default: 'uv'
61: (4)                 Method for determining the angle of the arrows.
62: (4)                 - 'uv': Arrow direction in screen coordinates. Use this if the arrows
63: (6)                   symbolize a quantity that is not based on *X*, *Y* data coordinates.
64: (6)                   If *U* == *V* the orientation of the arrow on the plot is 45 degrees
65: (6)                   counter-clockwise from the horizontal axis (positive to the right).
66: (4)                 - 'xy': Arrow direction in data coordinates, i.e. the arrows point from
67: (6)                   (x, y) to (x+u, y+v). Use this e.g. for plotting a gradient field.
68: (4)                 - Arbitrary angles may be specified explicitly as an array of values
69: (6)                   in degrees, counter-clockwise from the horizontal axis.
70: (6)                   In this case *U*, *V* is only used to determine the length of the
71: (6)                   arrows.
72: (4)                 Note: inverting a data axis will correspondingly invert the
```

```
 73: (4)                arrows only with ``angles='xy'``.
 74: (0)            pivot : {'tail', 'mid', 'middle', 'tip'}, default: 'tail'
 75: (4)                The part of the arrow that is anchored to the *X*, *Y* grid. The arrow
 76: (4)                rotates about this point.
 77: (4)                'mid' is a synonym for 'middle'.
 78: (0)            scale : float, optional
 79: (4)                Scales the length of the arrow inversely.
 80: (4)                Number of data units per arrow length unit, e.g., m/s per plot width; a
 81: (4)                smaller scale parameter makes the arrow longer. Default is *None*.
 82: (4)                If *None*, a simple autoscaling algorithm is used, based on the average
 83: (4)                vector length and the number of vectors. The arrow length unit is given by
 84: (4)                the *scale_units* parameter.
 85: (0)            scale_units : {'width', 'height', 'dots', 'inches', 'x', 'y', 'xy'}, optional
 86: (4)                If the *scale* kwarg is *None*, the arrow length unit. Default is *None*.
 87: (4)                e.g. *scale_units* is 'inches', *scale* is 2.0, and ``(u, v) = (1, 0)``,
 88: (4)                then the vector will be 0.5 inches long.
 89: (4)                If *scale_units* is 'width' or 'height', then the vector will be half the
 90: (4)                width/height of the axes.
 91: (4)                If *scale_units* is 'x' then the vector will be 0.5 x-axis
 92: (4)                units. To plot vectors in the x-y plane, with u and v having
 93: (4)                the same units as x and y, use
 94: (4)                ``angles='xy', scale_units='xy', scale=1``.
 95: (0)            units : {'width', 'height', 'dots', 'inches', 'x', 'y', 'xy'}, default:
'width'
 96: (4)
 97: (4)                Affects the arrow size (except for the length). In particular, the shaft
 98: (4)                *width* is measured in multiples of this unit.
 99: (4)                Supported values are:
100: (4)                - 'width', 'height': The width or height of the Axes.
101: (4)                - 'dots', 'inches': Pixels or inches based on the figure dpi.
102: (4)                - 'x', 'y', 'xy': *X*, *Y* or :math:`\\sqrt{X^2 + Y^2}` in data units.
103: (4)                The following table summarizes how these values affect the visible arrow
104: (4)                size under zooming and figure size changes:
105: (4)                =================  =================   ==================
106: (4)                units              zoom                figure size change
107: (4)                =================  =================   ==================
108: (4)                'x', 'y', 'xy'     arrow size scales   —
109: (4)                'width', 'height'  —                   arrow size scales
110: (4)                'dots', 'inches'   —                   —
111: (4)                =================  =================   ==================
112: (0)            width : float, optional
113: (4)                Shaft width in arrow units. All head parameters are relative to *width*.
114: (4)                The default depends on choice of *units* above, and number of vectors;
115: (4)                a typical starting value is about 0.005 times the width of the plot.
116: (0)            headwidth : float, default: 3
117: (4)                Head width as multiple of shaft *width*. See the notes below.
118: (0)            headlength : float, default: 5
119: (4)                Head length as multiple of shaft *width*. See the notes below.
120: (0)            headaxislength : float, default: 4.5
121: (4)                Head length at shaft intersection as multiple of shaft *width*.
122: (4)                See the notes below.
123: (0)            minshaft : float, default: 1
124: (4)                Length below which arrow scales, in units of head length. Do not
125: (4)                set this to less than 1, or small arrows will look terrible!
126: (0)            minlength : float, default: 1
127: (4)                Minimum length as a multiple of shaft width; if an arrow length
128: (4)                is less than this, plot a dot (hexagon) of this diameter instead.
129: (0)            color : :mpltype:`color` or list :mpltype:`color`, optional
130: (4)                Explicit color(s) for the arrows. If *C* has been set, *color* has no
131: (4)                effect.
132: (4)                This is a synonym for the `.PolyCollection` *facecolor* parameter.
133: (0)            Other Parameters
134: (0)            ----------------
135: (0)            data : indexable object, optional
136: (4)                DATA_PARAMETER_PLACEHOLDER
137: (0)            **kwargs : `~matplotlib.collections.PolyCollection` properties, optional
138: (4)                All other keyword arguments are passed on to `.PolyCollection`:
139: (4)                %(PolyCollection:kwdoc)s
140: (0)            Returns
141: (0)            -------

(0)            --------
(0)            .Axes.quiverkey : Add a key to a quiver plot.
(0)            Notes
(0)            -----
(0)            **Arrow shape**
(0)            The arrow is drawn as a polygon using the nodes as shown below. The values
(0)            *headwidth*, *headlength*, and *headaxislength* are in units of *width*.
(0)            .. image:: /_static/quiver_sizes.svg
(3)               :width: 500px
(0)            The defaults give a slightly swept-back arrow. Here are some guidelines how to
(0)            get other head shapes:
(0)            - To make the head a triangle, make *headaxislength* the same as *headlength*.
(0)            - To make the arrow more pointed, reduce *headwidth* or increase *headlength*
(2)              and *headaxislength*.
(0)            - To make the head smaller relative to the shaft, scale down all the head
(2)              parameters proportionally.
(0)            - To remove the head completely, set all *head* parameters to 0.
(0)            - To get a diamond-shaped head, make *headaxislength* larger than
*headlength*.
(0)            - Warning: For *headaxislength* < (*headlength* / *headwidth*), the "headaxis"
(2)              nodes (i.e. the ones connecting the head with the shaft) will protrude out
(2)              of the head in forward direction so that the arrow head looks broken.
(0)            """ % _docstring.interpd.params
(0)            _docstring.interpd.update(quiver_doc=_quiver_doc)
(0)            class QuiverKey(martist.Artist):
(4)                """Labelled arrow for use as a quiver plot scale key."""
(4)                halign = {'N': 'center', 'S': 'center', 'E': 'left', 'W': 'right'}

**kwargs):
(8)                    """
(8)                    Add a key to a quiver plot.
(8)                    The positioning of the key depends on *X*, *Y*, *coordinates*, and
(8)                    *labelpos*.  If *labelpos* is 'N' or 'S', *X*, *Y* give the position
of
(8)                    the middle of the key arrow.  If *labelpos* is 'E', *X*, *Y* positions
(8)                    the head, and if *labelpos* is 'W', *X*, *Y* positions the tail; in
(8)                    either of these two cases, *X*, *Y* is somewhere in the middle of the
(8)                    arrow+label key object.
(8)                    Parameters
(8)                    ----------
(8)                    Q : `~matplotlib.quiver.Quiver`
(12)                       A `.Quiver` object as returned by a call to `~.Axes.quiver()`.
(8)                    X, Y : float
(12)                       The location of the key.
(8)                    U : float
(12)                       The length of the key.
(8)                    label : str
(12)                       The key label (e.g., length and units of the key).
(8)                    angle : float, default: 0
(12)                       The angle of the key arrow, in degrees anti-clockwise from the
(12)                       horizontal axis.
(8)                    coordinates : {'axes', 'figure', 'data', 'inches'}, default: 'axes'
(12)                       Coordinate system and units for *X*, *Y*: 'axes' and 'figure' are
(12)                       normalized coordinate systems with (0, 0) in the lower left and
(12)                       (1, 1) in the upper right; 'data' are the axes data coordinates
(12)                       (used for the locations of the vectors in the quiver plot itself);
(12)                       'inches' is position in the figure in inches, with (0, 0) at the
(12)                       lower left corner.
(8)                    color : :mpltype:`color`
(12)                       Overrides face and edge colors from *Q*.
(8)                    labelpos : {'N', 'S', 'E', 'W'}
(12)                       Position the label above, below, to the right, to the left of the
(12)                       arrow, respectively.
```

```

(0)         _barbs_doc = r"""
(0)         Plot a 2D field of wind barbs.
(0)         Call signature::
(2)           barbs([X, Y], U, V, [C], **kwargs)
(0)         Where *X*, *Y* define the barb locations, *U*, *V* define the barb
(0)         directions, and *C* optionally sets the color.
(0)         All arguments may be 1D or 2D. *U*, *V*, *C* may be masked arrays, but masked
(0)         *X*, *Y* are not supported at present.
(0)         Barbs are traditionally used in meteorology as a way to plot the speed
(0)         and direction of wind observations, but can technically be used to
(0)         plot any two dimensional vector quantity.  As opposed to arrows, which
(0)         give vector magnitude by the length of the arrow, the barbs give more
(0)         quantitative information about the vector magnitude by putting slanted
(0)         lines or a triangle for various increments in magnitude, as show
(0)         schematically below::
(2)           :                   /\    \
(2)           :                  /  \    \
(2)           :                 /    \    \    \
(2)           :                /      \    \    \
(2)           :               ------------------------------
(0)         The largest increment is given by a triangle (or "flag"). After those
(0)         come full lines (barbs). The smallest increment is a half line.  There
(0)         is only, of course, ever at most 1 half line.  If the magnitude is
(0)         small and only needs a single half-line and no full lines or
(0)         triangles, the half-line is offset from the end of the barb so that it
(0)         can be easily distinguished from barbs with a single full line.  The
(0)         magnitude for the barb shown above would nominally be 65, using the
(0)         standard increments of 50, 10, and 5.
(0)         See also https://en.wikipedia.org/wiki/Wind_barb.
(0)         Parameters
(0)         ----------
(0)         X, Y : 1D or 2D array-like, optional
(4)             The x and y coordinates of the barb locations. See *pivot* for how the
(4)             barbs are drawn to the x, y positions.
(4)             If not given, they will be generated as a uniform integer meshgrid based
(4)             on the dimensions of *U* and *V*.
(4)             If *X* and *Y* are 1D but *U*, *V* are 2D, *X*, *Y* are expanded to 2D
(4)             using ``X, Y = np.meshgrid(X, Y)``. In this case ``len(X)`` and ``len(Y)``
(4)             must match the column and row dimensions of *U* and *V*.
(0)         U, V : 1D or 2D array-like
(4)             The x and y components of the barb shaft.
(0)         C : 1D or 2D array-like, optional
(4)             Numeric data that defines the barb colors by colormapping via *norm* and
(4)             *cmap*.
(4)             This does not support explicit colors. If you want to set colors directly,
(4)             use *barbcolor* instead.
```

```
(0)             length : float, default: 7
(4)                 Length of the barb in points; the other parts of the barb
(4)                 are scaled against this.
(0)             pivot : {'tip', 'middle'} or float, default: 'tip'
(4)                 The part of the arrow that is anchored to the *X*, *Y* grid. The barb
(4)                 rotates about this point. This can also be a number, which shifts the
(4)                 start of the barb that many points away from grid point.
(0)             barbcolor : :mpltype:`color` or color sequence
(4)                 The color of all parts of the barb except for the flags.  This parameter
(4)                 is analogous to the *edgecolor* parameter for polygons, which can be used
(4)                 instead. However this parameter will override facecolor.
(0)             flagcolor : :mpltype:`color` or color sequence
(4)                 The color of any flags on the barb.  This parameter is analogous to the
(4)                 *facecolor* parameter for polygons, which can be used instead. However,
(4)                 this parameter will override facecolor.  If this is not set (and *C* has
(4)                 not either) then *flagcolor* will be set to match *barbcolor* so that the
(4)                 barb has a uniform color. If *C* has been set, *flagcolor* has no effect.
(0)             sizes : dict, optional
(4)                 A dictionary of coefficients specifying the ratio of a given
(4)                 feature to the length of the barb. Only those values one wishes to
(4)                 override need to be included.  These features include:
(4)                 - 'spacing' - space between features (flags, full/half barbs)
(4)                 - 'height' - height (distance from shaft to top) of a flag or full barb
(4)                 - 'width' - width of a flag, twice the width of a full barb
(4)                 - 'emptybarb' - radius of the circle used for low magnitudes
(0)             fill_empty : bool, default: False
(4)                 Whether the empty barbs (circles) that are drawn should be filled with
(4)                 the flag color.  If they are not filled, the center is transparent.
(0)             rounding : bool, default: True
(4)                 Whether the vector magnitude should be rounded when allocating barb
(4)                 components.  If True, the magnitude is rounded to the nearest multiple
(4)                 of the half-barb increment.  If False, the magnitude is simply truncated
(4)                 to the next lowest multiple.
(0)             barb_increments : dict, optional
(4)                 A dictionary of increments specifying values to associate with
(4)                 different parts of the barb. Only those values one wishes to
(4)                 override need to be included.
(4)                 - 'half' - half barbs (Default is 5)
(4)                 - 'full' - full barbs (Default is 10)
(4)                 - 'flag' - flags (default is 50)
(0)             flip_barb : bool or array-like of bool, default: False
(4)                 Whether the lines and flags should point opposite to normal.
(4)                 Normal behavior is for the barbs and lines to point right (comes from wind
(4)                 barbs having these features point towards low pressure in the Northern
(4)                 Hemisphere).
(4)                 A single value is applied to all barbs. Individual barbs can be flipped by
(4)                 passing a bool array of the same size as *U* and *V*.
(0)             Returns
(0)             -------
(0)             barbs : `~matplotlib.quiver.Barbs`
(0)             Other Parameters
(0)             ----------------
(0)             data : indexable object, optional
(4)                 DATA_PARAMETER_PLACEHOLDER
(0)             **kwargs
(4)                 The barbs can further be customized using `.PolyCollection` keyword
(4)                 arguments:
(4)                 %(PolyCollection:kwdoc)s
(0)             """ % _docstring.interpd.params
(0)             _docstring.interpd.update(barbs_doc=_barbs_doc)

(8)                 Create the wind barbs.
(8)                 Parameters
(8)                 ----------
(8)                 u, v
(12)                    Components of the vector in the x and y directions, respectively.
(8)                 nflags, nbarbs, half_barb, empty_flag
(12)                    Respectively, the number of flags, number of barbs, flag for
(12)                    half a barb, and flag for empty barb, ostensibly obtained from
(12)                    :meth:`_find_tails`.
(8)                 length
(12)                    The length of the barb staff in points.
(8)                 pivot : {"tip", "middle"} or number
(12)                    The point on the barb around which the entire barb should be
(12)                    rotated.  If a number, the start of the barb is shifted by that
(12)                    many points from the origin.
(8)                 sizes : dict
(12)                    Coefficients specifying the ratio of a given feature to the length
(12)                    of the barb. These features include:
(12)                    - *spacing*: space between features (flags, full/half barbs).
(12)                    - *height*: distance from shaft of top of a flag or full barb.
(12)                    - *width*: width of a flag, twice the width of a full barb.
(12)                    - *emptybarb*: radius of the circle used for low magnitudes.
(8)                 fill_empty : bool
(12)                    Whether the circle representing an empty barb should be filled or
(12)                    not (this changes the drawing of the polygon).
(8)                 flip : list of bool
(12)                    Whether the features should be flipped to the other side of the
(12)                    barb (useful for winds in the southern hemisphere).
(8)                 Returns
(8)                 -------
(8)                 list of arrays of vertices
(12)                    Polygon vertices for each of the wind barbs.  These polygons have
(12)                    been rotated to properly align with the vector direction.

(0)     def cycler(*args, **kwargs):
(4)         """
(4)         Create a `~cycler.Cycler` object much like :func:`cycler.cycler`,
(4)         but includes input validation.
(4)         Call signatures::
```

```
(6)                 cycler(cycler)
(6)                 cycler(label=values[, label2=values2[, ...]])
(6)                 cycler(label, values)
(4)             Form 1 copies a given `~cycler.Cycler` object.
(4)             Form 2 creates a `~cycler.Cycler` which cycles over one or more
(4)             properties simultaneously. If multiple properties are given, their
(4)             value lists must have the same length.
(4)             Form 3 creates a `~cycler.Cycler` for a single property. This form
(4)             exists for compatibility with the original cycler. Its use is
(4)             discouraged in favor of the kwarg form, i.e. ``cycler(label=values)``.
(4)             Parameters
(4)             ----------
(4)             cycler : Cycler
(8)                 Copy constructor for Cycler.
(4)             label : str
(8)                 The property key. Must be a valid `.Artist` property.
(8)                 For example, 'color' or 'linestyle'. Aliases are allowed,
(8)                 such as 'c' for 'color' and 'lw' for 'linewidth'.
(4)             values : iterable
(8)                 Finite-length iterable of the property values. These values
(8)                 are validated and will raise a ValueError if invalid.
(4)             Returns
(4)             -------
(4)             Cycler
(8)                 A new :class:`~cycler.Cycler` for the given properties.
(4)             Examples
(4)             --------
(4)             Creating a cycler for a single property:
(4)             >>> c = cycler(color=['red', 'green', 'blue'])
(4)             Creating a cycler for simultaneously cycling over multiple properties
(4)             (e.g. red circle, green plus, blue cross):
(4)             >>> c = cycler(color=['red', 'green', 'blue'],
(4)             ...            marker=['o', '+', 'x'])
(4)             """

(4)                 The symmetrical logarithmic scale is logarithmic in both the
(4)                 positive and negative directions from the origin.
(4)                 Since the values close to zero tend toward infinity, there is a
(4)                 need to have a range around zero that is linear.  The parameter
(4)                 *linthresh* allows the user to specify the size of this range
(4)                 (-*linthresh*, *linthresh*).
(4)                 Parameters
(4)                 ----------
(4)                 base : float, default: 10
(8)                     The base of the logarithm.
(4)                 linthresh : float, default: 2
(8)                     Defines the range ``(-x, x)``, within which the plot is linear.
(8)                     This avoids having the plot go to infinity around zero.
(4)                 subs : sequence of int
(8)                     Where to place the subticks between each major tick.
(8)                     For example, in a log10 scale: ``[2, 3, 4, 5, 6, 7, 8, 9]`` will place
```

```
(8)                     8 logarithmically spaced minor ticks between each major tick.
(4)                 linscale : float, optional
(8)                     This allows the linear range ``(-linthresh, linthresh)`` to be
(8)                     stretched relative to the logarithmic range. Its value is the number
of
(8)                     decades to use for each half of the linear range. For example, when
(8)                     *linscale* == 1.0 (the default), the space used for the positive and
(8)                     negative halves of the linear range will be equal to one decade in
(8)                     the logarithmic range.

(4)                 """
(4)                 A quasi-logarithmic scale based on the inverse hyperbolic sine (asinh)
(4)                 For values close to zero, this is essentially a linear scale,
(4)                 but for large magnitude values (either positive or negative)
(4)                 it is asymptotically logarithmic. The transition between these
(4)                 linear and logarithmic regimes is smooth, and has no discontinuities
(4)                 in the function gradient in contrast to
(4)                 the `.SymmetricalLogScale` ("symlog") scale.
(4)                 Specifically, the transformation of an axis coordinate :math:`a` is
(4)                 :math:`a \\rightarrow a_0 \\sinh^{-1} (a / a_0)` where :math:`a_0`
(4)                 is the effective width of the linear region of the transformation.
(4)                 In that region, the transformation is
(4)                 :math:`a \\rightarrow a + \\mathcal{O}(a^3)`.
(4)                 For large values of :math:`a` the transformation behaves as
(4)                 :math:`a \\rightarrow a_0 \\, \\mathrm{sgn}(a) \\ln |a| + \\mathcal{O}
(1)`.
```

(0)  class Sankey:
(4)      """
(4)      Sankey diagram.
(6)        Sankey diagrams are a specific type of flow diagram, in which
(6)        the width of the arrows is shown proportionally to the flow
(6)        quantity.  They are typically used to visualize energy or
(6)        material or cost transfers between processes.
(6)        `Wikipedia (6/1/2011) <https://en.wikipedia.org/wiki/Sankey_diagram>`_
(4)      """
(4)      def __init__(self, ax=None, scale=1.0, unit='', format='%G', gap=0.25,
(17)                  radius=0.1, shoulder=0.03, offset=0.15, head_angle=100,
(17)                  margin=0.4, tolerance=1e-6, **kwargs):
(8)          """
(8)          Create a new Sankey instance.
(8)          The optional arguments listed below are applied to all subdiagrams so
(8)          that there is consistent alignment and formatting.
(8)          In order to draw a complex Sankey diagram, create an instance of
(8)          `Sankey` by calling it without any kwargs::
(12)             sankey = Sankey()
(8)          Then add simple Sankey sub-diagrams::
(12)             sankey.add() # 1
(12)             sankey.add() # 2
(12)             sankey.add() # n
(8)          Finally, create the full diagram::
(12)             sankey.finish()
(8)          Or, instead, simply daisy-chain those calls::
(12)             Sankey().add().add...  .add().finish()
(8)          Other Parameters
(8)          ----------------
(8)          ax : `~matplotlib.axes.Axes`
(12)             Axes onto which the data should be plotted.  If *ax* isn't
(12)             provided, new Axes will be created.
(8)          scale : float
(12)             Scaling factor for the flows.  *scale* sizes the width of the
paths
(12)             in order to maintain proper layout.  The same scale is applied to
(12)             all subdiagrams.  The value should be chosen such that the product
(12)             of the scale and the sum of the inputs is approximately 1.0 (and
(12)             the product of the scale and the sum of the outputs is
(12)             approximately -1.0).
(8)          unit : str
(12)             The physical unit associated with the flow quantities.  If *unit*
(12)             is None, then none of the quantities are labeled.
(8)          format : str or callable
(12)             A Python number formatting string or callable used to label the
(12)             flows with their quantities (i.e., a number times a unit, where
the
(12)             unit is given). If a format string is given, the label will be
(12)             ``format % quantity``. If a callable is given, it will be called
(12)             with ``quantity`` as an argument.
(8)          gap : float
(12)             Space between paths that break in/break away to/from the top or
(12)             bottom.
(8)          radius : float
(12)             Inner radius of the vertical paths.
(8)          shoulder : float
```

```
 74: (12)                        Size of the shoulders of output arrows.
 75: (8)                     offset : float
 76: (12)                        Text offset (from the dip or tip of the arrow).
 77: (8)                     head_angle : float
 78: (12)                        Angle, in degrees, of the arrow heads (and negative of the angle
of
 79: (12)                        the tails).
 80: (8)                     margin : float
 81: (12)                        Minimum space between Sankey outlines and the edge of the plot
 82: (12)                        area.
 83: (8)                     tolerance : float
 84: (12)                        Acceptable maximum of the magnitude of the sum of flows.  The
 85: (12)                        magnitude of the sum of connected flows cannot be greater than
 86: (12)                        *tolerance*.
 87: (8)                     **kwargs
 88: (12)                        Any additional keyword arguments will be passed to `add`, which
 89: (12)                        will create the first subdiagram.

(8)                 """
(8)                 Add a simple Sankey diagram with flows at the same hierarchical level.
(8)                 Parameters
(8)                 ----------
(8)                 patchlabel : str
(12)                    Label to be placed at the center of the diagram.
(12)                    Note that *label* (not *patchlabel*) can be passed as keyword
(12)                    argument to create an entry in the legend.
(8)                 flows : list of float
(12)                    Array of flow values.  By convention, inputs are positive and
(12)                    outputs are negative.
(12)                    Flows are placed along the top of the diagram from the inside out
(12)                    in order of their index within *flows*.  They are placed along the
(12)                    sides of the diagram from the top down and along the bottom from
(12)                    the outside in.
(12)                    If the sum of the inputs and outputs is
(12)                    nonzero, the discrepancy will appear as a cubic Bézier curve along
(12)                    the top and bottom edges of the trunk.
(8)                 orientations : list of {-1, 0, 1}
(12)                    List of orientations of the flows (or a single orientation to be
(12)                    used for all flows).  Valid values are 0 (inputs from
(12)                    the left, outputs to the right), 1 (from and to the top) or -1
(12)                    (from and to the bottom).
(8)                 labels : list of (str or None)
(12)                    List of labels for the flows (or a single label to be used for all
(12)                    flows).  Each label may be *None* (no label), or a labeling
string.
(12)                    If an entry is a (possibly empty) string, then the quantity for
the
(12)                    corresponding flow will be shown below the string.  However, if
(12)                    the *unit* of the main diagram is None, then quantities are never
(12)                    shown, regardless of the value of this argument.
(8)                 trunklength : float
(12)                    Length between the bases of the input and output groups (in
(12)                    data-space units).
(8)                 pathlengths : list of float
(12)                    List of lengths of the vertical arrows before break-in or after
(12)                    break-away.  If a single value is given, then it will be applied
to
(12)                    the first (inside) paths on the top and bottom, and the length of
(12)                    all other arrows will be justified accordingly.  The *pathlengths*
(12)                    are not applied to the horizontal inputs and outputs.
(8)                 prior : int
(12)                    Index of the prior diagram to which this diagram should be
(12)                    connected.
(8)                 connect : (int, int)
(12)                    A (prior, this) tuple indexing the flow of the prior diagram and
(12)                    the flow of this diagram which should be connected.  If this is
the
(12)                    first diagram or *prior* is *None*, *connect* will be ignored.
(8)                 rotation : float
(12)                    Angle of rotation of the diagram in degrees.  The interpretation
of
(12)                    the *orientations* argument will be rotated accordingly (e.g., if
(12)                    *rotation* == 90, an *orientations* entry of 1 means to/from the
(12)                    left).  *rotation* is ignored if this diagram is connected to an
(12)                    existing one (using *prior* and *connect*).
```

```
(8)                     Returns
(8)                     -------
(8)                     Sankey
(12)                        The current `.Sankey` instance.
(8)                     Other Parameters
(8)                     ----------------
(8)                     **kwargs
(11)                       Additional keyword arguments set `matplotlib.patches.PathPatch`
(11)                       properties, listed below.  For example, one may want to use
(11)                       ``fill=False`` or ``label="A legend entry"``.

15: (4)                 Draw a stacked area plot or a streamgraph.
16: (4)                 Parameters
17: (4)                 ----------
18: (4)                 x : (N,) array-like
19: (4)                 y : (M, N) array-like
20: (8)                     The data is assumed to be unstacked. Each of the following
21: (8)                     calls is legal::
22: (12)                        stackplot(x, y)           # where y has shape (M, N)
23: (12)                        stackplot(x, y1, y2, y3)  # where y1, y2, y3, y4 have length N
24: (4)                 baseline : {'zero', 'sym', 'wiggle', 'weighted_wiggle'}
25: (8)                     Method used to calculate the baseline:
26: (8)                     - ``'zero'``: Constant zero baseline, i.e. a simple stacked plot.
27: (8)                     - ``'sym'``:  Symmetric around zero and is sometimes called
28: (10)                      'ThemeRiver'.
29: (8)                     - ``'wiggle'``: Minimizes the sum of the squared slopes.
30: (8)                     - ``'weighted_wiggle'``: Does the same but weights to account for
31: (10)                      size of each layer. It is also called 'Streamgraph'-layout. More
32: (10)                      details can be found at http://leebyron.com/streamgraph/.
33: (4)                 labels : list of str, optional
34: (8)                     A sequence of labels to assign to each data series. If unspecified,
35: (8)                     then no labels will be applied to artists.
36: (4)                 colors : list of :mpltype:`color`, optional
37: (8)                     A sequence of colors to be cycled through and used to color the
stacked
38: (8)                     areas. The sequence need not be exactly the same length as the number
39: (8)                     of provided *y*, in which case the colors will repeat from the
40: (8)                     beginning.
41: (8)                     If not specified, the colors from the Axes property cycle will be
used.
42: (4)                 hatch : list of str, default: None

388: (4)                2nd-order Runge-Kutta algorithm with adaptive step size.
389: (4)                This method is also referred to as the improved Euler's method, or Heun's
390: (4)                method. This method is favored over higher-order methods because:
391: (4)                1. To get decent looking trajectories and to sample every mask cell
392: (7)                   on the trajectory we need a small timestep, so a lower order
393: (7)                   solver doesn't hurt us unless the data is *very* high resolution.
394: (7)                   In fact, for cases where the user inputs
395: (7)                   data smaller or of similar grid size to the mask grid, the higher
396: (7)                   order corrections are negligible because of the very fast linear
397: (7)                   interpolation used in `interpgrid`.
398: (4)                2. For high resolution input data (i.e. beyond the mask
399: (7)                   resolution), we must reduce the timestep. Therefore, an adaptive
400: (7)                   timestep is more suited to the problem as this would be very hard
401: (7)                   to judge automatically otherwise.
402: (4)                This integrator is about 1.5 - 2x as fast as RK4 and RK45 solvers (using
403: (4)                similar Python implementations) in most setups.

(4)                 The table consists of a grid of cells, which are indexed by (row, column).
(4)                 For a simple table, you'll have a full grid of cells with indices from
(4)                 (0, 0) to (num_rows-1, num_cols-1), in which the cell (0, 0) is positioned
(4)                 at the top left. However, you can also add cells with negative indices.
(4)                 You don't have to add a cell to every grid position, so you can create
(4)                 tables that have holes.
(4)                 *Note*: You'll usually not create an empty table from scratch. Instead use
(4)                 `~matplotlib.table.table` to create a table from data.

(12)                        of values are supported:
(12)                        - One of the following strings:
(14)                          ====================
==========================================
(14)                          Value                Description
(14)                          ====================
==========================================
(14)                          'figure points'      Points from the lower left of the figure
(14)                          'figure pixels'      Pixels from the lower left of the figure
(14)                          'figure fraction'    Fraction of figure from lower left
(14)                          'subfigure points'   Points from the lower left of the subfigure
(14)                          'subfigure pixels'   Pixels from the lower left of the subfigure
(14)                          'subfigure fraction' Fraction of subfigure from lower left
(14)                          'axes points'        Points from lower left corner of the Axes
(14)                          'axes pixels'        Pixels from lower left corner of the Axes
(14)                          'axes fraction'      Fraction of Axes from lower left
(14)                          'data'               Use the coordinate system of the object
(35)                                               being annotated (default)
(14)                          'polar'              *(theta, r)* if not native 'data'
(35)                                               coordinates
(14)                          ====================
==========================================
(14)                          Note that 'subfigure pixels' and 'figure pixels' are the same
(14)                          for the parent figure, so users who want code that is usable in
(14)                          a subfigure can use 'subfigure pixels'.
(12)                        - An `.Artist`: *xy* is interpreted as a fraction of the artist's
(14)                          `~matplotlib.transforms.Bbox`. E.g. *(0, 0)* would be the lower
(14)                          left corner of the bounding box and *(0.5, 1)* would be the
(14)                          center top of the bounding box.
(12)                        - A `.Transform` to transform *xy* to screen coordinates.
(12)                        - A function with one of the following signatures::
(16)                            def transform(renderer) -> Bbox
(16)                            def transform(renderer) -> Transform
(14)                          where *renderer* is a `.RendererBase` subclass.
(14)                          The result of the function is interpreted like the `.Artist` and
(14)                          `.Transform` cases above.
(12)                        - A tuple *(xcoords, ycoords)* specifying separate coordinate
(14)                          systems for *x* and *y*. *xcoords* and *ycoords* must each be
(14)                          of one of the above described types.
(12)                        See :ref:`plotting-guide-annotation` for more details.
(8)                     textcoords : single or two-tuple of str or `.Artist` or `.Transform` \
(0)             or callable, default: value of *xycoords*
(12)                        The coordinate system that *xytext* is given in.
(12)                        All *xycoords* values are valid as well as the following strings:
(12)                        =================
=================================================
(12)                        Value               Description
(12)                        =================
=================================================
(12)                        'offset points'     Offset, in points, from the *xy* value
(12)                        'offset pixels'     Offset, in pixels, from the *xy* value
(12)                        'offset fontsize'   Offset, relative to fontsize, from the *xy*
value
(12)                        =================
=================================================
(8)                     arrowprops : dict, optional
(12)                        The properties used to draw a `.FancyArrowPatch` arrow between the
(12)                        positions *xy* and *xytext*.  Defaults to None, i.e. no arrow is
(12)                        drawn.
(12)                        For historical reasons there are two different ways to specify
(12)                        arrows, "simple" and "fancy":
```

```
            **Simple arrow:**
            If *arrowprops* does not contain the key 'arrowstyle' the
            allowed keys are:
            ==========  ==================================================
            Key         Description
            ==========  ==================================================
            width       The width of the arrow in points
            headwidth   The width of the base of the arrow head in points
            headlength  The length of the arrow head in points
            shrink      Fraction of total length to shrink from both ends
            ?           Any `.FancyArrowPatch` property
            ==========  ==================================================
            The arrow is attached to the edge of the text box, the exact
            position (corners or centers) depending on where it's pointing to.
            **Fancy arrow:**
            This is used if 'arrowstyle' is provided in the *arrowprops*.
            Valid keys are the following `.FancyArrowPatch` parameters:
            ===============  ===================================
            Key              Description
            ===============  ===================================
            arrowstyle       The arrow style
            connectionstyle  The connection style
            relpos           See below; default is (0.5, 0.5)
            patchA           Default is bounding box of the text
            patchB           Default is None
            shrinkA          In points. Default is 2 points
            shrinkB          In points. Default is 2 points
            mutation_scale   Default is text size (in points)
            mutation_aspect  Default is 1
            ?                Any `.FancyArrowPatch` property
            ===============  ===================================
            The exact starting point position of the arrow is defined by
            *relpos*. It's a tuple of relative coordinates of the text box,
            where (0, 0) is the lower left corner and (1, 1) is the upper
            right corner. Values <0 and >1 are supported and specify points
            outside the text box. By default (0.5, 0.5), so the starting point
            is centered in the text box.
        annotation_clip : bool or None, default: None
            Whether to clip (i.e. not draw) the annotation when the annotation
            point *xy* is outside the Axes area.
            - If *True*, the annotation will be clipped when *xy* is outside
              the Axes.
            - If *False*, the annotation will always be drawn.
            - If *None*, the annotation will be clipped when *xy* is outside
              the Axes and *xycoords* is 'data'.
        **kwargs
            Additional kwargs are passed to `.Text`.
        Returns
        -------

11: (0)             Tick locating
12: (0)             -------------
13: (0)             The Locator class is the base class for all tick locators. The locators
14: (0)             handle autoscaling of the view limits based on the data limits, and the
15: (0)             choosing of tick locations. A useful semi-automatic tick locator is
16: (0)             `MultipleLocator`. It is initialized with a base, e.g., 10, and it picks
17: (0)             axis limits and ticks that are multiples of that base.
18: (0)             The Locator subclasses defined here are:
19: (0)             ========================
=======================================================
20: (0)             `AutoLocator`           `MaxNLocator` with simple defaults. This is the
default
21: (24)                                    tick locator for most plotting.
22: (0)             `MaxNLocator`           Finds up to a max number of intervals with ticks at
23: (24)                                    nice locations.
24: (0)             `LinearLocator`         Space ticks evenly from min to max.
25: (0)             `LogLocator`            Space ticks logarithmically from min to max.
26: (0)             `MultipleLocator`       Ticks and range are a multiple of base; either integer
27: (24)                                    or float.
28: (0)             `FixedLocator`          Tick locations are fixed.
29: (0)             `IndexLocator`          Locator for index plots (e.g., where
30: (24)                                    ``x = range(len(y))``).
31: (0)             `NullLocator`           No ticks.
32: (0)             `SymmetricalLogLocator` Locator for use with the symlog norm; works like
33: (24)                                    `LogLocator` for the part outside of the threshold and
34: (24)                                    adds 0 if inside the limits.
35: (0)             `AsinhLocator`          Locator for use with the asinh norm, attempting to
36: (24)                                    space ticks approximately uniformly.
37: (0)             `LogitLocator`          Locator for logit scaling.
38: (0)             `AutoMinorLocator`      Locator for minor ticks when the axis is linear and
the
39: (24)                                    major ticks are uniformly spaced. Subdivides the major
40: (24)                                    tick interval into a specified number of minor
41: (24)                                    intervals, defaulting to 4 or 5 depending on the major
42: (24)                                    interval.
43: (0)             ========================
=======================================================
44: (0)             There are a number of locators specialized for date locations - see
45: (0)             the :mod:`.dates` module.
46: (0)             You can define your own locator by deriving from Locator. You must
47: (0)             override the ``__call__`` method, which returns a sequence of locations,
48: (0)             and you will probably want to override the autoscale method to set the
49: (0)             view limits from the data limits.
50: (0)             If you want to override the default locator, use one of the above or a custom
51: (0)             locator and pass it to the x- or y-axis instance. The relevant methods are::
52: (2)               ax.xaxis.set_major_locator(xmajor_locator)
53: (2)               ax.xaxis.set_minor_locator(xminor_locator)
54: (2)               ax.yaxis.set_major_locator(ymajor_locator)
```

```
 55: (2)              ax.yaxis.set_minor_locator(yminor_locator)
 56: (0)            The default minor locator is `NullLocator`, i.e., no minor ticks on by
default.
 57: (0)            .. note::
 58: (4)                `Locator` instances should not be used with more than one
 59: (4)                `~matplotlib.axis.Axis` or `~matplotlib.axes.Axes`. So instead of::
 60: (8)                    locator = MultipleLocator(5)
 61: (8)                    ax.xaxis.set_major_locator(locator)
 62: (8)                    ax2.xaxis.set_major_locator(locator)
 63: (4)                do the following instead::
 64: (8)                    ax.xaxis.set_major_locator(MultipleLocator(5))
 65: (8)                    ax2.xaxis.set_major_locator(MultipleLocator(5))
 66: (0)            .. _formatters:
 67: (0)            Tick formatting
 68: (0)            ---------------
 69: (0)            Tick formatting is controlled by classes derived from Formatter. The formatter
 70: (0)            operates on a single tick value and returns a string to the axis.
 71: (0)            =========================
=====================================================
 72: (0)            `NullFormatter`           No labels on the ticks.
 73: (0)            `FixedFormatter`          Set the strings manually for the labels.
 74: (0)            `FuncFormatter`           User defined function sets the labels.
 75: (0)            `StrMethodFormatter`      Use string `format` method.
 76: (0)            `FormatStrFormatter`      Use an old-style sprintf format string.
 77: (0)            `ScalarFormatter`         Default formatter for scalars: autopick the format
 78: (26)                                     string.
 79: (0)            `LogFormatter`            Formatter for log axes.
 80: (0)            `LogFormatterExponent`    Format values for log axis using
 81: (26)                                     ``exponent = log_base(value)``.
 82: (0)            `LogFormatterMathtext`    Format values for log axis using
 83: (26)                                     ``exponent = log_base(value)`` using Math text.
 84: (0)            `LogFormatterSciNotation` Format values for log axis using scientific
notation.
 85: (0)            `LogitFormatter`          Probability formatter.
 86: (0)            `EngFormatter`            Format labels in engineering notation.
 87: (0)            `PercentFormatter`        Format labels as a percentage.
 88: (0)            =========================
=====================================================
 89: (0)            You can derive your own formatter from the Formatter base class by
 90: (0)            simply overriding the ``__call__`` method. The formatter class has
 91: (0)            access to the axis view and data limits.
 92: (0)            To control the major and minor tick label formats, use one of the
 93: (0)            following methods::
 94: (2)              ax.xaxis.set_major_formatter(xmajor_formatter)
 95: (2)              ax.xaxis.set_minor_formatter(xminor_formatter)
 96: (2)              ax.yaxis.set_major_formatter(ymajor_formatter)
 97: (2)              ax.yaxis.set_minor_formatter(yminor_formatter)
 98: (0)            In addition to a `.Formatter` instance, `~.Axis.set_major_formatter` and
 99: (0)            `~.Axis.set_minor_formatter` also accept a ``str`` or function.  ``str`` input
100: (0)            will be internally replaced with an autogenerated `.StrMethodFormatter` with
101: (0)            the input ``str``. For function input, a `.FuncFormatter` with the input
102: (0)            function will be generated and used.
103: (0)            See :doc:`/gallery/ticks/major_minor_demo` for an example of setting major
104: (0)            and minor ticks. See the :mod:`matplotlib.dates` module for more information
105: (0)            and examples of using date locators and formatters.
106: (0)            """

301: (4)                Format tick values as a number.
302: (4)                Parameters
303: (4)                ----------
304: (4)                useOffset : bool or float, default: :rc:`axes.formatter.useoffset`
305: (8)                    Whether to use offset notation. See `.set_useOffset`.
306: (4)                useMathText : bool, default: :rc:`axes.formatter.use_mathtext`
307: (8)                    Whether to use fancy math formatting. See `.set_useMathText`.
308: (4)                useLocale : bool, default: :rc:`axes.formatter.use_locale`.
309: (8)                    Whether to use locale settings for decimal sign and positive sign.
310: (8)                    See `.set_useLocale`.
311: (4)                Notes
312: (4)                -----
313: (4)                In addition to the parameters above, the formatting of scientific vs.
314: (4)                floating point representation can be configured via `.set_scientific`
315: (4)                and `.set_powerlimits`).
316: (4)                **Offset notation and scientific notation**
317: (4)                Offset notation and scientific notation look quite similar at first sight.
318: (4)                Both split some information from the formatted tick values and display it
319: (4)                at the end of the axis.
320: (4)                - The scientific notation splits up the order of magnitude, i.e. a
321: (6)                  multiplicative scaling factor, e.g. ``1e6``.
322: (4)                - The offset notation separates an additive constant, e.g. ``+1e6``. The
323: (6)                  offset notation label is always prefixed with a ``+`` or ``-`` sign
```

```
  and is thus distinguishable from the order of magnitude label.
The following plot with x limits ``1_000_000`` to ``1_000_010`` illustrates
the different formatting. Note the labels at the right edge of the x axis.
.. plot::
    lim = (1_000_000, 1_000_010)
    fig, (ax1, ax2, ax3) = plt.subplots(3, 1, gridspec_kw={'hspace': 2})
    ax1.set(title='offset_notation', xlim=lim)
    ax2.set(title='scientific notation', xlim=lim)
    ax2.xaxis.get_major_formatter().set_useOffset(False)
    ax3.set(title='floating point notation', xlim=lim)
    ax3.xaxis.get_major_formatter().set_useOffset(False)
    ax3.xaxis.get_major_formatter().set_scientific(False)

    Set whether to use offset notation.
    When formatting a set numbers whose value is large compared to their
    range, the formatter can separate an additive constant. This can
    shorten the formatted numbers so that they are less likely to overlap
    when drawn on an axis.
    Parameters
    ----------
    val : bool or float
        - If False, do not use offset notation.
        - If True (=automatic mode), use offset notation if it can make
          the residual numbers significantly shorter. The exact behavior
          is controlled by :rc:`axes.formatter.offset_threshold`.
        - If a number, force an offset of the given value.
    Examples
    --------
    With active offset notation, the values
    ``100_000, 100_002, 100_004, 100_006, 100_008``
    will be formatted as ``0, 2, 4, 6, 8`` plus an offset ``+1e5``, which

(0)             class LogFormatter(Formatter):
(4)                 """
(4)                 Base class for formatting ticks on a log or symlog scale.
(4)                 It may be instantiated directly, or subclassed.
(4)                 Parameters
(4)                 ----------
(4)                 base : float, default: 10.
(8)                     Base of the logarithm used in all calculations.
(4)                 labelOnlyBase : bool, default: False
(8)                     If True, label ticks only at integer powers of base.
(8)                     This is normally True for major ticks and False for
(8)                     minor ticks.
```

```
(4)                 minor_thresholds : (subset, all), default: (1, 0.4)
(8)                     If labelOnlyBase is False, these two numbers control
(8)                     the labeling of ticks that are not at integer powers of
(8)                     base; normally these are the minor ticks. The controlling
(8)                     parameter is the log of the axis data range.  In the typical
(8)                     case where base is 10 it is the number of decades spanned
(8)                     by the axis, so we can call it 'numdec'. If ``numdec <= all``,
(8)                     all minor ticks will be labeled.  If ``all < numdec <= subset``,
(8)                     then only a subset of minor ticks will be labeled, so as to
(8)                     avoid crowding. If ``numdec > subset`` then no minor ticks will
(8)                     be labeled.
(4)                 linthresh : None or float, default: None
(8)                     If a symmetric log scale is in use, its ``linthresh``
(8)                     parameter must be supplied here.
(4)                 Notes
(4)                 -----
(4)                 The `set_locs` method must be called to enable the subsetting
(4)                 logic controlled by the ``minor_thresholds`` parameter.
(4)                 In some cases such as the colorbar, there is no distinction between
(4)                 major and minor ticks; the tick locations might be set manually,
(4)                 or by a locator that puts ticks at integer powers of base and
(4)                 at intermediate locations.  For this situation, disable the
(4)                 minor_thresholds logic by using ``minor_thresholds=(np.inf, np.inf)``,
(4)                 so that all ticks will be labeled.
(4)                 To disable labeling of minor ticks when 'labelOnlyBase' is False,
(4)                 use ``minor_thresholds=(0, 0)``.  This is the default for the
(4)                 "classic" style.
(4)                 Examples
(4)                 --------
(4)                 To label a subset of minor ticks when the view limits span up
(4)                 to 2 decades, and all of the ticks when zoomed in to 0.5 decades
(4)                 or less, use ``minor_thresholds=(2, 0.5)``.
(4)                 To label all minor ticks when the view limits span up to 1.5
(4)                 decades, use ``minor_thresholds=(1.5, 1.5)``.

----------------------------------------

File 68 - transforms.py:

1: (0)              """
2: (0)              Matplotlib includes a framework for arbitrary geometric
3: (0)              transformations that is used determine the final position of all
4: (0)              elements drawn on the canvas.
5: (0)              Transforms are composed into trees of `TransformNode` objects
6: (0)              whose actual value depends on their children.  When the contents of
7: (0)              children change, their parents are automatically invalidated.  The
8: (0)              next time an invalidated transform is accessed, it is recomputed to
9: (0)              reflect those changes.  This invalidation/caching approach prevents
10: (0)             unnecessary recomputations of transforms, and contributes to better
11: (0)             interactive performance.
12: (0)             For example, here is a graph of the transform tree used to plot data
13: (0)             to the graph:
14: (0)             .. image:: ../_static/transforms.png
15: (0)             The framework can be used for both affine and non-affine
16: (0)             transformations.  However, for speed, we want to use the backend
17: (0)             renderers to perform affine transformations whenever possible.
18: (0)             Therefore, it is possible to perform just the affine or non-affine
19: (0)             part of a transformation on a set of data.  The affine is always
20: (0)             assumed to occur after the non-affine.  For any transform::
21: (2)               full transform == non-affine part + affine part
22: (0)             The backends are not expected to handle non-affine transformations
23: (0)             themselves.
24: (0)             See the tutorial :ref:`transforms_tutorial` for examples
25: (0)             of how to use transforms.
26: (0)             """

563: (4)                stand-in for the empty set.
564: (8)                    >>> Bbox.null()
565: (8)                    Bbox([[inf, inf], [-inf, -inf]])
566: (4)                Adding points to the null bbox will give you the bbox of those points.
567: (8)                    >>> box = Bbox.null()
568: (8)                    >>> box.update_from_data_xy([[1, 1]])
569: (8)                    >>> box
570: (8)                    Bbox([[1.0, 1.0], [1.0, 1.0]])
571: (8)                    >>> box.update_from_data_xy([[2, 3], [3, 2]], ignore=False)
572: (8)                    >>> box
573: (8)                    Bbox([[1.0, 1.0], [3.0, 3.0]])
574: (4)                Setting ``ignore=True`` is equivalent to starting over from a null bbox.
575: (8)                    >>> box.update_from_data_xy([[1, 1]], ignore=True)
576: (8)                    >>> box
577: (8)                    Bbox([[1.0, 1.0], [1.0, 1.0]])
578: (4)                .. warning::
579: (8)                    It is recommended to always specify ``ignore`` explicitly.  If not,
the
580: (8)                    default value of ``ignore`` can be changed at any time by code with
581: (8)                    access to your Bbox, for example using the method `~.Bbox.ignore`.
582: (4)                **Properties of the ``null`` bbox**
583: (4)                .. note::
584: (8)                    The current behavior of `Bbox.null()` may be surprising as it does
585: (8)                    not have all of the properties of the "empty set", and as such does
586: (8)                    not behave like a "zero" object in the mathematical sense. We may
```

```
(8)                 change that in the future (with a deprecation period).
(4)             The null bbox is the identity for intersections
(8)                 >>> Bbox.intersection(Bbox([[1, 1], [3, 7]]), Bbox.null())
(8)                 Bbox([[1.0, 1.0], [3.0, 7.0]])
(4)             except with itself, where it returns the full space.
(8)                 >>> Bbox.intersection(Bbox.null(), Bbox.null())
(8)                 Bbox([[-inf, -inf], [inf, inf]])
(4)             A union containing null will always return the full space (not the other
(4)             set!)
(8)                 >>> Bbox.union([Bbox([[0, 0], [0, 0]]), Bbox.null()])
(8)                 Bbox([[-inf, -inf], [inf, inf]])

(8)                     Cancellation (rather than naively returning ``A + B.inverted()``) is
(8)                     important for multiple reasons:
(8)                     - It avoids floating-point inaccuracies when computing the inverse of
(10)                      B: ``B - B`` is guaranteed to cancel out exactly (resulting in the
(10)                      identity transform), whereas ``B + B.inverted()`` may differ by a
(10)                      small epsilon.
(8)                     - ``B.inverted()`` always returns a frozen transform: if one computes
(10)                      ``A + B + B.inverted()`` and later mutates ``B``, then
(10)                      ``B.inverted()`` won't be updated and the last two terms won't
cancel
(10)                      out anymore; on the other hand, ``A + B - B`` will always be equal
to
(10)                      ``A`` even if ``B`` is mutated.
(8)                     """

(8)                     Parameters
(8)                     ----------
(8)                     ax : Axes
(12)                        The Axes to put the slider in.
(8)                     label : str
(12)                        Slider label.
(8)                     valmin : float
(12)                        The minimum value of the slider.
(8)                     valmax : float
(12)                        The maximum value of the slider.
(8)                     valinit : tuple of float or None, default: None
(12)                        The initial positions of the slider. If None the initial positions
(12)                        will be at the 25th and 75th percentiles of the range.
(8)                     valfmt : str, default: None
(12)                        %-format string used to format the slider values.  If None, a
(12)                        `.ScalarFormatter` is used instead.
(8)                     closedmin : bool, default: True
(12)                        Whether the slider interval is closed on the bottom.
(8)                     closedmax : bool, default: True
(12)                        Whether the slider interval is closed on the top.
(8)                     dragging : bool, default: True
(12)                        If True the slider can be dragged by the mouse.
(8)                     valstep : float, default: None
(12)                        If given, the slider will snap to multiples of *valstep*.
(8)                     orientation : {'horizontal', 'vertical'}, default: 'horizontal'
(12)                        The orientation of the slider.
(8)                     track_color : :mpltype:`color`, default: 'lightgrey'
(12)                        The color of the background track. The track is accessible for
(12)                        further styling via the *track* attribute.
(8)                     handle_style : dict
(12)                        Properties of the slider handles. Default values are
(12)                        ========= ===== ======= ========================================
(12)                        Key       Value Default Description
(12)                        ========= ===== ======= ========================================
(12)                        facecolor color 'white' The facecolor of the slider handles.
(12)                        edgecolor color '.75'   The edgecolor of the slider handles.
(12)                        size      int   10      The size of the slider handles in points.
(12)                        ========= ===== ======= ========================================
(12)                        Other values will be transformed as marker{foo} and passed to the
(12)                        `~.Line2D` constructor. e.g. ``handle_style = {'style'='x'}`` will
(12)                        result in ``markerstyle = 'x'``.
(8)                     Notes
(8)                     -----
(8)                     Additional kwargs are passed on to ``self.poly`` which is the
(8)                     `~matplotlib.patches.Polygon` that draws the slider knob.  See the
(8)                     `.Polygon` documentation for valid property names (``facecolor``,
(8)                     ``edgecolor``, ``alpha``, etc.).

(4)             Press and release events triggered at the same coordinates outside the
(4)             selection will clear the selector, except when
(4)             ``ignore_event_outside=True``.
(4)             Parameters
(4)             ----------
(4)             ax : `~matplotlib.axes.Axes`
(4)             onselect : callable with signature ``func(min: float, max: float)``
(8)                 A callback function that is called after a release event and the
(8)                 selection is created, changed or removed.
(4)             direction : {"horizontal", "vertical"}
(8)                 The direction along which to draw the span selector.
(4)             minspan : float, default: 0
(8)                 If selection is less than or equal to *minspan*, the selection is
(8)                 removed (when already existing) or cancelled.
(4)             useblit : bool, default: False
(8)                 If True, use the backend-dependent blitting features for faster
(8)                 canvas updates. See the tutorial :ref:`blitting` for details.
(4)             props : dict, default: {'facecolor': 'red', 'alpha': 0.5}
(8)                 Dictionary of `.Patch` properties.
```

```
(4)                onmove_callback : callable with signature ``func(min: float, max:
float)``, optional
(8)                    Called on mouse move while the span is being selected.
(4)                interactive : bool, default: False
(8)                    Whether to draw a set of handles that allow interaction with the
(8)                    widget after it is drawn.
(4)                button : `.MouseButton` or list of `.MouseButton`, default: all buttons
(8)                    The mouse buttons which activate the span selector.
(4)                handle_props : dict, default: None
(8)                    Properties of the handle lines at the edges of the span. Only used
(8)                    when *interactive* is True. See `.Line2D` for valid properties.
(4)                grab_range : float, default: 10
(8)                    Distance in pixels within which the interactive tool handles can be
activated.
(4)                state_modifier_keys : dict, optional
(8)                    Keyboard modifiers which affect the widget's behavior.  Values
(8)                    amend the defaults, which are:
(8)                    - "clear": Clear the current shape, default: "escape".
(4)                drag_from_anywhere : bool, default: False
(8)                    If `True`, the widget can be moved by clicking anywhere within its
bounds.
(4)                ignore_event_outside : bool, default: False
(8)                    If `True`, the event triggered outside the span selector will be
ignored.
(4)                snap_values : 1D array-like, optional
(8)                    Snap the selector edges to the given values.
(4)                Examples
(4)                --------
(4)                >>> import matplotlib.pyplot as plt
(4)                >>> import matplotlib.widgets as mwidgets
(4)                >>> fig, ax = plt.subplots()
(4)                >>> ax.plot([1, 2, 3], [10, 50, 100])
(4)                >>> def onselect(vmin, vmax):
(4)                ...     print(vmin, vmax)
