(0)         _RECTANGLESELECTOR_PARAMETERS_DOCSTRING = \
(4)             r"""
(4)             Parameters
(4)             ----------
(4)             ax : `~matplotlib.axes.Axes`
(8)                 The parent Axes for the widget.
(4)             onselect : function
(8)                 A callback function that is called after a release event and the
(8)                 selection is created, changed or removed.
(8)                 It must have the signature::
(12)                    def onselect(eclick: MouseEvent, erelease: MouseEvent)
(8)                 where *eclick* and *erelease* are the mouse click and release
(8)                 `.MouseEvent`\s that start and complete the selection.
(4)             minspanx : float, default: 0
(8)                 Selections with an x-span less than or equal to *minspanx* are removed
(8)                 (when already existing) or cancelled.
(4)             minspany : float, default: 0
(8)                 Selections with an y-span less than or equal to *minspanx* are removed
(8)                 (when already existing) or cancelled.
(4)             useblit : bool, default: False
(8)                 Whether to use blitting for faster drawing (if supported by the
(8)                 backend). See the tutorial :ref:`blitting`
(8)                 for details.
(4)             props : dict, optional
(8)                 Properties with which the __ARTIST_NAME__ is drawn. See
(8)                 `.Patch` for valid properties.
(8)                 Default:
(8)                 ``dict(facecolor='red', edgecolor='black', alpha=0.2, fill=True)``
(4)             spancoords : {"data", "pixels"}, default: "data"
(8)                 Whether to interpret *minspanx* and *minspany* in data or in pixel
(8)                 coordinates.
(4)             button : `.MouseButton`, list of `.MouseButton`, default: all buttons
(8)                 Button(s) that trigger rectangle selection.
(4)             grab_range : float, default: 10
(8)                 Distance in pixels within which the interactive tool handles can be
(8)                 activated.
(4)             handle_props : dict, optional
(8)                 Properties with which the interactive handles (marker artists) are
(8)                 drawn. See the marker arguments in `.Line2D` for valid
(8)                 properties.  Default values are defined in ``mpl.rcParams`` except for
(8)                 the default value of ``markeredgecolor`` which will be the same as the
(8)                 ``edgecolor`` property in *props*.
(4)             interactive : bool, default: False
(8)                 Whether to draw a set of handles that allow interaction with the
(8)                 widget after it is drawn.
(4)             state_modifier_keys : dict, optional
(8)                 Keyboard modifiers which affect the widget's behavior.  Values
(8)                 amend the defaults, which are:
(8)                 - "move": Move the existing shape, default: no modifier.
(8)                 - "clear": Clear the current shape, default: "escape".
(8)                 - "square": Make the shape square, default: "shift".
(8)                 - "center": change the shape around its center, default: "ctrl".
```

```
(8)                 - "rotate": Rotate the shape around its center between -45° and 45°,
(10)                  default: "r".
(8)                 "square" and "center" can be combined. The square shape can be defined
(8)                 in data or display coordinates as determined by the
(8)                 ``use_data_coordinates`` argument specified when creating the
selector.
(4)             drag_from_anywhere : bool, default: False
(8)                 If `True`, the widget can be moved by clicking anywhere within
(8)                 its bounds.
(4)             ignore_event_outside : bool, default: False
(8)                 If `True`, the event triggered outside the span selector will be
(8)                 ignored.
(4)             use_data_coordinates : bool, default: False
(8)                 If `True`, the "square" shape of the selector is defined in
(8)                 data coordinates instead of display coordinates.
(4)             """

class PolygonSelector(_SelectorWidget):
    """
    Select a polygon region of an Axes.
    Place vertices with each mouse click, and make the selection by completing
    the polygon (clicking on the first vertex). Once drawn individual vertices
    can be moved by clicking and dragging with the left mouse button, or
    removed by clicking the right mouse button.
    In addition, the following modifier keys can be used:
    - Hold *ctrl* and click and drag a vertex to reposition it before the
      polygon has been completed.
    - Hold the *shift* key and click and drag anywhere in the Axes to move
      all vertices.
    - Press the *esc* key to start a new polygon.
    For the selector to remain responsive you must keep a reference to it.
    Parameters
    ----------
    ax : `~matplotlib.axes.Axes`
        The parent Axes for the widget.
    onselect : function
        When a polygon is completed or modified after completion,
        the *onselect* function is called and passed a list of the vertices as
        ``(xdata, ydata)`` tuples.
    useblit : bool, default: False
        Whether to use blitting for faster drawing (if supported by the
        backend). See the tutorial :ref:`blitting`
        for details.
    props : dict, optional
        Properties with which the line is drawn, see `.Line2D` for valid
properties.
        Default::
            dict(color='k', linestyle='-', linewidth=2, alpha=0.5)
    handle_props : dict, optional
        Artist properties for the markers drawn at the vertices of the
polygon.
        See the marker arguments in `.Line2D` for valid
        properties.  Default values are defined in ``mpl.rcParams`` except for
        the default value of ``markeredgecolor`` which will be the same as the
        ``color`` property in *props*.
    grab_range : float, default: 10
        A vertex is selected (to complete the polygon or to move a vertex) if
        the mouse click is within *grab_range* pixels of the vertex.
    draw_bounding_box : bool, optional
        If `True`, a bounding box will be drawn around the polygon selector
        once it is complete. This box can be used to move and resize the
        selector.
    box_handle_props : dict, optional
        Properties to set for the box handles. See the documentation for the
        *handle_props* argument to `RectangleSelector` for more info.
    box_props : dict, optional
        Properties to set for the box. See the documentation for the *props*
        argument to `RectangleSelector` for more info.
    Examples
    --------
    :doc:`/gallery/widgets/polygon_selector_simple`
    :doc:`/gallery/widgets/polygon_selector_demo`
    Notes
    -----
    If only one point remains after removing points, the selector reverts to
an
    incomplete state and you can start drawing a new polygon from the existing
    point.

(4)             Selection curve of an arbitrary shape.
(4)             The selected path can be used in conjunction with
(4)             `~matplotlib.path.Path.contains_point` to select data points from an image.
(4)             Unlike `LassoSelector`, this must be initialized with a starting
(4)             point *xy*, and the `Lasso` events are destroyed upon release.
(4)             Parameters
(4)             ----------
(4)             ax : `~matplotlib.axes.Axes`
(8)                 The parent Axes for the widget.
(4)             xy : (float, float)
(8)                 Coordinates of the start of the lasso.
(4)             callback : callable
(8)                 Whenever the lasso is released, the *callback* function is called and
(8)                 passed the vertices of the selected path.
(4)             useblit : bool, default: True
(8)                 Whether to use blitting for faster drawing (if supported by the
(8)                 backend). See the tutorial :ref:`blitting`
(8)                 for details.
(4)             props: dict, optional
(8)                 Lasso line properties. See `.Line2D` for valid properties.
(8)                 Default *props* are::
(12)                    {'linestyle' : '-', 'color' : 'black', 'lw' : 2}
(8)                 .. versionadded:: 3.9

217: (4)                """
218: (4)                Select and call the function that accepts ``*args, **kwargs``.
219: (4)                *funcs* is a list of functions which should not raise any exception (other
220: (4)                than `TypeError` if the arguments passed do not match their signature).
221: (4)                `select_matching_signature` tries to call each of the functions in *funcs*
222: (4)                with ``*args, **kwargs`` (in the order in which they are given).  Calls
223: (4)                that fail with a `TypeError` are silently skipped.  As soon as a call
224: (4)                succeeds, `select_matching_signature` returns its return value.  If no
225: (4)                function accepts ``*args, **kwargs``, then the `TypeError` raised by the
226: (4)                last failing call is re-raised.
227: (4)                Callers should normally make sure that any ``*args, **kwargs`` can only
228: (4)                bind a single *func* (to avoid any ambiguity), although this is not
checked
229: (4)                by `select_matching_signature`.
230: (4)                Notes
231: (4)                -----
232: (4)                `select_matching_signature` is intended to help implementing
233: (4)                signature-overloaded functions.  In general, such functions should be
234: (4)                avoided, except for back-compatibility concerns.  A typical use pattern is
235: (4)                ::
236: (8)                    def my_func(*args, **kwargs):

186: (8)                    The call signatures correspond to the following different ways to use
187: (8)                    this method:
188: (8)                    **1. Automatic detection of elements to be shown in the legend**
189: (8)                    The elements to be added to the legend are automatically determined,
190: (8)                    when you do not pass in any extra arguments.
191: (8)                    In this case, the labels are taken from the artist. You can specify
192: (8)                    them either at artist creation or by calling the
193: (8)                    :meth:`~.Artist.set_label` method on the artist::
194: (12)                        ax.plot([1, 2, 3], label='Inline label')
195: (12)                        ax.legend()
196: (8)                    or::
197: (12)                        line, = ax.plot([1, 2, 3])
198: (12)                        line.set_label('Label via method')
199: (12)                        ax.legend()
200: (8)                    .. note::
201: (12)                        Specific artists can be excluded from the automatic legend element
202: (12)                        selection by using a label starting with an underscore, "_".
203: (12)                        A string starting with an underscore is the default label for all
204: (12)                        artists, so calling `.Axes.legend` without any arguments and
205: (12)                        without setting the labels manually will result in a
``UserWarning``
206: (12)                        and an empty legend being drawn.
207: (8)                    **2. Explicitly listing the artists and labels in the legend**
208: (8)                    For full control of which artists have a legend entry, it is possible
209: (8)                    to pass an iterable of legend artists followed by an iterable of
210: (8)                    legend labels respectively::
211: (12)                        ax.legend([line1, line2, line3], ['label1', 'label2', 'label3'])
212: (8)                    **3. Explicitly listing the artists in the legend**
213: (8)                    This is similar to 2, but the labels are taken from the artists'
214: (8)                    label properties. Example::
215: (12)                        line1, = ax.plot([1, 2, 3], label='label1')
216: (12)                        line2, = ax.plot([1, 2, 3], label='label2')
217: (12)                        ax.legend(handles=[line1, line2])
218: (8)                    **4. Labeling existing plot elements**
219: (8)                    .. admonition:: Discouraged
220: (12)                        This call signature is discouraged, because the relation between
221: (12)                        plot elements and labels is only implicit by their order and can
222: (12)                        easily be mixed up.
223: (8)                    To make a legend for all artists on an Axes, call this function with
224: (8)                    an iterable of strings, one for each legend item. For example::
```

```
(12)                        ax.plot([1, 2, 3])
(12)                        ax.plot([5, 6, 7])
(12)                        ax.legend(['First line', 'Second line'])
(8)                     Parameters
(8)                     ----------
(8)                     handles : list of (`.Artist` or tuple of `.Artist`), optional
(12)                        A list of Artists (lines, patches) to be added to the legend.
(12)                        Use this together with *labels*, if you need full control on what
(12)                        is shown in the legend and the automatic mechanism described above
(12)                        is not sufficient.
(12)                        The length of handles and labels should be the same in this
(12)                        case. If they are not, they are truncated to the smaller length.
(12)                        If an entry contains a tuple, then the legend handler for all
Artists in the
(12)                        tuple will be placed alongside a single label.
(8)                     labels : list of str, optional
(12)                        A list of labels to show next to the artists.
(12)                        Use this together with *handles*, if you need full control on what
(12)                        is shown in the legend and the automatic mechanism described above
(12)                        is not sufficient.
(8)                     Returns
(8)                     -------
(8)                     `~matplotlib.legend.Legend`
(8)                     Other Parameters
(8)                     ----------------
(8)                     %(_legend_kw_axes)s
(8)                     See Also
(8)                     --------
(8)                     .Figure.legend
(8)                     Notes
(8)                     -----
(8)                     Some artists are not supported by this function.  See
(8)                     :ref:`legend_guide` for details.
(8)                     Examples
(8)                     --------
(8)                     .. plot:: gallery/text_labels_and_annotations/legend.py
(8)                     """
(8)                     handles, labels, kwargs = mlegend._parse_legend_args([self], *args,
**kwargs)
(8)                     self.legend_ = mlegend.Legend(self, handles, labels, **kwargs)
(8)                     self.legend_._remove_method = self._remove_legend
(8)                     return self.legend_
(4)                 def _remove_legend(self, legend):
(8)                     self.legend_ = None
(4)                 def inset_axes(self, bounds, *, transform=None, zorder=5, **kwargs):
(8)                     """
(8)                     Add a child inset Axes to this existing Axes.
(8)                     Parameters
(8)                     ----------
(8)                     bounds : [x0, y0, width, height]
(12)                        Lower-left corner of inset Axes, and its width and height.
(8)                     transform : `.Transform`
(12)                        Defaults to `ax.transAxes`, i.e. the units of *rect* are in
(12)                        Axes-relative coordinates.
(8)                     projection : {None, 'aitoff', 'hammer', 'lambert', 'mollweide', \
(0)             'polar', 'rectilinear', str}, optional
(12)                        The projection type of the inset `~.axes.Axes`. *str* is the name
(12)                        of a custom projection, see `~matplotlib.projections`. The default
(12)                        None results in a 'rectilinear' projection.
(8)                     polar : bool, default: False
(12)                        If True, equivalent to projection='polar'.
(8)                     axes_class : subclass type of `~.axes.Axes`, optional
(12)                        The `.axes.Axes` subclass that is instantiated.  This parameter
(12)                        is incompatible with *projection* and *polar*.  See
(12)                        :ref:`axisartist_users-guide-index` for examples.
(8)                     zorder : number
(12)                        Defaults to 5 (same as `.Axes.legend`).  Adjust higher or lower
(12)                        to change whether it is above or below data plotted on the
(12)                        parent Axes.

406: (8)                    Add an inset indicator rectangle to the Axes based on the axis
407: (8)                    limits for an *inset_ax* and draw connectors between *inset_ax*
408: (8)                    and the rectangle.
409: (8)                    Warnings
410: (8)                    --------
411: (8)                    This method is experimental as of 3.0, and the API may change.
412: (8)                    Parameters
413: (8)                    ----------
414: (8)                    inset_ax : `.Axes`
415: (12)                        Inset Axes to draw connecting lines to.  Two lines are
416: (12)                        drawn connecting the indicator box to the inset Axes on corners
417: (12)                        chosen so as to not overlap with the indicator box.
418: (8)                    **kwargs
419: (12)                        Other keyword arguments are passed on to `.Axes.indicate_inset`
420: (8)                    Returns
421: (8)                    -------
422: (8)                    rectangle_patch : `.patches.Rectangle`
423: (13)                         Rectangle artist.
424: (8)                    connector_lines : 4-tuple of `.patches.ConnectionPatch`
425: (12)                        Each of four connector lines coming from the rectangle drawn on
426: (12)                        this axis, in the order lower left, upper left, lower right,
427: (12)                        upper right.
428: (12)                        Two are set with visibility to *False*,  but the user can
```

```
429: (12)                        set the visibility to *True* if the automatic choice is not deemed
430: (12)                        correct.
431: (8)                    """

508: (8)                    Add the text *s* to the Axes at location *x*, *y* in data coordinates,
509: (8)                    with a default ``horizontalalignment`` on the ``left`` and
510: (8)                    ``verticalalignment`` at the ``baseline``. See
511: (8)                    :doc:`/gallery/text_labels_and_annotations/text_alignment`.
512: (8)                    Parameters
513: (8)                    ----------
514: (8)                    x, y : float
515: (12)                       The position to place the text. By default, this is in data
516: (12)                       coordinates. The coordinate system can be changed using the
517: (12)                       *transform* parameter.
518: (8)                    s : str
519: (12)                       The text.
520: (8)                    fontdict : dict, default: None
521: (12)                       .. admonition:: Discouraged
522: (15)                          The use of *fontdict* is discouraged. Parameters should be
passed as
523: (15)                          individual keyword arguments or using dictionary-unpacking
524: (15)                          ``text(..., **fontdict)``.
525: (12)                       A dictionary to override the default text properties. If fontdict
526: (12)                       is None, the defaults are determined by `.rcParams`.
527: (8)                    Returns
528: (8)                    -------
529: (8)                    `.Text`
530: (12)                       The created `.Text` instance.
531: (8)                    Other Parameters
532: (8)                    ----------------
533: (8)                    **kwargs : `~matplotlib.text.Text` properties.
534: (12)                       Other miscellaneous text parameters.
535: (12)                       %(Text:kwdoc)s
536: (8)                    Examples
537: (8)                    --------
538: (8)                    Individual keyword arguments can be used to override any given
539: (8)                    parameter::
540: (12)                       >>> text(x, y, s, fontsize=12)
541: (8)                    The default transform specifies that text is in data coords,
542: (8)                    alternatively, you can specify text in axis coords ((0, 0) is
543: (8)                    lower-left and (1, 1) is upper-right).  The example below places
544: (8)                    text in the center of the Axes::
545: (12)                       >>> text(0.5, 0.5, 'matplotlib', horizontalalignment='center',
546: (12)                       ...      verticalalignment='center', transform=ax.transAxes)
547: (8)                    You can put a rectangular box around the text instance (e.g., to
548: (8)                    set a background color) by using the keyword *bbox*.  *bbox* is
549: (8)                    a dictionary of `~matplotlib.patches.Rectangle`
550: (8)                    properties.  For example::
551: (12)                       >>> text(x, y, s, bbox=dict(facecolor='red', alpha=0.5))
552: (8)                    """
553: (8)                    effective_kwargs = {
554: (12)                       'verticalalignment': 'baseline',
555: (12)                       'horizontalalignment': 'left',
556: (12)                       'transform': self.transData,

(4)                 def axline(self, xy1, xy2=None, *, slope=None, **kwargs):
(8)                     """
(8)                     Add an infinitely long straight line.
(8)                     The line can be defined either by two points *xy1* and *xy2*, or
(8)                     by one point *xy1* and a *slope*.
(8)                     This draws a straight line "on the screen", regardless of the x and y
(8)                     scales, and is thus also suitable for drawing exponential decays in
(8)                     semilog plots, power laws in loglog plots, etc. However, *slope*
```

```
(8)                     should only be used with linear scales; It has no clear meaning for
(8)                     all other scales, and thus the behavior is undefined. Please specify
(8)                     the line using the points *xy1*, *xy2* for non-linear scales.
(8)                     The *transform* keyword argument only applies to the points *xy1*,
(8)                     *xy2*. The *slope* (if given) is always in data coordinates. This can
(8)                     be used e.g. with ``ax.transAxes`` for drawing grid lines with a fixed
(8)                     slope.
(8)                     Parameters
(8)                     ----------
(8)                     xy1, xy2 : (float, float)
(12)                        Points for the line to pass through.
(12)                        Either *xy2* or *slope* has to be given.
(8)                     slope : float, optional
(12)                        The slope of the line. Either *xy2* or *slope* has to be given.
(8)                     Returns
(8)                     -------
(8)                     `.AxLine`
(8)                     Other Parameters

986: (8)                    neural events, where it is usually called a spike raster, dot raster,
987: (8)                    or raster plot.
988: (8)                    However, it is useful in any situation where you wish to show the
989: (8)                    timing or position of multiple sets of discrete events, such as the
990: (8)                    arrival times of people to a business on each day of the month or the
991: (8)                    date of hurricanes each year of the last century.
992: (8)                    Parameters
993: (8)                    ----------
994: (8)                    positions : array-like or list of array-like
995: (12)                       A 1D array-like defines the positions of one sequence of events.
996: (12)                       Multiple groups of events may be passed as a list of array-likes.
997: (12)                       Each group can be styled independently by passing lists of values
998: (12)                       to *lineoffsets*, *linelengths*, *linewidths*, *colors* and
999: (12)                       *linestyles*.
1000: (12)                      Note that *positions* can be a 2D array, but in practice different
1001: (12)                      event groups usually have different counts so that one will use a
1002: (12)                      list of different-length arrays rather than a 2D array.
1003: (8)                   orientation : {'horizontal', 'vertical'}, default: 'horizontal'
1004: (12)                      The direction of the event sequence:
1005: (12)                      - 'horizontal': the events are arranged horizontally.
1006: (14)                        The indicator lines are vertical.
1007: (12)                      - 'vertical': the events are arranged vertically.
1008: (14)                        The indicator lines are horizontal.
1009: (8)                   lineoffsets : float or array-like, default: 1
1010: (12)                      The offset of the center of the lines from the origin, in the
1011: (12)                      direction orthogonal to *orientation*.
1012: (12)                      If *positions* is 2D, this can be a sequence with length matching
1013: (12)                      the length of *positions*.
1014: (8)                   linelengths : float or array-like, default: 1
1015: (12)                      The total height of the lines (i.e. the lines stretches from
1016: (12)                      ``lineoffset - linelength/2`` to ``lineoffset + linelength/2``).
1017: (12)                      If *positions* is 2D, this can be a sequence with length matching
1018: (12)                      the length of *positions*.
1019: (8)                   linewidths : float or array-like, default: :rc:`lines.linewidth`
1020: (12)                      The line width(s) of the event lines, in points.
1021: (12)                      If *positions* is 2D, this can be a sequence with length matching
1022: (12)                      the length of *positions*.
1023: (8)                   colors : :mpltype:`color` or list of color, default: :rc:`lines.color`
1024: (12)                      The color(s) of the event lines.
1025: (12)                      If *positions* is 2D, this can be a sequence with length matching
1026: (12)                      the length of *positions*.
1027: (8)                   alpha : float or array-like, default: 1
1028: (12)                      The alpha blending value(s), between 0 (transparent) and 1
1029: (12)                      (opaque).
1030: (12)                      If *positions* is 2D, this can be a sequence with length matching
1031: (12)                      the length of *positions*.
1032: (8)                   linestyles : str or tuple or list of such values, default: 'solid'
```

```
(12)                        Default is 'solid'. Valid strings are ['solid', 'dashed',
(12)                        'dashdot', 'dotted', '-', '--', '-.', ':']. Dash tuples
(12)                        should be of the form::
(16)                            (offset, onoffseq),
(12)                        where *onoffseq* is an even length tuple of on and off ink
(12)                        in points.
(12)                        If *positions* is 2D, this can be a sequence with length matching
(12)                        the length of *positions*.
(8)                     data : indexable object, optional
(12)                        DATA_PARAMETER_PLACEHOLDER
(8)                     **kwargs
(12)                        Other keyword arguments are line collection properties.  See
(12)                        `.LineCollection` for a list of the valid properties.
(8)                     Returns
(8)                     -------
(8)                     list of `.EventCollection`
(12)                        The `.EventCollection` that were added.
(8)                     Notes
(8)                     -----
(8)                     For *linelengths*, *linewidths*, *colors*, *alpha* and *linestyles*,
if
(8)                     only a single value is given, that value is applied to all lines. If
an
(8)                     array-like is given, it must have the same length as *positions*, and
(8)                     each value will be applied to the corresponding row of the array.
(8)                     Examples
(8)                     --------
(8)                     .. plot:: gallery/lines_bars_and_markers/eventplot_demo.py

```
        return colls
    @_docstring.dedent_interpd
    def plot(self, *args, scalex=True, scaley=True, data=None, **kwargs):
        """
        Plot y versus x as lines and/or markers.
        Call signatures::
            plot([x], y, [fmt], *, data=None, **kwargs)
            plot([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
        The coordinates of the points or line nodes are given by *x*, *y*.
        The optional parameter *fmt* is a convenient way for defining basic
        formatting like color, marker and linestyle. It's a shortcut string
        notation described in the *Notes* section below.
        >>> plot(x, y)        # plot x and y using default line style and
color
        >>> plot(x, y, 'bo')  # plot x and y using blue circle markers
        >>> plot(y)           # plot y using x as index array 0..N-1
        >>> plot(y, 'r+')     # ditto, but with red plusses
        You can use `.Line2D` properties as keyword arguments for more
        control on the appearance. Line properties and *fmt* can be mixed.
        The following two calls yield identical results:
        >>> plot(x, y, 'go--', linewidth=2, markersize=12)
        >>> plot(x, y, color='green', marker='o', linestyle='dashed',
        ...      linewidth=2, markersize=12)
        When conflicting with *fmt*, keyword arguments take precedence.
        **Plotting labelled data**
        There's a convenient way for plotting objects with labelled data (i.e.
        data that can be accessed by index ``obj['y']``). Instead of giving
        the data in *x* and *y*, you can provide the object in the *data*
        parameter and just give the labels for *x* and *y*::
        >>> plot('xlabel', 'ylabel', data=obj)
        All indexable objects are supported. This could e.g. be a `dict`, a
        `pandas.DataFrame` or a structured numpy array.
        **Plotting multiple sets of data**
        There are various ways to plot multiple sets of data.
        - The most straight forward way is just to call `plot` multiple times.
          Example:
          >>> plot(x1, y1, 'bo')
          >>> plot(x2, y2, 'go')
        - If *x* and/or *y* are 2D arrays, a separate data set will be drawn
          for every column. If both *x* and *y* are 2D, they must have the
          same shape. If only one of them is 2D with shape (N, m) the other
          must have length N and will be used for every data set m.
          Example:
          >>> x = [1, 2, 3]
          >>> y = np.array([[1, 2], [3, 4], [5, 6]])
          >>> plot(x, y)
          is equivalent to:
          >>> for col in range(y.shape[1]):
          ...     plot(x, y[:, col])
        - The third way is to specify multiple sets of *[x]*, *y*, *[fmt]*
          groups::
          >>> plot(x1, y1, 'g^', x2, y2, 'g-')
          In this case, any additional keyword argument applies to all
          datasets. Also, this syntax cannot be combined with the *data*
          parameter.
        By default, each line is assigned a different style specified by a
        'style cycle'. The *fmt* and line property parameters are only
        necessary if you want explicit deviations from these defaults.
        Alternatively, you can also change the style cycle using
        :rc:`axes.prop_cycle`.
        Parameters
        ----------
        x, y : array-like or scalar
            The horizontal / vertical coordinates of the data points.
            *x* values are optional and default to ``range(len(y))``.
            Commonly, these parameters are 1D arrays.
            They can also be scalars, or two-dimensional (in that case, the
            columns represent separate data sets).
            These arguments cannot be passed as keywords.
```

```
(8)                 fmt : str, optional
(12)                    A format string, e.g. 'ro' for red circles. See the *Notes*
(12)                    section for a full description of the format strings.
(12)                    Format strings are just an abbreviation for quickly setting
(12)                    basic line properties. All of these and more can also be
(12)                    controlled by keyword arguments.
(12)                    This argument cannot be passed as keyword.
(8)                 data : indexable object, optional
(12)                    An object with labelled data. If given, provide the label names to
(12)                    plot in *x* and *y*.
(12)                    .. note::
(16)                        Technically there's a slight ambiguity in calls where the
(16)                        second label is a valid *fmt*. ``plot('n', 'o', data=obj)``
(16)                        could be ``plt(x, y)`` or ``plt(y, fmt)``. In such cases,
(16)                        the former interpretation is chosen, but a warning is issued.
(16)                        You may suppress the warning by adding an empty format string
(16)                        ``plot('n', 'o', '', data=obj)``.
(8)                 Returns
(8)                 -------
(8)                 list of `.Line2D`
(12)                    A list of lines representing the plotted data.
(8)                 Other Parameters
(8)                 ----------------
(8)                 scalex, scaley : bool, default: True
(12)                    These parameters determine if the view limits are adapted to the
(12)                    data limits. The values are passed on to
(12)                    `~.axes.Axes.autoscale_view`.
(8)                 **kwargs : `~matplotlib.lines.Line2D` properties, optional
(12)                    *kwargs* are used to specify properties like a line label (for
(12)                    auto legends), linewidth, antialiasing, marker face color.
(12)                    Example::
(12)                    >>> plot([1, 2, 3], [1, 2, 3], 'go-', label='line 1', linewidth=2)
(12)                    >>> plot([1, 2, 3], [1, 4, 9], 'rs', label='line 2')
(12)                    If you specify multiple lines with one plot call, the kwargs apply
(12)                    to all those lines. In case the label object is iterable, each
(12)                    element is used as labels for each set of data.
(12)                    Here is a list of available `.Line2D` properties:
(12)                    %(Line2D:kwdoc)s
(8)                 See Also
(8)                 --------
(8)                 scatter : XY scatter plot with markers of varying size and/or color (
(12)                    sometimes also called bubble chart).
(8)                 Notes
(8)                 -----
(8)                 **Format Strings**
(8)                 A format string consists of a part for color, marker and line::
(12)                    fmt = '[marker][line][color]'
(8)                 Each of them is optional. If not provided, the value from the style
(8)                 cycle is used. Exception: If ``line`` is given, but no ``marker``,
(8)                 the data will be a line without markers.
(8)                 Other combinations such as ``[color][marker][line]`` are also
(8)                 supported, but note that their parsing may be ambiguous.
(8)                 **Markers**
(8)                 =============   ==============================
(8)                 character       description
(8)                 =============   ==============================
(8)                 ``'.'``         point marker
(8)                 ``','``         pixel marker
(8)                 ``'o'``         circle marker
(8)                 ``'v'``         triangle_down marker
(8)                 ``'^'``         triangle_up marker
(8)                 ``'<'``         triangle_left marker
(8)                 ``'>'``         triangle_right marker
(8)                 ``'1'``         tri_down marker
(8)                 ``'2'``         tri_up marker
(8)                 ``'3'``         tri_left marker
(8)                 ``'4'``         tri_right marker
(8)                 ``'8'``         octagon marker
(8)                 ``'s'``         square marker
```

```
1306: (8)                    ``'p'``         pentagon marker
1307: (8)                    ``'P'``         plus (filled) marker
1308: (8)                    ``'*'``         star marker
1309: (8)                    ``'h'``         hexagon1 marker
1310: (8)                    ``'H'``         hexagon2 marker
1311: (8)                    ``'+'``         plus marker
1312: (8)                    ``'x'``         x marker
1313: (8)                    ``'X'``         x (filled) marker
1314: (8)                    ``'D'``         diamond marker
1315: (8)                    ``'d'``         thin_diamond marker
1316: (8)                    ``'|'``         vline marker
1317: (8)                    ``'_'``         hline marker
1318: (8)                    =============   ==============================
1319: (8)                    **Line Styles**
1320: (8)                    =============    ==============================
1321: (8)                    character        description
1322: (8)                    =============    ==============================

1365: (4)                def plot_date(self, x, y, fmt='o', tz=None, xdate=True, ydate=False,
1366: (18)                              **kwargs):
1367: (8)                    """
1368: (8)                    Plot coercing the axis to treat floats as dates.
1369: (8)                    .. deprecated:: 3.9
1370: (12)                       This method exists for historic reasons and will be removed in
version 3.11.
1371: (12)                       - ``datetime``-like data should directly be plotted using
1372: (14)                         `~.Axes.plot`.
1373: (12)                       -  If you need to plot plain numeric data as :ref:`date-format` or
```

```
(15)                        need to set a timezone, call ``ax.xaxis.axis_date`` /
(15)                        ``ax.yaxis.axis_date`` before `~.Axes.plot`. See
(15)                        `.Axis.axis_date`.
(8)                     Similar to `.plot`, this plots *y* vs. *x* as lines or markers.
(8)                     However, the axis labels are formatted as dates depending on *xdate*
(8)                     and *ydate*.  Note that `.plot` will work with `datetime` and
(8)                     `numpy.datetime64` objects without resorting to this method.
(8)                     Parameters
(8)                     ----------
(8)                     x, y : array-like
(12)                        The coordinates of the data points. If *xdate* or *ydate* is
(12)                        *True*, the respective values *x* or *y* are interpreted as
(12)                        :ref:`Matplotlib dates <date-format>`.
(8)                     fmt : str, optional
(12)                        The plot format string. For details, see the corresponding
(12)                        parameter in `.plot`.
(8)                     tz : timezone string or `datetime.tzinfo`, default: :rc:`timezone`
(12)                        The time zone to use in labeling dates.
(8)                     xdate : bool, default: True
(12)                        If *True*, the *x*-axis will be interpreted as Matplotlib dates.
(8)                     ydate : bool, default: False
(12)                        If *True*, the *y*-axis will be interpreted as Matplotlib dates.
(8)                     Returns
(8)                     -------
(8)                     list of `.Line2D`
(12)                        Objects representing the plotted data.
(8)                     Other Parameters
(8)                     ----------------
(8)                     data : indexable object, optional
(12)                        DATA_PARAMETER_PLACEHOLDER
(8)                     **kwargs
(12)                        Keyword arguments control the `.Line2D` properties:
(12)                        %(Line2D:kwdoc)s
(8)                     See Also
(8)                     --------
(8)                     matplotlib.dates : Helper functions on dates.
(8)                     matplotlib.dates.date2num : Convert dates to num.
(8)                     matplotlib.dates.num2date : Convert num to dates.
(8)                     matplotlib.dates.drange : Create an equally spaced sequence of dates.
(8)                     Notes
(8)                     -----
(8)                     If you are using custom date tickers and formatters, it may be
(8)                     necessary to set the formatters/locators after the call to
(8)                     `.plot_date`. `.plot_date` will set the default tick locator to
(8)                     `.AutoDateLocator` (if the tick locator is not already set to a
(8)                     `.DateLocator` instance) and the default tick formatter to
(8)                     `.AutoDateFormatter` (if the tick formatter is not already set to a
(8)                     `.DateFormatter` instance).
(8)                     """
(8)                     if xdate:
(12)                        self.xaxis_date(tz)
(8)                     if ydate:
(12)                        self.yaxis_date(tz)
(8)                     return self.plot(x, y, fmt, **kwargs)
(4)                 @_docstring.dedent_interpd
(4)                 def loglog(self, *args, **kwargs):
(8)                     """
(8)                     Make a plot with log scaling on both the x- and y-axis.
(8)                     Call signatures::
(12)                        loglog([x], y, [fmt], data=None, **kwargs)
(12)                        loglog([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
(8)                     This is just a thin wrapper around `.plot` which additionally changes
(8)                     both the x-axis and the y-axis to log scaling. All the concepts and
(8)                     parameters of plot can be used here as well.
(8)                     The additional parameters *base*, *subs* and *nonpositive* control the
(8)                     x/y-axis properties. They are just forwarded to `.Axes.set_xscale` and
(8)                     `.Axes.set_yscale`. To use different properties on the x-axis and the
(8)                     y-axis, use e.g.
(8)                     ``ax.set_xscale("log", base=10); ax.set_yscale("log", base=2)``.
```

```
(8)                     Parameters
(8)                     ----------
(8)                     base : float, default: 10
(12)                        Base of the logarithm.
(8)                     subs : sequence, optional
(12)                        The location of the minor ticks. If *None*, reasonable locations
(12)                        are automatically chosen depending on the number of decades in the
(12)                        plot. See `.Axes.set_xscale`/`.Axes.set_yscale` for details.
(8)                     nonpositive : {'mask', 'clip'}, default: 'clip'
(12)                        Non-positive values can be masked as invalid, or clipped to a very
(12)                        small positive number.
(8)                     **kwargs
(12)                        All parameters supported by `.plot`.
(8)                     Returns
(8)                     -------
(8)                     list of `.Line2D`
(12)                        Objects representing the plotted data.
(8)                     """
(8)                     dx = {k: v for k, v in kwargs.items()
(14)                          if k in ['base', 'subs', 'nonpositive',
(23)                                   'basex', 'subsx', 'nonposx']}
(8)                     self.set_xscale('log', **dx)
(8)                     dy = {k: v for k, v in kwargs.items()
(14)                          if k in ['base', 'subs', 'nonpositive',

1689: (8)                   Make a step plot.
1690: (8)                   Call signatures::
1691: (12)                      step(x, y, [fmt], *, data=None, where='pre', **kwargs)
1692: (12)                      step(x, y, [fmt], x2, y2, [fmt2], ..., *, where='pre', **kwargs)
1693: (8)                   This is just a thin wrapper around `.plot` which changes some
1694: (8)                   formatting options. Most of the concepts and parameters of plot can be
1695: (8)                   used here as well.
1696: (8)                   .. note::
1697: (12)                      This method uses a standard plot with a step drawstyle: The *x*
1698: (12)                      values are the reference positions and steps extend
left/right/both
1699: (12)                      directions depending on *where*.
1700: (12)                      For the common case where you know the values and edges of the
1701: (12)                      steps, use `~.Axes.stairs` instead.
1702: (8)                   Parameters
1703: (8)                   ----------
1704: (8)                   x : array-like
1705: (12)                      1D sequence of x positions. It is assumed, but not checked, that
1706: (12)                      it is uniformly increasing.
1707: (8)                   y : array-like
1708: (12)                      1D sequence of y levels.
1709: (8)                   fmt : str, optional
1710: (12)                      A format string, e.g. 'g' for a green line. See `.plot` for a more
1711: (12)                      detailed description.
1712: (12)                      Note: While full format strings are accepted, it is recommended to
1713: (12)                      only specify the color. Line styles are currently ignored (use
```

```
(12)                        the keyword argument *linestyle* instead). Markers are accepted
(12)                        and plotted on the given positions, however, this is a rarely
(12)                        needed feature for step plots.
(8)                     where : {'pre', 'post', 'mid'}, default: 'pre'
(12)                        Define where the steps should be placed:
(12)                        - 'pre': The y value is continued constantly to the left from
(14)                          every *x* position, i.e. the interval ``(x[i-1], x[i]]`` has the
(14)                          value ``y[i]``.
(12)                        - 'post': The y value is continued constantly to the right from
(14)                          every *x* position, i.e. the interval ``[x[i], x[i+1])`` has the
(14)                          value ``y[i]``.
(12)                        - 'mid': Steps occur half-way between the *x* positions.
(8)                     data : indexable object, optional
(12)                        An object with labelled data. If given, provide the label names to
(12)                        plot in *x* and *y*.
(8)                     **kwargs
(12)                        Additional parameters are the same as those for `.plot`.
(8)                     Returns
(8)                     -------
(8)                     list of `.Line2D`
(12)                        Objects representing the plotted data.
(8)                     """

(8)                     r"""
(8)                     Make a bar plot.
(8)                     The bars are positioned at *x* with the given *align*\ment. Their
(8)                     dimensions are given by *height* and *width*. The vertical baseline
(8)                     is *bottom* (default 0).
(8)                     Many parameters can take either a single value applying to all bars
(8)                     or a sequence of values, one for each bar.
(8)                     Parameters
(8)                     ----------
```

```
                    x : float or array-like
                        The x coordinates of the bars. See also *align* for the
                        alignment of the bars to the coordinates.
                    height : float or array-like
                        The height(s) of the bars.
                        Note that if *bottom* has units (e.g. datetime), *height* should be in
                        units that are a difference from the value of *bottom* (e.g. timedelta).
                    width : float or array-like, default: 0.8
                        The width(s) of the bars.
                        Note that if *x* has units (e.g. datetime), then *width* should be in
                        units that are a difference (e.g. timedelta) around the *x* values.
                    bottom : float or array-like, default: 0
                        The y coordinate(s) of the bottom side(s) of the bars.
                        Note that if *bottom* has units, then the y-axis will get a Locator and
                        Formatter appropriate for the units (e.g. dates, or categorical).
                    align : {'center', 'edge'}, default: 'center'
                        Alignment of the bars to the *x* coordinates:
                        - 'center': Center the base on the *x* positions.
                        - 'edge': Align the left edges of the bars with the *x* positions.
                        To align the bars on the right edge pass a negative *width* and
                        ``align='edge'``.
                    Returns
                    -------
                    `.BarContainer`
                        Container with all the bars and optionally errorbars.
                    Other Parameters
                    ----------------
                    color : :mpltype:`color` or list of :mpltype:`color`, optional
                        The colors of the bar faces.
                    edgecolor : :mpltype:`color` or list of :mpltype:`color`, optional
                        The colors of the bar edges.
                    linewidth : float or array-like, optional
                        Width of the bar edge(s). If 0, don't draw edges.
                    tick_label : str or list of str, optional
                        The tick labels of the bars.
                        Default: None (Use default numeric labels.)
                    label : str or list of str, optional
                        A single label is attached to the resulting `.BarContainer` as a
                        label for the whole dataset.
                        If a list is provided, it must be the same length as *x* and
                        labels the individual bars. Repeated labels are not de-duplicated
                        and will cause repeated label entries, so this is best used when
                        bars also differ in style (e.g., by passing a list to *color*.)
                    xerr, yerr : float or array-like of shape(N,) or shape(2, N), optional
                        If not *None*, add horizontal / vertical errorbars to the bar tips.
                        The values are +/- sizes relative to the data:
                        - scalar: symmetric +/- values for all bars
                        - shape(N,): symmetric +/- values for each bar
                        - shape(2, N): Separate - and + values for each bar. First row
                          contains the lower errors, the second row contains the upper
                          errors.
                        - *None*: No errorbar. (Default)
                        See :doc:`/gallery/statistics/errorbar_features` for an example on
                        the usage of *xerr* and *yerr*.
                    ecolor : :mpltype:`color` or list of :mpltype:`color`, default: 'black'
                        The line color of the errorbars.
                    capsize : float, default: :rc:`errorbar.capsize`
                       The length of the error bar caps in points.
                    error_kw : dict, optional
                        Dictionary of keyword arguments to be passed to the
                        `~.Axes.errorbar` method. Values of *ecolor* or *capsize* defined
                        here take precedence over the independent keyword arguments.

2013: (8)                    The bars are positioned at *y* with the given *align*\ment. Their
2014: (8)                    dimensions are given by *width* and *height*. The horizontal baseline
2015: (8)                    is *left* (default 0).
2016: (8)                    Many parameters can take either a single value applying to all bars
2017: (8)                    or a sequence of values, one for each bar.
2018: (8)                    Parameters
2019: (8)                    ----------
2020: (8)                    y : float or array-like
2021: (12)                       The y coordinates of the bars. See also *align* for the
2022: (12)                       alignment of the bars to the coordinates.
2023: (8)                    width : float or array-like
2024: (12)                       The width(s) of the bars.
2025: (12)                       Note that if *left* has units (e.g. datetime), *width* should be
in
2026: (12)                       units that are a difference from the value of *left* (e.g.
timedelta).
2027: (8)                    height : float or array-like, default: 0.8
2028: (12)                       The heights of the bars.
2029: (12)                       Note that if *y* has units (e.g. datetime), then *height* should
be in
2030: (12)                       units that are a difference (e.g. timedelta) around the *y*
values.
2031: (8)                    left : float or array-like, default: 0
2032: (12)                       The x coordinates of the left side(s) of the bars.
2033: (12)                       Note that if *left* has units, then the x-axis will get a Locator
and
2034: (12)                       Formatter appropriate for the units (e.g. dates, or categorical).
2035: (8)                    align : {'center', 'edge'}, default: 'center'
2036: (12)                       Alignment of the base to the *y* coordinates*:
2037: (12)                       - 'center': Center the bars on the *y* positions.
2038: (12)                       - 'edge': Align the bottom edges of the bars with the *y*
2039: (14)                         positions.
2040: (12)                       To align the bars on the top edge pass a negative *height* and
2041: (12)                       ``align='edge'``.
2042: (8)                    Returns
2043: (8)                    -------
2044: (8)                    `.BarContainer`
2045: (12)                       Container with all the bars and optionally errorbars.
```

```
2046: (8)                    Other Parameters
2047: (8)                    ----------------
2048: (8)                    color : :mpltype:`color` or list of :mpltype:`color`, optional
2049: (12)                       The colors of the bar faces.
2050: (8)                    edgecolor : :mpltype:`color` or list of :mpltype:`color`, optional
2051: (12)                       The colors of the bar edges.
2052: (8)                    linewidth : float or array-like, optional
2053: (12)                       Width of the bar edge(s). If 0, don't draw edges.
2054: (8)                    tick_label : str or list of str, optional
2055: (12)                       The tick labels of the bars.
2056: (12)                       Default: None (Use default numeric labels.)
2057: (8)                    label : str or list of str, optional
2058: (12)                       A single label is attached to the resulting `.BarContainer` as a
2059: (12)                       label for the whole dataset.
2060: (12)                       If a list is provided, it must be the same length as *y* and
2061: (12)                       labels the individual bars. Repeated labels are not de-duplicated
2062: (12)                       and will cause repeated label entries, so this is best used when
2063: (12)                       bars also differ in style (e.g., by passing a list to *color*.)
2064: (8)                    xerr, yerr : float or array-like of shape(N,) or shape(2, N), optional
2065: (12)                       If not *None*, add horizontal / vertical errorbars to the bar
tips.
2066: (12)                       The values are +/- sizes relative to the data:
2067: (12)                       - scalar: symmetric +/- values for all bars
2068: (12)                       - shape(N,): symmetric +/- values for each bar
2069: (12)                       - shape(2, N): Separate - and + values for each bar. First row
2070: (14)                         contains the lower errors, the second row contains the upper
2071: (14)                         errors.
2072: (12)                       - *None*: No errorbar. (default)
2073: (12)                       See :doc:`/gallery/statistics/errorbar_features` for an example on
2074: (12)                       the usage of *xerr* and *yerr*.
2075: (8)                    ecolor : :mpltype:`color` or list of :mpltype:`color`, default:
'black'
2076: (12)                       The line color of the errorbars.
2077: (8)                    capsize : float, default: :rc:`errorbar.capsize`
2078: (11)                      The length of the error bar caps in points.
2079: (8)                    error_kw : dict, optional
2080: (12)                       Dictionary of keyword arguments to be passed to the
2081: (12)                       `~.Axes.errorbar` method. Values of *ecolor* or *capsize* defined
2082: (12)                       here take precedence over the independent keyword arguments.
2083: (8)                    log : bool, default: False
2084: (12)                       If ``True``, set the x-axis to be log scale.
2085: (8)                    data : indexable object, optional
2086: (12)                       If given, all parameters also accept a string ``s``, which is
2087: (12)                       interpreted as ``data[s]`` (unless this raises an exception).
2088: (8)                    **kwargs : `.Rectangle` properties

2105: (8)                    """
2106: (8)                    Label a bar plot.
2107: (8)                    Adds labels to bars in the given `.BarContainer`.
2108: (8)                    You may need to adjust the axis limits to fit the labels.
2109: (8)                    Parameters
2110: (8)                    ----------
```

```
(8)                     container : `.BarContainer`
(12)                        Container with all the bars and optionally errorbars, likely
(12)                        returned from `.bar` or `.barh`.
(8)                     labels : array-like, optional
(12)                        A list of label texts, that should be displayed. If not given, the
(12)                        label texts will be the data values formatted with *fmt*.
(8)                     fmt : str or callable, default: '%g'
(12)                        An unnamed %-style or {}-style format string for the label or a
(12)                        function to call with the value as the first argument.
(12)                        When *fmt* is a string and can be interpreted in both formats,
(12)                        %-style takes precedence over {}-style.
(12)                        .. versionadded:: 3.7
(15)                           Support for {}-style format string and callables.
(8)                     label_type : {'edge', 'center'}, default: 'edge'
(12)                        The label type. Possible values:
(12)                        - 'edge': label placed at the end-point of the bar segment, and
the
(14)                          value displayed will be the position of that end-point.
(12)                        - 'center': label placed in the center of the bar segment, and the
(14)                          value displayed will be the length of that segment.
(14)                          (useful for stacked bars, i.e.,
(14)                          :doc:`/gallery/lines_bars_and_markers/bar_label_demo`)
(8)                     padding : float, default: 0
(12)                        Distance of label from the end of the bar, in points.
(8)                     **kwargs
(12)                        Any remaining keyword arguments are passed through to
(12)                        `.Axes.annotate`. The alignment parameters (
(12)                        *horizontalalignment* / *ha*, *verticalalignment* / *va*) are
(12)                        not supported because the labels are automatically aligned to
(12)                        the bars.
(8)                     Returns
(8)                     -------
(8)                     list of `.Annotation`
(12)                        A list of `.Annotation` instances for the labels.
(8)                     """

2294: (8)                    """
2295: (8)                    Create a stem plot.
2296: (8)                    A stem plot draws lines perpendicular to a baseline at each location
2297: (8)                    *locs* from the baseline to *heads*, and places a marker there. For
2298: (8)                    vertical stem plots (the default), the *locs* are *x* positions, and
2299: (8)                    the *heads* are *y* values. For horizontal stem plots, the *locs* are
2300: (8)                    *y* positions, and the *heads* are *x* values.
2301: (8)                    Call signature::
2302: (10)                     stem([locs,] heads, linefmt=None, markerfmt=None, basefmt=None)
2303: (8)                    The *locs*-positions are optional. *linefmt* may be provided as
2304: (8)                    positional, but all other formats must be provided as keyword
2305: (8)                    arguments.
2306: (8)                    Parameters
2307: (8)                    ----------
2308: (8)                    locs : array-like, default: (0, 1, ..., len(heads) - 1)
2309: (12)                       For vertical stem plots, the x-positions of the stems.
```

```
            For horizontal stem plots, the y-positions of the stems.
        heads : array-like
            For vertical stem plots, the y-values of the stem heads.
            For horizontal stem plots, the x-values of the stem heads.
        linefmt : str, optional
            A string defining the color and/or linestyle of the vertical lines:

            =========  =============
            Character  Line Style
            =========  =============
            ``'-'``    solid line
            ``'--'``   dashed line
            ``'-.'``   dash-dot line
            ``':'``    dotted line
            =========  =============
            Default: 'C0-', i.e. solid line with the first color of the color
            cycle.
            Note: Markers specified through this parameter (e.g. 'x') will be
            silently ignored. Instead, markers should be specified using
            *markerfmt*.
        markerfmt : str, optional
            A string defining the color and/or shape of the markers at the stem

            heads. If the marker is not given, use the marker 'o', i.e. filled
            circles. If the color is not given, use the color from *linefmt*.
        basefmt : str, default: 'C3-' ('C2-' in classic mode)
            A format string defining the properties of the baseline.
        orientation : {'vertical', 'horizontal'}, default: 'vertical'
            The orientation of the stems.
        bottom : float, default: 0
            The y/x-position of the baseline (depending on *orientation*).
        label : str, optional
            The label to use for the stems in legends.
        data : indexable object, optional
            DATA_PARAMETER_PLACEHOLDER
        Returns
        -------
        `.StemContainer`
            The container may be treated like a tuple
            (*markerline*, *stemlines*, *baseline*)

(8)                 """
(8)                 Plot a pie chart.
(8)                 Make a pie chart of array *x*.  The fractional area of each wedge is
(8)                 given by ``x/sum(x)``.
(8)                 The wedges are plotted counterclockwise, by default starting from the
(8)                 x-axis.
(8)                 Parameters
(8)                 ----------
(8)                 x : 1D array-like
(12)                    The wedge sizes.
(8)                 explode : array-like, default: None
(12)                    If not *None*, is a ``len(x)`` array which specifies the fraction
(12)                    of the radius with which to offset each wedge.
(8)                 labels : list, default: None
(12)                    A sequence of strings providing the labels for each wedge
(8)                 colors : :mpltype:`color` or list of :mpltype:`color`, default: None
(12)                    A sequence of colors through which the pie chart will cycle.  If
(12)                    *None*, will use the colors in the currently active cycle.
(8)                 hatch : str or list, default: None
(12)                    Hatching pattern applied to all pie wedges or sequence of patterns
(12)                    through which the chart will cycle. For a list of valid patterns,
(12)                    see :doc:`/gallery/shapes_and_collections/hatch_style_reference`.
(12)                    .. versionadded:: 3.7
```

```
autopct : None or str or callable, default: None
    If not *None*, *autopct* is a string or function used to label the
    wedges with their numeric value. The label will be placed inside
    the wedge. If *autopct* is a format string, the label will be
    ``fmt % pct``. If *autopct* is a function, then it will be called.
pctdistance : float, default: 0.6
    The relative distance along the radius at which the text
    generated by *autopct* is drawn. To draw the text outside the pie,
    set *pctdistance* > 1. This parameter is ignored if *autopct* is
    ``None``.
labeldistance : float or None, default: 1.1
    The relative distance along the radius at which the labels are
    drawn. To draw the labels inside the pie, set  *labeldistance* < 1.

    If set to ``None``, labels are not drawn but are still stored for
    use in `.legend`.
shadow : bool or dict, default: False
    If bool, whether to draw a shadow beneath the pie. If dict, draw a shadow

    passing the properties in the dict to `.Shadow`.
    .. versionadded:: 3.8
        *shadow* can be a dict.
startangle : float, default: 0 degrees
    The angle by which the start of the pie is rotated,
    counterclockwise from the x-axis.
radius : float, default: 1
    The radius of the pie.
counterclock : bool, default: True
    Specify fractions direction, clockwise or counterclockwise.
wedgeprops : dict, default: None
    Dict of arguments passed to each `.patches.Wedge` of the pie.
    For example, ``wedgeprops = {'linewidth': 3}`` sets the width of
    the wedge border lines equal to 3. By default, ``clip_on=False``.
    When there is a conflict between these properties and other
    keywords, properties passed to *wedgeprops* take precedence.
textprops : dict, default: None
    Dict of arguments to pass to the text objects.
center : (float, float), default: (0, 0)
    The coordinates of the center of the chart.
frame : bool, default: False
    Plot Axes frame with the chart if true.
rotatelabels : bool, default: False
    Rotate each label to the angle of the corresponding slice if true.
normalize : bool, default: True
    When *True*, always make a full pie by normalizing x so that
    ``sum(x) == 1``. *False* makes a partial pie if ``sum(x) <= 1``
    and raises a `ValueError` for ``sum(x) > 1``.
data : indexable object, optional
    DATA_PARAMETER_PLACEHOLDER
Returns
-------
patches : list
    A sequence of `matplotlib.patches.Wedge` instances
texts : list
    A list of the label `.Text` instances.
autotexts : list
    A list of `.Text` instances for the numeric labels. This will only
    be returned if the parameter *autopct* is not *None*.
Notes
-----
The pie chart will probably look best if the figure and Axes are
square, or the Axes aspect is equal.
This method sets the aspect ratio of the axis to "equal".
The Axes aspect ratio can be controlled with `.Axes.set_aspect`.

 2653: (8)                  sizes. By default, this draws the data markers/lines as well as the
 2654: (8)                  errorbars. Use fmt='none' to draw errorbars without any data markers.
 2655: (8)                  .. versionadded:: 3.7
 2656: (11)                    Caps and error lines are drawn in polar coordinates on polar plots.
 2657: (8)                  Parameters
 2658: (8)                  ----------
 2659: (8)                  x, y : float or array-like
 2660: (12)                     The data positions.
 2661: (8)                  xerr, yerr : float or array-like, shape(N,) or shape(2, N), optional
 2662: (12)                     The errorbar sizes:
 2663: (12)                     - scalar: Symmetric +/- values for all data points.
 2664: (12)                     - shape(N,): Symmetric +/-values for each data point.
 2665: (12)                     - shape(2, N): Separate - and + values for each bar. First row
 2666: (14)                       contains the lower errors, the second row contains the upper
 2667: (14)                       errors.
 2668: (12)                     - *None*: No errorbar.
 2669: (12)                     All values must be >= 0.
 2670: (12)                     See :doc:`/gallery/statistics/errorbar_features`
 2671: (12)                     for an example on the usage of ``xerr`` and ``yerr``.
 2672: (8)                  fmt : str, default: ''
 2673: (12)                     The format for the data points / data lines. See `.plot` for
 2674: (12)                     details.
 2675: (12)                     Use 'none' (case-insensitive) to plot errorbars without any data
 2676: (12)                     markers.
 2677: (8)                  ecolor : :mpltype:`color`, default: None
 2678: (12)                     The color of the errorbar lines.  If None, use the color of the
 2679: (12)                     line connecting the markers.
 2680: (8)                  elinewidth : float, default: None
 2681: (12)                     The linewidth of the errorbar lines. If None, the linewidth of
 2682: (12)                     the current style is used.
 2683: (8)                  capsize : float, default: :rc:`errorbar.capsize`
 2684: (12)                     The length of the error bar caps in points.
 2685: (8)                  capthick : float, default: None
 2686: (12)                     An alias to the keyword argument *markeredgewidth* (a.k.a. *mew*).
 2687: (12)                     This setting is a more sensible name for the property that
 2688: (12)                     controls the thickness of the error bar cap in points. For
 2689: (12)                     backwards compatibility, if *mew* or *markeredgewidth* are given,
 2690: (12)                     then they will over-ride *capthick*. This may change in future
 2691: (12)                     releases.
 2692: (8)                  barsabove : bool, default: False
 2693: (12)                     If True, will plot the errorbars above the plot
 2694: (12)                     symbols. Default is below.
 2695: (8)                  lolims, uplims, xlolims, xuplims : bool or array-like, default: False
 2696: (12)                     These arguments can be used to indicate that a value gives only
 2697: (12)                     upper/lower limits.  In that case a caret symbol is used to
 2698: (12)                     indicate this. *lims*-arguments may be scalars, or array-likes of
 2699: (12)                     the same length as *xerr* and *yerr*.  To use limits with inverted
 2700: (12)                     axes, `~.Axes.set_xlim` or `~.Axes.set_ylim` must be called before
 2701: (12)                     :meth:`errorbar`.  Note the tricky parameter names: setting e.g.
 2702: (12)                     *lolims* to True means that the y-value is a *lower* limit of the
 2703: (12)                     True value, so, only an *upward*-pointing arrow will be drawn!
 2704: (8)                  errorevery : int or (int, int), default: 1
 2705: (12)                     draws error bars on a subset of the data. *errorevery* =N draws
 2706: (12)                     error bars on the points (x[::N], y[::N]).
 2707: (12)                     *errorevery* =(start, N) draws error bars on the points
 2708: (12)                     (x[start::N], y[start::N]). e.g. errorevery=(6, 3)
 2709: (12)                     adds error bars to the data at (x[6], x[9], x[12], x[15], ...).
 2710: (12)                     Used to avoid overlapping error bars when two series share x-axis
 2711: (12)                     values.
 2712: (8)                  Returns
 2713: (8)                  -------
 2714: (8)                  `.ErrorbarContainer`
```

```
(12)                        The container contains:
(12)                        - data_line : A `~matplotlib.lines.Line2D` instance of x, y plot
markers
(14)                          and/or line.
(12)                        - caplines : A tuple of `~matplotlib.lines.Line2D` instances of
the error
(14)                          bar caps.
(12)                        - barlinecols : A tuple of `.LineCollection` with the horizontal
and
(14)                          vertical error ranges.
(8)                     Other Parameters
(8)                     ----------------
(8)                     data : indexable object, optional
(12)                        DATA_PARAMETER_PLACEHOLDER
(8)                     **kwargs
(12)                        All other keyword arguments are passed on to the `~.Axes.plot`
call
(12)                        drawing the markers. For example, this code makes big red squares
(12)                        with thick green edges::
(16)                            x, y, yerr = rand(3, 10)
(16)                            errorbar(x, y, yerr, marker='s', mfc='red',
(25)                                     mec='green', ms=20, mew=4)
(12)                        where *mfc*, *mec*, *ms* and *mew* are aliases for the longer
(12)                        property names, *markerfacecolor*, *markeredgecolor*, *markersize*
(12)                        and *markeredgewidth*.
(12)                        Valid kwargs for the marker properties are:
(12)                        - *dashes*
(12)                        - *dash_capstyle*
(12)                        - *dash_joinstyle*
(12)                        - *drawstyle*
(12)                        - *fillstyle*
(12)                        - *linestyle*
(12)                        - *marker*
(12)                        - *markeredgecolor*
(12)                        - *markeredgewidth*
(12)                        - *markerfacecolor*
(12)                        - *markerfacecoloralt*
(12)                        - *markersize*
(12)                        - *markevery*
(12)                        - *solid_capstyle*
(12)                        - *solid_joinstyle*
(12)                        Refer to the corresponding `.Line2D` property for more details:
(12)                        %(Line2D:kwdoc)s
(8)                     """

(31)                                       |-----:-----|
(15)                       o      |--------|     :     |--------|    o  o
(31)                                       |-----:-----|
(13)                     flier             <----------->            fliers
(36)                                            IQR
(8)                 Parameters
(8)                 ----------
(8)                 x : Array or a sequence of vectors.
(12)                    The input data.  If a 2D array, a boxplot is drawn for each column
(12)                    in *x*.  If a sequence of 1D arrays, a boxplot is drawn for each
(12)                    array in *x*.
(8)                 notch : bool, default: :rc:`boxplot.notch`
(12)                    Whether to draw a notched boxplot (`True`), or a rectangular
(12)                    boxplot (`False`).  The notches represent the confidence interval
(12)                    (CI) around the median.  The documentation for *bootstrap*
(12)                    describes how the locations of the notches are computed by
(12)                    default, but their locations may also be overridden by setting the
(12)                    *conf_intervals* parameter.
(12)                    .. note::
(16)                        In cases where the values of the CI are less than the
(16)                        lower quartile or greater than the upper quartile, the
(16)                        notches will extend beyond the box, giving it a
(16)                        distinctive "flipped" appearance. This is expected
(16)                        behavior and consistent with other statistical
(16)                        visualization packages.
(8)                 sym : str, optional
(12)                    The default symbol for flier points.  An empty string ('') hides
(12)                    the fliers.  If `None`, then the fliers default to 'b+'.  More
(12)                    control is provided by the *flierprops* parameter.
(8)                 vert : bool, default: :rc:`boxplot.vertical`
(12)                    If `True`, draws vertical boxes.
(12)                    If `False`, draw horizontal boxes.
(8)                 whis : float or (float, float), default: 1.5
(12)                    The position of the whiskers.
(12)                    If a float, the lower whisker is at the lowest datum above
(12)                    ``Q1 - whis*(Q3-Q1)``, and the upper whisker at the highest datum
(12)                    below ``Q3 + whis*(Q3-Q1)``, where Q1 and Q3 are the first and
(12)                    third quartiles.  The default value of ``whis = 1.5`` corresponds
(12)                    to Tukey's original definition of boxplots.
(12)                    If a pair of floats, they indicate the percentiles at which to
```

```
(12)                        draw the whiskers (e.g., (5, 95)).  In particular, setting this to
(12)                        (0, 100) results in whiskers covering the whole range of the data.
(12)                        In the edge case where ``Q1 == Q3``, *whis* is automatically set
(12)                        to (0, 100) (cover the whole range of the data) if *autorange* is
(12)                        True.
(12)                        Beyond the whiskers, data are considered outliers and are plotted
(12)                        as individual points.
(8)                     bootstrap : int, optional
(12)                        Specifies whether to bootstrap the confidence intervals
(12)                        around the median for notched boxplots. If *bootstrap* is
(12)                        None, no bootstrapping is performed, and notches are
(12)                        calculated using a Gaussian-based asymptotic approximation
(12)                        (see McGill, R., Tukey, J.W., and Larsen, W.A., 1978, and
(12)                        Kendall and Stuart, 1967). Otherwise, bootstrap specifies
(12)                        the number of times to bootstrap the median to determine its
(12)                        95% confidence intervals. Values between 1000 and 10000 are
(12)                        recommended.
(8)                     usermedians : 1D array-like, optional
(12)                        A 1D array-like of length ``len(x)``.  Each entry that is not
(12)                        `None` forces the value of the median for the corresponding
(12)                        dataset.  For entries that are `None`, the medians are computed
(12)                        by Matplotlib as normal.
(8)                     conf_intervals : array-like, optional
(12)                        A 2D array-like of shape ``(len(x), 2)``.  Each entry that is not
(12)                        None forces the location of the corresponding notch (which is
(12)                        only drawn if *notch* is `True`).  For entries that are `None`,
(12)                        the notches are computed by the method specified by the other
(12)                        parameters (e.g., *bootstrap*).
(8)                     positions : array-like, optional
(12)                        The positions of the boxes. The ticks and limits are
(12)                        automatically set to match the positions. Defaults to
(12)                        ``range(1, N+1)`` where N is the number of boxes to be drawn.
(8)                     widths : float or array-like
(12)                        The widths of the boxes.  The default is 0.5, or ``0.15*(distance
(12)                        between extreme positions)``, if that is smaller.
(8)                     patch_artist : bool, default: :rc:`boxplot.patchartist`
(12)                        If `False` produces boxes with the Line2D artist. Otherwise,
(12)                        boxes are drawn with Patch artists.
(8)                     tick_labels : list of str, optional
(12)                        The tick labels of each boxplot.
(12)                        Ticks are always placed at the box *positions*. If *tick_labels*
is given,
(12)                        the ticks are labelled accordingly. Otherwise, they keep their
numeric
(12)                        values.
(12)                        .. versionchanged:: 3.9
(16)                            Renamed from *labels*, which is deprecated since 3.9
(16)                            and will be removed in 3.11.
(8)                     manage_ticks : bool, default: True
(12)                        If True, the tick locations and labels will be adjusted to match
(12)                        the boxplot positions.
(8)                     autorange : bool, default: False
(12)                        When `True` and the data are distributed such that the 25th and
(12)                        75th percentiles are equal, *whis* is set to (0, 100) such
(12)                        that the whisker ends are at the minimum and maximum of the data.
(8)                     meanline : bool, default: :rc:`boxplot.meanline`
(12)                        If `True` (and *showmeans* is `True`), will try to render the
(12)                        mean as a line spanning the full width of the box according to
(12)                        *meanprops* (see below).  Not recommended if *shownotches* is also
(12)                        True.  Otherwise, means will be shown as points.
(8)                     zorder : float, default: ``Line2D.zorder = 2``
(12)                        The zorder of the boxplot.
(8)                     Returns
(8)                     -------
(8)                     dict
(10)                      A dictionary mapping each component of the boxplot to a list
(10)                      of the `.Line2D` instances created. That dictionary has the
(10)                      following keys (assuming vertical boxplots):
(10)                      - ``boxes``: the main body of the boxplot showing the
```

```
3050: (12)                      quartiles and the median's confidence intervals if
3051: (12)                      enabled.
3052: (10)                    - ``medians``: horizontal lines at the median of each box.
3053: (10)                    - ``whiskers``: the vertical lines extending to the most
3054: (12)                      extreme, non-outlier data points.
3055: (10)                    - ``caps``: the horizontal lines at the ends of the
3056: (12)                      whiskers.
3057: (10)                    - ``fliers``: points representing data that extend beyond
3058: (12)                      the whiskers (fliers).
3059: (10)                    - ``means``: points or lines representing the means.
3060: (8)                   Other Parameters
3061: (8)                   ----------------
3062: (8)                   showcaps : bool, default: :rc:`boxplot.showcaps`
3063: (12)                      Show the caps on the ends of whiskers.
3064: (8)                   showbox : bool, default: :rc:`boxplot.showbox`
3065: (12)                      Show the central box.
3066: (8)                   showfliers : bool, default: :rc:`boxplot.showfliers`
3067: (12)                      Show the outliers beyond the caps.
3068: (8)                   showmeans : bool, default: :rc:`boxplot.showmeans`
3069: (12)                      Show the arithmetic means.
3070: (8)                   capprops : dict, default: None
3071: (12)                      The style of the caps.
3072: (8)                   capwidths : float or array, default: None
3073: (12)                      The widths of the caps.
3074: (8)                   boxprops : dict, default: None
3075: (12)                      The style of the box.
3076: (8)                   whiskerprops : dict, default: None
3077: (12)                      The style of the whiskers.
3078: (8)                   flierprops : dict, default: None
3079: (12)                      The style of the fliers.
3080: (8)                   medianprops : dict, default: None
3081: (12)                      The style of the median.
3082: (8)                   meanprops : dict, default: None
3083: (12)                      The style of the mean.
3084: (8)                   label : str or list of str, optional
3085: (12)                      Legend labels. Use a single string when all boxes have the same
style and
3086: (12)                      you only want a single legend entry for them. Use a list of
strings to
3087: (12)                      label all boxes individually. To be distinguishable, the boxes
should be
3088: (12)                      styled individually, which is currently only possible by modifying
the
3089: (12)                      returned artists, see e.g.
:doc:`/gallery/statistics/boxplot_demo`.
3090: (12)                      In the case of a single string, the legend entry will technically
be
3091: (12)                      associated with the first box only. By default, the legend will
show the
3092: (12)                      median line (``result["medians"]``); if *patch_artist* is True,
the legend
3093: (12)                      will show the box `.Patch` artists (``result["boxes"]``) instead.
3094: (12)                      .. versionadded:: 3.9
3095: (8)                   data : indexable object, optional
3096: (12)                      DATA_PARAMETER_PLACEHOLDER
3097: (8)                   See Also

                         flier                                     fliers
                    .. note::
                        This is a low-level drawing function for when you already
                        have the statistical parameters. If you want a boxplot based
                        on a dataset, use `~.Axes.boxplot` instead.
                    Parameters
                    ----------
                    bxpstats : list of dicts
                      A list of dictionaries containing stats for each boxplot.
                      Required keys are:
                      - ``med``: Median (scalar).
                      - ``q1``, ``q3``: First & third quartiles (scalars).
                      - ``whislo``, ``whishi``: Lower & upper whisker positions (scalars).
                      Optional keys are:
                      - ``mean``: Mean (scalar).  Needed if ``showmeans=True``.
                      - ``fliers``: Data beyond the whiskers (array-like).
                        Needed if ``showfliers=True``.
                      - ``cilo``, ``cihi``: Lower & upper confidence intervals
                        about the median. Needed if ``shownotches=True``.
                      - ``label``: Name of the dataset (str).  If available,
                        this will be used a tick label for the boxplot
                    positions : array-like, default: [1, 2, ..., n]
                      The positions of the boxes. The ticks and limits
                      are automatically set to match the positions.
                    widths : float or array-like, default: None
                      The widths of the boxes.  The default is
                      ``clip(0.15*(distance between extreme positions), 0.15, 0.5)``.
                    capwidths : float or array-like, default: None
                      Either a scalar or a vector and sets the width of each cap.
                      The default is ``0.5*(width of the box)``, see *widths*.
                    vert : bool, default: True
                      If `True` (default), makes the boxes vertical.
                      If `False`, makes horizontal boxes.
                    patch_artist : bool, default: False
                      If `False` produces boxes with the `.Line2D` artist.
                      If `True` produces boxes with the `~matplotlib.patches.Patch`
artist.
                    shownotches, showmeans, showcaps, showbox, showfliers : bool
                      Whether to draw the CI notches, the mean value (both default to
                      False), the caps, the box, and the fliers (all three default to
                      True).
                    boxprops, whiskerprops, capprops, flierprops, medianprops, meanprops
```

```
:\
(1)            dict, optional
(10)                     Artist properties for the boxes, whiskers, caps, fliers, medians,
and
(10)                     means.

(10)                     If `True` (and *showmeans* is `True`), will try to render the mean
(10)                     as a line spanning the full width of the box according to
(10)                     *meanprops*. Not recommended if *shownotches* is also True.
(10)                     Otherwise, means will be shown as points.
(8)                    manage_ticks : bool, default: True
(10)                     If True, the tick locations and labels will be adjusted to match the
(10)                     boxplot positions.
(8)                    label : str or list of str, optional
(12)                         Legend labels. Use a single string when all boxes have the same
style and
(12)                         you only want a single legend entry for them. Use a list of
strings to
(12)                         label all boxes individually. To be distinguishable, the boxes
should be
(12)                         styled individually, which is currently only possible by modifying
the
(12)                         returned artists, see e.g.
:doc:`/gallery/statistics/boxplot_demo`.
(12)                         In the case of a single string, the legend entry will technically
be
(12)                         associated with the first box only. By default, the legend will
show the
(12)                         median line (``result["medians"]``); if *patch_artist* is True,
the legend
(12)                         will show the box `.Patch` artists (``result["boxes"]``) instead.
(12)                         .. versionadded:: 3.9
(8)                    zorder : float, default: ``Line2D.zorder = 2``
(10)                     The zorder of the resulting boxplot.
(8)                    Returns
(8)                    -------
(8)                    dict
(10)                     A dictionary mapping each component of the boxplot to a list
(10)                     of the `.Line2D` instances created. That dictionary has the
(10)                     following keys (assuming vertical boxplots):
(10)                     - ``boxes``: main bodies of the boxplot showing the quartiles, and
(12)                       the median's confidence intervals if enabled.
(10)                     - ``medians``: horizontal lines at the median of each box.
(10)                     - ``whiskers``: vertical lines up to the last non-outlier data.
(10)                     - ``caps``: horizontal lines at the ends of the whiskers.
(10)                     - ``fliers``: points representing data beyond the whiskers (fliers).
(10)                     - ``means``: points or lines representing the means.

3587: (8)                   """
3588: (8)                   A scatter plot of *y* vs. *x* with varying marker size and/or color.
3589: (8)                   Parameters
3590: (8)                   ----------
3591: (8)                   x, y : float or array-like, shape (n, )
3592: (12)                      The data positions.
3593: (8)                   s : float or array-like, shape (n, ), optional
3594: (12)                      The marker size in points**2 (typographic points are 1/72 in.).
3595: (12)                      Default is ``rcParams['lines.markersize'] ** 2``.
3596: (12)                      The linewidth and edgecolor can visually interact with the marker
3597: (12)                      size, and can lead to artifacts if the marker size is smaller than
3598: (12)                      the linewidth.
3599: (12)                      If the linewidth is greater than 0 and the edgecolor is anything
3600: (12)                      but *'none'*, then the effective size of the marker will be
3601: (12)                      increased by half the linewidth because the stroke will be
centered
3602: (12)                      on the edge of the shape.
3603: (12)                      To eliminate the marker edge either set *linewidth=0* or
3604: (12)                      *edgecolor='none'*.
3605: (8)                   c : array-like or list of :mpltype:`color` or :mpltype:`color`,
optional
3606: (12)                      The marker colors. Possible values:
3607: (12)                      - A scalar or sequence of n numbers to be mapped to colors using
3608: (14)                        *cmap* and *norm*.
3609: (12)                      - A 2D array in which the rows are RGB or RGBA.
3610: (12)                      - A sequence of colors of length n.
3611: (12)                      - A single color format string.
3612: (12)                      Note that *c* should not be a single numeric RGB or RGBA sequence
3613: (12)                      because that is indistinguishable from an array of values to be
3614: (12)                      colormapped. If you want to specify the same RGB or RGBA value for
3615: (12)                      all points, use a 2D array with a single row.  Otherwise,
3616: (12)                      value-matching will have precedence in case of a size matching
with
3617: (12)                      *x* and *y*.
3618: (12)                      If you wish to specify a single color for all points
3619: (12)                      prefer the *color* keyword argument.
3620: (12)                      Defaults to `None`. In that case the marker color is determined
3621: (12)                      by the value of *color*, *facecolor* or *facecolors*. In case
3622: (12)                      those are not specified or `None`, the marker color is determined
3623: (12)                      by the next color of the ``Axes``' current "shape and fill" color
3624: (12)                      cycle. This cycle defaults to :rc:`axes.prop_cycle`.
3625: (8)                   marker : `~.markers.MarkerStyle`, default: :rc:`scatter.marker`
3626: (12)                      The marker style. *marker* can be either an instance of the class
3627: (12)                      or the text shorthand for a particular marker.
3628: (12)                      See :mod:`matplotlib.markers` for more information about marker
3629: (12)                      styles.
3630: (8)                   %(cmap_doc)s
3631: (12)                      This parameter is ignored if *c* is RGB(A).
3632: (8)                   %(norm_doc)s
3633: (12)                      This parameter is ignored if *c* is RGB(A).
3634: (8)                   %(vmin_vmax_doc)s
3635: (12)                      This parameter is ignored if *c* is RGB(A).
3636: (8)                   alpha : float, default: None
3637: (12)                      The alpha blending value, between 0 (transparent) and 1 (opaque).

3639: (12)                      The linewidth of the marker edges. Note: The default *edgecolors*
3640: (12)                      is 'face'. You may want to change this as well.
3641: (8)                   edgecolors : {'face', 'none', *None*} or :mpltype:`color` or list of \
3642: (0)            :mpltype:`color`, default: :rc:`scatter.edgecolors`
```

```
(12)                        The edge color of the marker. Possible values:
(12)                        - 'face': The edge color will always be the same as the face
color.
(12)                        - 'none': No patch boundary will be drawn.
(12)                        - A color or sequence of colors.
(12)                        For non-filled markers, *edgecolors* is ignored. Instead, the
color
(12)                        is determined like with 'face', i.e. from *c*, *colors*, or
(12)                        *facecolors*.
(8)                     plotnonfinite : bool, default: False
(12)                        Whether to plot points with nonfinite *c* (i.e. ``inf``, ``-inf``
(12)                        or ``nan``). If ``True`` the points are drawn with the *bad*
(12)                        colormap color (see `.Colormap.set_bad`).
(8)                     Returns
(8)                     -------
(8)                     `~matplotlib.collections.PathCollection`
(8)                     Other Parameters
(8)                     ----------------
(8)                     data : indexable object, optional
(12)                        DATA_PARAMETER_PLACEHOLDER
(8)                     **kwargs : `~matplotlib.collections.Collection` properties
(8)                     See Also
(8)                     --------
(8)                     plot : To plot scatter plots when markers are identical in size and
(12)                        color.
(8)                     Notes
(8)                     -----
(8)                     * The `.plot` function will be faster for scatterplots where markers
(10)                      don't vary in size or color.
(8)                     * Any or all of *x*, *y*, *s*, and *c* may be masked arrays, in which
(10)                      case all masks will be combined and only unmasked points will be
(10)                      plotted.
(8)                     * Fundamentally, scatter works with 1D arrays; *x*, *y*, *s*, and *c*
(10)                      may be input as N-D arrays, but within scatter they will be
(10)                      flattened. The exception is *c*, which will be flattened only if its
(10)                      size matches the size of *x* and *y*.

(8)                 """
(8)                 Make a 2D hexagonal binning plot of points *x*, *y*.
(8)                 If *C* is *None*, the value of the hexagon is determined by the number
(8)                 of points in the hexagon. Otherwise, *C* specifies values at the
(8)                 coordinate (x[i], y[i]). For each hexagon, these values are reduced
(8)                 using *reduce_C_function*.
(8)                 Parameters
(8)                 ----------
(8)                 x, y : array-like
(12)                    The data positions. *x* and *y* must be of the same length.
(8)                 C : array-like, optional
(12)                    If given, these values are accumulated in the bins. Otherwise,
(12)                    every point has a value of 1. Must be of the same length as *x*
(12)                    and *y*.
(8)                 gridsize : int or (int, int), default: 100
(12)                    If a single int, the number of hexagons in the *x*-direction.
(12)                    The number of hexagons in the *y*-direction is chosen such that
(12)                    the hexagons are approximately regular.
(12)                    Alternatively, if a tuple (*nx*, *ny*), the number of hexagons
(12)                    in the *x*-direction and the *y*-direction. In the
(12)                    *y*-direction, counting is done along vertically aligned
(12)                    hexagons, not along the zig-zag chains of hexagons; see the
(12)                    following illustration.
(12)                    .. plot::
(15)                       import numpy
(15)                       import matplotlib.pyplot as plt
(15)                       np.random.seed(19680801)
(15)                       n= 300
(15)                       x = np.random.standard_normal(n)
(15)                       y = np.random.standard_normal(n)
(15)                       fig, ax = plt.subplots(figsize=(4, 4))
(15)                       h = ax.hexbin(x, y, gridsize=(5, 3))
(15)                       hx, hy = h.get_offsets().T
(15)                       ax.plot(hx[24::3], hy[24::3], 'ro-')
(15)                       ax.plot(hx[-3:], hy[-3:], 'ro-')
(15)                       ax.set_title('gridsize=(5, 3)')
(15)                       ax.axis('off')
(12)                    To get approximately regular hexagons, choose
(12)                    :math:`n_x = \\sqrt{3}\\,n_y`.
(8)                 bins : 'log' or int or sequence, default: None
(12)                    Discretization of the hexagon values.
(12)                    - If *None*, no binning is applied; the color of each hexagon
(14)                      directly corresponds to its count value.
(12)                    - If 'log', use a logarithmic scale for the colormap.
(14)                      Internally, :math:`log_{10}(i+1)` is used to determine the
(14)                      hexagon color. This is equivalent to ``norm=LogNorm()``.
(12)                    - If an integer, divide the counts in the specified number
(14)                      of bins, and color the hexagons accordingly.
(12)                    - If a sequence of values, the values of the lower bound of
(14)                      the bins to be used.
(8)                 xscale : {'linear', 'log'}, default: 'linear'
(12)                    Use a linear or log10 scale on the horizontal axis.
(8)                 yscale : {'linear', 'log'}, default: 'linear'
(12)                    Use a linear or log10 scale on the vertical axis.
(8)                 mincnt : int >= 0, default: *None*
(12)                    If not *None*, only display cells with at least *mincnt*

(8)                 marginals : bool, default: *False*
```

```
3848: (12)                      If marginals is *True*, plot the marginal density as
3849: (12)                      colormapped rectangles along the bottom of the x-axis and
3850: (12)                      left of the y-axis.
3851: (8)                   extent : 4-tuple of float, default: *None*
3852: (12)                      The limits of the bins (xmin, xmax, ymin, ymax).
3853: (12)                      The default assigns the limits based on
3854: (12)                      *gridsize*, *x*, *y*, *xscale* and *yscale*.
3855: (12)                      If *xscale* or *yscale* is set to 'log', the limits are
3856: (12)                      expected to be the exponent for a power of 10. E.g. for
3857: (12)                      x-limits of 1 and 50 in 'linear' scale and y-limits
3858: (12)                      of 10 and 1000 in 'log' scale, enter (1, 50, 1, 3).
3859: (8)                   Returns
3860: (8)                   -------
3861: (8)                   `~matplotlib.collections.PolyCollection`
3862: (12)                      A `.PolyCollection` defining the hexagonal bins.
3863: (12)                      - `.PolyCollection.get_offsets` contains a Mx2 array containing
3864: (14)                        the x, y positions of the M hexagon centers.
3865: (12)                      - `.PolyCollection.get_array` contains the values of the M
3866: (14)                        hexagons.
3867: (12)                      If *marginals* is *True*, horizontal
3868: (12)                      bar and vertical bar (both PolyCollections) will be attached
3869: (12)                      to the return collection as attributes *hbar* and *vbar*.
3870: (8)                   Other Parameters
3871: (8)                   ----------------
3872: (8)                   %(cmap_doc)s
3873: (8)                   %(norm_doc)s
3874: (8)                   %(vmin_vmax_doc)s
3875: (8)                   alpha : float between 0 and 1, optional
3876: (12)                      The alpha blending value, between 0 (transparent) and 1 (opaque).
3877: (8)                   linewidths : float, default: *None*
3878: (12)                      If *None*, defaults to :rc:`patch.linewidth`.
3879: (8)                   edgecolors : {'face', 'none', *None*} or color, default: 'face'
3880: (12)                      The color of the hexagon edges. Possible values are:
3881: (12)                      - 'face': Draw the edges in the same color as the fill color.
3882: (12)                      - 'none': No edges are drawn. This can sometimes lead to unsightly
3883: (14)                        unpainted pixels between the hexagons.
3884: (12)                      - *None*: Draw outlines in the default color.
3885: (12)                      - An explicit color.
3886: (8)                   reduce_C_function : callable, default: `numpy.mean`
3887: (12)                      The function to aggregate *C* within the bins. It is ignored if
3888: (12)                      *C* is not given. This must have the signature::
3889: (16)                          def reduce_C_function(C: array) -> float
3890: (12)                      Commonly used functions are:
3891: (12)                      - `numpy.mean`: average of the points
3892: (12)                      - `numpy.sum`: integral of the point values
3893: (12)                      - `numpy.amax`: value taken from the largest point
3894: (12)                      By default will only reduce cells with at least 1 point because
some
3895: (12)                      reduction functions (such as `numpy.amax`) will error/warn with
empty
3896: (12)                      input. Changing *mincnt* will adjust the cutoff, and if set to 0
will
3897: (12)                      pass empty input to the reduction function.
3898: (8)                   data : indexable object, optional
3899: (12)                      DATA_PARAMETER_PLACEHOLDER
3900: (8)                   **kwargs : `~matplotlib.collections.PolyCollection` properties
3901: (12)                      All other keyword arguments are passed on to `.PolyCollection`:

(8)                 Plot filled polygons.
(8)                 Parameters
(8)                 ----------
(8)                 *args : sequence of x, y, [color]
(12)                    Each polygon is defined by the lists of *x* and *y* positions of
(12)                    its nodes, optionally followed by a *color* specifier. See
(12)                    :mod:`matplotlib.colors` for supported color specifiers. The
(12)                    standard color cycle is used for polygons without a color
(12)                    specifier.
(12)                    You can plot multiple polygons by providing multiple *x*, *y*,
(12)                    *[color]* groups.
(12)                    For example, each of the following is legal::
(16)                        ax.fill(x, y)                    # a polygon with default
color
(16)                        ax.fill(x, y, "b")               # a blue polygon
(16)                        ax.fill(x, y, x2, y2)            # two polygons
(16)                        ax.fill(x, y, "b", x2, y2, "r")  # a blue and a red polygon
(8)                 data : indexable object, optional
(12)                    An object with labelled data. If given, provide the label names to
(12)                    plot in *x* and *y*, e.g.::
(16)                        ax.fill("time", "signal",
(24)                                data={"time": [0, 1, 2], "signal": [0, 1, 0]})
(8)                 Returns
(8)                 -------
(8)                 list of `~matplotlib.patches.Polygon`
(8)                 Other Parameters
(8)                 ----------------
(8)                 **kwargs : `~matplotlib.patches.Polygon` properties
(8)                 Notes
(8)                 -----
(8)                 Use :meth:`fill_between` if you would like to fill the region between
(8)                 two curves.
(8)                 """

 4199: (8)                    Fill the area between two {dir} curves.
 4200: (8)                    The curves are defined by the points (*{ind}*, *{dep}1*) and (*{ind}*,
 4201: (8)                    *{dep}2*).  This creates one or multiple polygons describing the
 filled
 4202: (8)                    area.
 4203: (8)                    You may exclude some {dir} sections from filling using *where*.
 4204: (8)                    By default, the edges connect the given points directly.  Use *step*
 4205: (8)                    if the filling should be a step function, i.e. constant in between
 4206: (8)                    *{ind}*.
 4207: (8)                    Parameters
 4208: (8)                    ----------
 4209: (8)                    {ind} : array (length N)
 4210: (12)                       The {ind} coordinates of the nodes defining the curves.
 4211: (8)                    {dep}1 : array (length N) or scalar
 4212: (12)                       The {dep} coordinates of the nodes defining the first curve.
 4213: (8)                    {dep}2 : array (length N) or scalar, default: 0
 4214: (12)                       The {dep} coordinates of the nodes defining the second curve.
 4215: (8)                    where : array of bool (length N), optional
 4216: (12)                       Define *where* to exclude some {dir} regions from being filled.
 4217: (12)                       The filled regions are defined by the coordinates ``{ind}
 [where]``.
 4218: (12)                       More precisely, fill between ``{ind}[i]`` and ``{ind}[i+1]`` if
 4219: (12)                       ``where[i] and where[i+1]``.  Note that this definition implies
 4220: (12)                       that an isolated *True* value between two *False* values in
 *where*
 4221: (12)                       will not result in filling.  Both sides of the *True* position
 4222: (12)                       remain unfilled due to the adjacent *False* values.
 4223: (8)                    interpolate : bool, default: False
 4224: (12)                       This option is only relevant if *where* is used and the two curves
 4225: (12)                       are crossing each other.
 4226: (12)                       Semantically, *where* is often used for *{dep}1* > *{dep}2* or
 4227: (12)                       similar.  By default, the nodes of the polygon defining the filled
 4228: (12)                       region will only be placed at the positions in the *{ind}* array.
 4229: (12)                       Such a polygon cannot describe the above semantics close to the
 4230: (12)                       intersection.  The {ind}-sections containing the intersection are
 4231: (12)                       simply clipped.
 4232: (12)                       Setting *interpolate* to *True* will calculate the actual
 4233: (12)                       intersection point and extend the filled region up to this point.
 4234: (8)                    step : {{'pre', 'post', 'mid'}}, optional
 4235: (12)                       Define *step* if the filling should be a step function,
 4236: (12)                       i.e. constant in between *{ind}*.  The value determines where the
 4237: (12)                       step will occur:
 4238: (12)                       - 'pre': The y value is continued constantly to the left from
 4239: (14)                         every *x* position, i.e. the interval ``(x[i-1], x[i]]`` has the
 4240: (14)                         value ``y[i]``.
 4241: (12)                       - 'post': The y value is continued constantly to the right from
 4242: (14)                         every *x* position, i.e. the interval ``[x[i], x[i+1])`` has the
 4243: (14)                         value ``y[i]``.
 4244: (12)                       - 'mid': Steps occur half-way between the *x* positions.
 4245: (8)                    Returns
 4246: (8)                    -------
 4247: (8)                    `.PolyCollection`

4375: (8)                   """
4376: (8)                   Display data as an image, i.e., on a 2D regular raster.
4377: (8)                   The input may either be actual RGB(A) data, or 2D scalar data, which
4378: (8)                   will be rendered as a pseudocolor image. For displaying a grayscale
4379: (8)                   image, set up the colormapping using the parameters
4380: (8)                   ``cmap='gray', vmin=0, vmax=255``.
4381: (8)                   The number of pixels used to render an image is set by the Axes size
4382: (8)                   and the figure *dpi*. This can lead to aliasing artifacts when
4383: (8)                   the image is resampled, because the displayed image size will usually
4384: (8)                   not match the size of *X* (see
4385: (8)                   :doc:`/gallery/images_contours_and_fields/image_antialiasing`).
4386: (8)                   The resampling can be controlled via the *interpolation* parameter
4387: (8)                   and/or :rc:`image.interpolation`.
4388: (8)                   Parameters
4389: (8)                   ----------
4390: (8)                   X : array-like or PIL image
```

```
(12)                        The image data. Supported array shapes are:
(12)                        - (M, N): an image with scalar data. The values are mapped to
(14)                          colors using normalization and a colormap. See parameters
*norm*,
(14)                          *cmap*, *vmin*, *vmax*.
(12)                        - (M, N, 3): an image with RGB values (0-1 float or 0-255 int).
(12)                        - (M, N, 4): an image with RGBA values (0-1 float or 0-255 int),
(14)                          i.e. including transparency.
(12)                        The first two dimensions (M, N) define the rows and columns of
(12)                        the image.
(12)                        Out-of-range RGB(A) values are clipped.
(8)                     %(cmap_doc)s
(12)                        This parameter is ignored if *X* is RGB(A).
(8)                     %(norm_doc)s
(12)                        This parameter is ignored if *X* is RGB(A).
(8)                     %(vmin_vmax_doc)s
(12)                        This parameter is ignored if *X* is RGB(A).
(8)                     aspect : {'equal', 'auto'} or float or None, default: None
(12)                        The aspect ratio of the Axes.  This parameter is particularly
(12)                        relevant for images since it determines whether data pixels are
(12)                        square.
(12)                        This parameter is a shortcut for explicitly calling
(12)                        `.Axes.set_aspect`. See there for further details.
(12)                        - 'equal': Ensures an aspect ratio of 1. Pixels will be square
(14)                          (unless pixel sizes are explicitly made non-square in data
(14)                          coordinates using *extent*).
(12)                        - 'auto': The Axes is kept fixed and the aspect is adjusted so
(14)                          that the data fit in the Axes. In general, this will result in
(14)                          non-square pixels.
(12)                        Normally, None (the default) means to use :rc:`image.aspect`.
However, if
(12)                        the image uses a transform that does not contain the axes data
transform,
(12)                        then None means to not modify the axes aspect at all (in that
case, directly
(12)                        call `.Axes.set_aspect` if desired).
(8)                     interpolation : str, default: :rc:`image.interpolation`
(12)                        The interpolation method used.
(12)                        Supported values are 'none', 'antialiased', 'nearest', 'bilinear',
(12)                        'bicubic', 'spline16', 'spline36', 'hanning', 'hamming',
'hermite',
(12)                        'kaiser', 'quadric', 'catrom', 'gaussian', 'bessel', 'mitchell',
(12)                        'sinc', 'lanczos', 'blackman'.
(12)                        The data *X* is resampled to the pixel size of the image on the
(12)                        figure canvas, using the interpolation method to either up- or
(12)                        downsample the data.
(12)                        If *interpolation* is 'none', then for the ps, pdf, and svg
(12)                        backends no down- or upsampling occurs, and the image data is
(12)                        passed to the backend as a native image.  Note that different ps,
(12)                        pdf, and svg viewers may display these raw pixels differently. On
(12)                        other backends, 'none' is the same as 'nearest'.
(12)                        If *interpolation* is the default 'antialiased', then 'nearest'
(12)                        interpolation is used if the image is upsampled by more than a
(12)                        factor of three (i.e. the number of display pixels is at least
(12)                        three times the size of the data array).  If the upsampling rate
is
(12)                        smaller than 3, or the image is downsampled, then 'hanning'
(12)                        interpolation is used to act as an anti-aliasing filter, unless
the
(12)                        image happens to be upsampled by exactly a factor of two or one.
(12)                        See
(12)                        :doc:`/gallery/images_contours_and_fields/interpolation_methods`
(12)                        for an overview of the supported interpolation methods, and
(12)                        :doc:`/gallery/images_contours_and_fields/image_antialiasing` for
(12)                        a discussion of image antialiasing.
(12)                        Some interpolation methods require an additional radius parameter,
(12)                        which can be set by *filterrad*. Additionally, the antigrain image
(12)                        resize filter is controlled by the parameter *filternorm*.
(8)                     interpolation_stage : {'data', 'rgba'}, default: 'data'
```

```
(12)                        If 'data', interpolation
(12)                        is carried out on the data provided by the user.  If 'rgba', the
(12)                        interpolation is carried out after the colormapping has been
(12)                        applied (visual interpolation).
(8)                     alpha : float or array-like, optional
(12)                        The alpha blending value, between 0 (transparent) and 1 (opaque).
(12)                        If *alpha* is an array, the alpha blending values are applied
pixel
(12)                        by pixel, and *alpha* must have the same shape as *X*.
(8)                     origin : {'upper', 'lower'}, default: :rc:`image.origin`
(12)                        Place the [0, 0] index of the array in the upper left or lower
(12)                        left corner of the Axes. The convention (the default) 'upper' is
(12)                        typically used for matrices and images.
(12)                        Note that the vertical axis points upward for 'lower'
(12)                        but downward for 'upper'.
(12)                        See the :ref:`imshow_extent` tutorial for
(12)                        examples and a more detailed description.
(8)                     extent : floats (left, right, bottom, top), optional
(12)                        The bounding box in data coordinates that the image will fill.
(12)                        These values may be unitful and match the units of the Axes.
(12)                        The image is stretched individually along x and y to fill the box.
(12)                        The default extent is determined by the following conditions.
(12)                        Pixels have unit size in data coordinates. Their centers are on
(12)                        integer coordinates, and their center coordinates range from 0 to
(12)                        columns-1 horizontally and from 0 to rows-1 vertically.
(12)                        Note that the direction of the vertical axis and thus the default
(12)                        values for top and bottom depend on *origin*:
(12)                        - For ``origin == 'upper'`` the default is
(14)                          ``(-0.5, numcols-0.5, numrows-0.5, -0.5)``.
(12)                        - For ``origin == 'lower'`` the default is
(14)                          ``(-0.5, numcols-0.5, -0.5, numrows-0.5)``.
(12)                        See the :ref:`imshow_extent` tutorial for
(12)                        examples and a more detailed description.
(8)                     filternorm : bool, default: True
(12)                        A parameter for the antigrain image resize filter (see the
(12)                        antigrain documentation).  If *filternorm* is set, the filter
(12)                        normalizes integer values and corrects the rounding errors. It
(12)                        doesn't do anything with the source floating point values, it
(12)                        corrects only integers according to the rule of 1.0 which means
(12)                        that any sum of pixel weights must be equal to 1.0.  So, the
(12)                        filter function must produce a graph of the proper shape.
(8)                     filterrad : float > 0, default: 4.0
(12)                        The filter radius for filters that have a radius parameter, i.e.
(12)                        when interpolation is one of: 'sinc', 'lanczos' or 'blackman'.
(8)                     resample : bool, default: :rc:`image.resample`
(12)                        When *True*, use a full resampling method.  When *False*, only
(12)                        resample when the output image is larger than the input image.
(8)                     url : str, optional
(12)                        Set the url of the created `.AxesImage`. See `.Artist.set_url`.
(8)                     Returns
(8)                     -------
(8)                     `~matplotlib.image.AxesImage`
(8)                     Other Parameters
(8)                     ----------------
(8)                     data : indexable object, optional
(12)                        DATA_PARAMETER_PLACEHOLDER
(8)                     **kwargs : `~matplotlib.artist.Artist` properties
(12)                        These parameters are passed on to the constructor of the
(12)                        `.AxesImage` artist.
(8)                     See Also
(8)                     --------
(8)                     matshow : Plot a matrix or an array as an image.
(8)                     Notes
(8)                     -----
(8)                     Unless *extent* is used, pixel centers will be located at integer
(8)                     coordinates. In other words: the origin will coincide with the center
(8)                     of pixel (0, 0).
(8)                     There are two common representations for RGB images with an alpha
(8)                     channel:
```

```
4521: (8)                   -   Straight (unassociated) alpha: R, G, and B channels represent the
4522: (12)                      color of the pixel, disregarding its opacity.
4523: (8)                   -   Premultiplied (associated) alpha: R, G, and B channels represent
4524: (12)                      the color of the pixel, adjusted for its opacity by
multiplication.
4525: (8)                   `~matplotlib.pyplot.imshow` expects RGB images adopting the straight
4526: (8)                   (unassociated) alpha representation.
4527: (8)                   """
4528: (8)                   im = mimage.AxesImage(self, cmap=cmap, norm=norm,

4696: (8)                   %(vmin_vmax_doc)s
4697: (8)                   edgecolors : {'none', None, 'face', color, color sequence}, optional
4698: (12)                      The color of the edges. Defaults to 'none'. Possible values:
4699: (12)                      - 'none' or '': No edge.
4700: (12)                      - *None*: :rc:`patch.edgecolor` will be used. Note that currently
4701: (14)                        :rc:`patch.force_edgecolor` has to be True for this to work.
4702: (12)                      - 'face': Use the adjacent face color.
4703: (12)                      - A color or sequence of colors will set the edge color.
4704: (12)                      The singular form *edgecolor* works as an alias.
4705: (8)                   alpha : float, default: None
4706: (12)                      The alpha blending value of the face color, between 0
(transparent)
4707: (12)                      and 1 (opaque). Note: The edgecolor is currently not affected by
4708: (12)                      this.
4709: (8)                   snap : bool, default: False
4710: (12)                      Whether to snap the mesh to pixel boundaries.
4711: (8)                   Returns
4712: (8)                   -------
4713: (8)                   `matplotlib.collections.PolyQuadMesh`
4714: (8)                   Other Parameters
4715: (8)                   ----------------
4716: (8)                   antialiaseds : bool, default: False
4717: (12)                      The default *antialiaseds* is False if the default
4718: (12)                      *edgecolors*\ ="none" is used.  This eliminates artificial lines
4719: (12)                      at patch boundaries, and works regardless of the value of alpha.
4720: (12)                      If *edgecolors* is not "none", then the default *antialiaseds*
4721: (12)                      is taken from :rc:`patch.antialiased`.
4722: (12)                      Stroking the edges may be preferred if *alpha* is 1, but will
4723: (12)                      cause artifacts otherwise.

        Create a pseudocolor plot with a non-regular rectangular grid.
        Call signature::
            pcolormesh([X, Y,] C, **kwargs)
        *X* and *Y* can be used to specify the corners of the quadrilaterals.
        .. hint::
           `~.Axes.pcolormesh` is similar to `~.Axes.pcolor`. It is much
faster

           and preferred in most cases. For a detailed discussion on the
           differences see :ref:`Differences between pcolor() and pcolormesh()
           <differences-pcolor-pcolormesh>`.
        Parameters
        ----------
        C : array-like
            The mesh data. Supported array shapes are:
            - (M, N) or M*N: a mesh with scalar data. The values are mapped to
              colors using normalization and a colormap. See parameters
*norm*,

              *cmap*, *vmin*, *vmax*.
            - (M, N, 3): an image with RGB values (0-1 float or 0-255 int).
            - (M, N, 4): an image with RGBA values (0-1 float or 0-255 int),
              i.e. including transparency.
            The first two dimensions (M, N) define the rows and columns of
            the mesh data.
        X, Y : array-like, optional
            The coordinates of the corners of quadrilaterals of a pcolormesh::
                (X[i+1, j], Y[i+1, j])       (X[i+1, j+1], Y[i+1, j+1])
                                              ●╶╶╶╶●
                                              ╎     ╎
                                              ●╶╶╶╶●
                        (X[i, j], Y[i, j])       (X[i, j+1], Y[i, j+1])
            Note that the column index corresponds to the x-coordinate, and
            the row index corresponds to y. For details, see the
            :ref:`Notes <axes-pcolormesh-grid-orientation>` section below.
            If ``shading='flat'`` the dimensions of *X* and *Y* should be one
            greater than those of *C*, and the quadrilateral is colored due
            to the value at ``C[i, j]``.  If *X*, *Y* and *C* have equal
            dimensions, a warning will be raised and the last row and column
            of *C* will be ignored.
            If ``shading='nearest'`` or ``'gouraud'``, the dimensions of *X*
            and *Y* should be the same as those of *C* (if not, a ValueError
            will be raised).  For ``'nearest'`` the color ``C[i, j]`` is
            centered on ``(X[i, j], Y[i, j])``.  For ``'gouraud'``, a smooth
            interpolation is carried out between the quadrilateral corners.
            If *X* and/or *Y* are 1-D arrays or column vectors they will be
            expanded as needed into the appropriate 2D arrays, making a
            rectangular grid.
        %(cmap_doc)s
        %(norm_doc)s
        %(vmin_vmax_doc)s
        edgecolors : {'none', None, 'face', color, color sequence}, optional
            The color of the edges. Defaults to 'none'. Possible values:
            - 'none' or '': No edge.
            - *None*: :rc:`patch.edgecolor` will be used. Note that currently
              :rc:`patch.force_edgecolor` has to be True for this to work.
            - 'face': Use the adjacent face color.
            - A color or sequence of colors will set the edge color.
```

```
(12)                    The singular form *edgecolor* works as an alias.
(8)                 alpha : float, default: None
(12)                    The alpha blending value, between 0 (transparent) and 1 (opaque).
(8)                 shading : {'flat', 'nearest', 'gouraud', 'auto'}, optional
(12)                    The fill style for the quadrilateral; defaults to
(12)                    :rc:`pcolor.shading`. Possible values:
(12)                    - 'flat': A solid color is used for each quad. The color of the
(14)                      quad (i, j), (i+1, j), (i, j+1), (i+1, j+1) is given by
(14)                      ``C[i, j]``. The dimensions of *X* and *Y* should be
(14)                      one greater than those of *C*; if they are the same as *C*,
(14)                      then a deprecation warning is raised, and the last row
(14)                      and column of *C* are dropped.
(12)                    - 'nearest': Each grid point will have a color centered on it,
(14)                      extending halfway between the adjacent grid centers.  The
(14)                      dimensions of *X* and *Y* must be the same as *C*.
(12)                    - 'gouraud': Each quad will be Gouraud shaded: The color of the
(14)                      corners (i', j') are given by ``C[i', j']``. The color values of
(14)                      the area in between is interpolated from the corner values.
(14)                      The dimensions of *X* and *Y* must be the same as *C*. When
(14)                      Gouraud shading is used, *edgecolors* is ignored.
(12)                    - 'auto': Choose 'flat' if dimensions of *X* and *Y* are one
(14)                      larger than *C*.  Choose 'nearest' if dimensions are the same.
(12)                    See :doc:`/gallery/images_contours_and_fields/pcolormesh_grids`
(12)                    for more description.
(8)                 snap : bool, default: False
(12)                    Whether to snap the mesh to pixel boundaries.
(8)                 rasterized : bool, optional
(12)                    Rasterize the pcolormesh when drawing vector graphics.  This can
(12)                    speed up rendering and produce smaller files for large data sets.
(12)                    See also :doc:`/gallery/misc/rasterization_demo`.
(8)                 Returns
(8)                 -------
(8)                 `matplotlib.collections.QuadMesh`
(8)                 Other Parameters
(8)                 ----------------
(8)                 data : indexable object, optional
(12)                    DATA_PARAMETER_PLACEHOLDER
(8)                 **kwargs
(12)                    Additionally, the following arguments are allowed. They are passed
(12)                    along to the `~matplotlib.collections.QuadMesh` constructor:
(8)                 %(QuadMesh:kwdoc)s
(8)                 See Also
(8)                 --------
(8)                 pcolor : An alternative implementation with slightly different
(12)                    features. For a detailed discussion on the differences see
(12)                    :ref:`Differences between pcolor() and pcolormesh()
(12)                    <differences-pcolor-pcolormesh>`.
(8)                 imshow : If *X* and *Y* are each equidistant, `~.Axes.imshow` can be a
(12)                    faster alternative.
(8)                 Notes
(8)                 -----
(8)                 **Masked arrays**
(8)                 *C* may be a masked array. If ``C[i, j]`` is masked, the corresponding
(8)                 quadrilateral will be transparent. Masking of *X* and *Y* is not
(8)                 supported. Use `~.Axes.pcolor` if you need this functionality.
(8)                 .. _axes-pcolormesh-grid-orientation:
(8)                 **Grid orientation**
(8)                 The grid orientation follows the standard matrix convention: An array
(8)                 *C* with shape (nrows, ncolumns) is plotted with the column number as
(8)                 *X* and the row number as *Y*.
(8)                 .. _differences-pcolor-pcolormesh:
(8)                 **Differences between pcolor() and pcolormesh()**
(8)                 Both methods are used to create a pseudocolor plot of a 2D array
(8)                 using quadrilaterals.
(8)                 The main difference lies in the created object and internal data
(8)                 handling:
(8)                 While `~.Axes.pcolor` returns a `.PolyQuadMesh`, `~.Axes.pcolormesh`
(8)                 returns a `.QuadMesh`. The latter is more specialized for the given
(8)                 purpose and thus is faster. It should almost always be preferred.
```

```
(8)                 There is also a slight difference in the handling of masked arrays.
(8)                 Both `~.Axes.pcolor` and `~.Axes.pcolormesh` support masked arrays
(8)                 for *C*. However, only `~.Axes.pcolor` supports masked arrays for *X*
(8)                 and *Y*. The reason lies in the internal handling of the masked values.
(8)                 `~.Axes.pcolor` leaves out the respective polygons from the
(8)                 PolyQuadMesh. `~.Axes.pcolormesh` sets the facecolor of the masked
(8)                 elements to transparent. You can see the difference when using
(8)                 edgecolors. While all edges are drawn irrespective of masking in a
(8)                 QuadMesh, the edge between two adjacent masked quadrilaterals in
(8)                 `~.Axes.pcolor` is not drawn as the corresponding polygons do not
(8)                 exist in the PolyQuadMesh. Because PolyQuadMesh draws each individual
(8)                 polygon, it also supports applying hatches and linestyles to the collection.
(8)                 Another difference is the support of Gouraud shading in
(8)                 `~.Axes.pcolormesh`, which is not available with `~.Axes.pcolor`.
(8)                 """

(4)             def pcolorfast(self, *args, alpha=None, norm=None, cmap=None, vmin=None,
(19)                           vmax=None, **kwargs):
(8)                 """
(8)                 Create a pseudocolor plot with a non-regular rectangular grid.
(8)                 Call signature::
(10)                  ax.pcolorfast([X, Y], C, /, **kwargs)
(8)                 This method is similar to `~.Axes.pcolor` and `~.Axes.pcolormesh`.
(8)                 It's designed to provide the fastest pcolor-type plotting with the
(8)                 Agg backend. To achieve this, it uses different algorithms internally
(8)                 depending on the complexity of the input grid (regular rectangular,
(8)                 non-regular rectangular or arbitrary quadrilateral).
(8)                 .. warning::
(11)                   This method is experimental. Compared to `~.Axes.pcolor` or
(11)                   `~.Axes.pcolormesh` it has some limitations:
(11)                   - It supports only flat shading (no outlines)
(11)                   - It lacks support for log scaling of the axes.
(11)                   - It does not have a pyplot wrapper.
(8)                 Parameters
(8)                 ----------
(8)                 C : array-like
```

```
                        The image data. Supported array shapes are:
                        - (M, N): an image with scalar data.  Color-mapping is controlled
                          by *cmap*, *norm*, *vmin*, and *vmax*.
                        - (M, N, 3): an image with RGB values (0-1 float or 0-255 int).
                        - (M, N, 4): an image with RGBA values (0-1 float or 0-255 int),
                          i.e. including transparency.
                        The first two dimensions (M, N) define the rows and columns of
                        the image.
                        This parameter can only be passed positionally.
                    X, Y : tuple or array-like, default: ``(0, N)``, ``(0, M)``
                        *X* and *Y* are used to specify the coordinates of the
                        quadrilaterals. There are different ways to do this:
                        - Use tuples ``X=(xmin, xmax)`` and ``Y=(ymin, ymax)`` to define
                          a *uniform rectangular grid*.
                          The tuples define the outer edges of the grid. All individual
                          quadrilaterals will be of the same size. This is the fastest
                          version.
                        - Use 1D arrays *X*, *Y* to specify a *non-uniform rectangular
                          grid*.
                          In this case *X* and *Y* have to be monotonic 1D arrays of
length

                          *N+1* and *M+1*, specifying the x and y boundaries of the cells.
                          The speed is intermediate. Note: The grid is checked, and if
                          found to be uniform the fast version is used.
                        - Use 2D arrays *X*, *Y* if you need an *arbitrary quadrilateral
                          grid* (i.e. if the quadrilaterals are not rectangular).
                          In this case *X* and *Y* are 2D arrays with shape (M + 1, N +
1),

                          specifying the x and y coordinates of the corners of the colored
                          quadrilaterals.
                          This is the most general, but the slowest to render.  It may
                          produce faster and more compact output using ps, pdf, and
                          svg backends, however.
                        These arguments can only be passed positionally.
                    %(cmap_doc)s
                        This parameter is ignored if *C* is RGB(A).
                    %(norm_doc)s
                        This parameter is ignored if *C* is RGB(A).
                    %(vmin_vmax_doc)s
                        This parameter is ignored if *C* is RGB(A).
                    alpha : float, default: None
                        The alpha blending value, between 0 (transparent) and 1 (opaque).
                    snap : bool, default: False
                        Whether to snap the mesh to pixel boundaries.
                    Returns
                    -------
                    `.AxesImage` or `.PcolorImage` or `.QuadMesh`
                        The return type depends on the type of grid:
                        - `.AxesImage` for a regular rectangular grid.
                        - `.PcolorImage` for a non-regular rectangular grid.
                        - `.QuadMesh` for a non-rectangular grid.
                    Other Parameters
                    ----------------
                    data : indexable object, optional
                        DATA_PARAMETER_PLACEHOLDER
                    **kwargs
                        Supported additional parameters depend on the type of grid.
                        See return types of *image* for further description.
                    """

(4)             def hist(self, x, bins=None, range=None, density=False, weights=None,
(13)                     cumulative=False, bottom=None, histtype='bar', align='mid',
(13)                     orientation='vertical', rwidth=None, log=False,
(13)                     color=None, label=None, stacked=False, **kwargs):
(8)                 """
(8)                 Compute and plot a histogram.
(8)                 This method uses `numpy.histogram` to bin the data in *x* and count
the
(8)                 number of values in each bin, then draws the distribution either as a
(8)                 `.BarContainer` or `.Polygon`. The *bins*, *range*, *density*, and
(8)                 *weights* parameters are forwarded to `numpy.histogram`.
(8)                 If the data has already been binned and counted, use `~.bar` or
(8)                 `~.stairs` to plot the distribution::
(12)                    counts, bins = np.histogram(x)
(12)                    plt.stairs(counts, bins)
(8)                 Alternatively, plot pre-computed bins and counts using ``hist()`` by
(8)                 treating each bin as a single point with a weight equal to its count::
(12)                    plt.hist(bins[:-1], bins, weights=counts)
(8)                 The data input *x* can be a singular array, a list of datasets of
(8)                 potentially different lengths ([*x0*, *x1*, ...]), or a 2D ndarray in
(8)                 which each column is a dataset. Note that the ndarray form is
(8)                 transposed relative to the list form. If the input is an array, then
(8)                 the return value is a tuple (*n*, *bins*, *patches*); if the input is
a
(8)                 sequence of arrays, then the return value is a tuple
(8)                 ([*n0*, *n1*, ...], *bins*, [*patches0*, *patches1*, ...]).
(8)                 Masked arrays are not supported.
(8)                 Parameters
(8)                 ----------
(8)                 x : (n,) array or sequence of (n,) arrays
(12)                    Input values, this takes either a single array or a sequence of
(12)                    arrays which are not required to be of the same length.
(8)                 bins : int or sequence or str, default: :rc:`hist.bins`
(12)                    If *bins* is an integer, it defines the number of equal-width bins
(12)                    in the range.
(12)                    If *bins* is a sequence, it defines the bin edges, including the
(12)                    left edge of the first bin and the right edge of the last bin;
(12)                    in this case, bins may be unequally spaced.  All but the last
(12)                    (righthand-most) bin is half-open.  In other words, if *bins* is::
```

```
(16)                        [1, 2, 3, 4]
(12)                    then the first bin is ``[1, 2)`` (including 1, but excluding 2)
and
(12)                    the second ``[2, 3)``.  The last bin, however, is ``[3, 4]``,
which
(12)                    *includes* 4.
(12)                    If *bins* is a string, it is one of the binning strategies
(12)                    supported by `numpy.histogram_bin_edges`: 'auto', 'fd', 'doane',
(12)                    'scott', 'stone', 'rice', 'sturges', or 'sqrt'.
(8)                 range : tuple or None, default: None
(12)                    The lower and upper range of the bins. Lower and upper outliers
(12)                    are ignored. If not provided, *range* is ``(x.min(), x.max())``.
(12)                    Range has no effect if *bins* is a sequence.
(12)                    If *bins* is a sequence or *range* is specified, autoscaling
(12)                    is based on the specified bin range instead of the
(12)                    range of x.
(8)                 density : bool, default: False
(12)                    If ``True``, draw and return a probability density: each bin
(12)                    will display the bin's raw count divided by the total number of
(12)                    counts *and the bin width*
(12)                    (``density = counts / (sum(counts) * np.diff(bins))``),
(12)                    so that the area under the histogram integrates to 1
(12)                    (``np.sum(density * np.diff(bins)) == 1``).
(12)                    If *stacked* is also ``True``, the sum of the histograms is
(12)                    normalized to 1.
(8)                 weights : (n,) array-like or None, default: None
(12)                    An array of weights, of the same shape as *x*.  Each value in
(12)                    *x* only contributes its associated weight towards the bin count
(12)                    (instead of 1).  If *density* is ``True``, the weights are
(12)                    normalized, so that the integral of the density over the range
(12)                    remains 1.
(8)                 cumulative : bool or -1, default: False
(12)                    If ``True``, then a histogram is computed where each bin gives the
(12)                    counts in that bin plus all bins for smaller values. The last bin
(12)                    gives the total number of datapoints.
(12)                    If *density* is also ``True`` then the histogram is normalized
such
(12)                    that the last bin equals 1.
(12)                    If *cumulative* is a number less than 0 (e.g., -1), the direction
(12)                    of accumulation is reversed.  In this case, if *density* is also
(12)                    ``True``, then the histogram is normalized such that the first bin
(12)                    equals 1.
(8)                 bottom : array-like, scalar, or None, default: None
(12)                    Location of the bottom of each bin, i.e. bins are drawn from
(12)                    ``bottom`` to ``bottom + hist(x, bins)`` If a scalar, the bottom
(12)                    of each bin is shifted by the same amount. If an array, each bin
(12)                    is shifted independently and the length of bottom must match the
(12)                    number of bins. If None, defaults to 0.
(8)                 histtype : {'bar', 'barstacked', 'step', 'stepfilled'}, default: 'bar'
(12)                    The type of histogram to draw.
(12)                    - 'bar' is a traditional bar-type histogram.  If multiple data
(14)                      are given the bars are arranged side by side.
(12)                    - 'barstacked' is a bar-type histogram where multiple
(14)                      data are stacked on top of each other.
(12)                    - 'step' generates a lineplot that is by default unfilled.
(12)                    - 'stepfilled' generates a lineplot that is by default filled.
(8)                 align : {'left', 'mid', 'right'}, default: 'mid'
(12)                    The horizontal alignment of the histogram bars.
(12)                    - 'left': bars are centered on the left bin edges.
(12)                    - 'mid': bars are centered between the bin edges.
(12)                    - 'right': bars are centered on the right bin edges.
(8)                 orientation : {'vertical', 'horizontal'}, default: 'vertical'
(12)                    If 'horizontal', `~.Axes.barh` will be used for bar-type
histograms
(12)                    and the *bottom* kwarg will be the left edges.
(8)                 rwidth : float or None, default: None
(12)                    The relative width of the bars as a fraction of the bin width.  If
(12)                    ``None``, automatically compute the width.
(12)                    Ignored if *histtype* is 'step' or 'stepfilled'.
```

```
(8)                     log : bool, default: False
(12)                        If ``True``, the histogram axis will be set to a log scale.
(8)                     color : :mpltype:`color` or list of :mpltype:`color` or None, default:
None
(12)                        Color or sequence of colors, one per dataset.  Default (``None``)
(12)                        uses the standard line color sequence.
(8)                     label : str or list of str, optional
(12)                        String, or sequence of strings to match multiple datasets.  Bar
(12)                        charts yield multiple patches per dataset, but only the first gets
(12)                        the label, so that `~.Axes.legend` will work as expected.
(8)                     stacked : bool, default: False
(12)                        If ``True``, multiple data are stacked on top of each other If
(12)                        ``False`` multiple data are arranged side by side if histtype is
(12)                        'bar' or on top of each other if histtype is 'step'
(8)                     Returns
(8)                     -------
(8)                     n : array or list of arrays
(12)                        The values of the histogram bins. See *density* and *weights* for
a
(12)                        description of the possible semantics.  If input *x* is an array,
(12)                        then this is an array of length *nbins*. If input is a sequence of
(12)                        arrays ``[data1, data2, ...]``, then this is a list of arrays with
(12)                        the values of the histograms for each of the arrays in the same
(12)                        order.  The dtype of the array *n* (or of its element arrays) will
(12)                        always be float even if no weighting or normalization is used.
(8)                     bins : array
(12)                        The edges of the bins. Length nbins + 1 (nbins left edges and
right
(12)                        edge of last bin).  Always a single array even when multiple data
(12)                        sets are passed in.
(8)                     patches : `.BarContainer` or list of a single `.Polygon` or list of \
(0)             such objects
(12)                        Container of individual artists used to create the histogram
(12)                        or list of such containers if there are multiple input datasets.
(8)                     Other Parameters
(8)                     ----------------
(8)                     data : indexable object, optional
(12)                        DATA_PARAMETER_PLACEHOLDER
(8)                     **kwargs
(12)                        `~matplotlib.patches.Patch` properties
(8)                     See Also
(8)                     --------
(8)                     hist2d : 2D histogram with rectangular bins
(8)                     hexbin : 2D histogram with hexagonal bins
(8)                     stairs : Plot a pre-computed histogram
(8)                     bar : Plot a pre-computed histogram
(8)                     Notes
(8)                     -----
(8)                     For large numbers of bins (>1000), plotting can be significantly
(8)                     accelerated by using `~.Axes.stairs` to plot a pre-computed histogram
(8)                     (``plt.stairs(*np.histogram(data))``), or by setting *histtype* to
(8)                     'step' or 'stepfilled' rather than 'bar' or 'barstacked'.
(8)                     """

(8)                 """
(8)                 Draw a stepwise constant function as a line or a filled plot.
(8)                 *edges* define the x-axis positions of the steps. *values* the
function values
(8)                 between these steps. Depending on *fill*, the function is drawn either
as a
(8)                 continuous line with vertical segments at the edges, or as a filled
area.
(8)                 Parameters
(8)                 ----------
(8)                 values : array-like
(12)                    The step heights.
(8)                 edges : array-like
(12)                    The step positions, with ``len(edges) == len(vals) + 1``,
(12)                    between which the curve takes on vals values.
(8)                 orientation : {'vertical', 'horizontal'}, default: 'vertical'
(12)                    The direction of the steps. Vertical means that *values* are along
(12)                    the y-axis, and edges are along the x-axis.
(8)                 baseline : float, array-like or None, default: 0
(12)                    The bottom value of the bounding edges or when
(12)                    ``fill=True``, position of lower edge. If *fill* is
(12)                    True or an array is passed to *baseline*, a closed
(12)                    path is drawn.
```

```

*x*.
5660: (8)                   .. versionadded:: 3.8
5661: (8)                   Parameters
```

```
    ----------
    x : 1d array-like
        The input data.  Infinite entries are kept (and move the relevant
        end of the ecdf from 0/1), but NaNs and masked values are errors.
    weights : 1d array-like or None, default: None
        The weights of the entries; must have the same shape as *x*.
        Weights corresponding to NaN data points are dropped, and then the
        remaining weights are normalized to sum to 1.  If unset, all
        entries have the same weight.
    complementary : bool, default: False
        Whether to plot a cumulative distribution function, which increases

        from 0 to 1 (the default), or a complementary cumulative
        distribution function, which decreases from 1 to 0.
    orientation : {"vertical", "horizontal"}, default: "vertical"
        Whether the entries are plotted along the x-axis ("vertical", the
        default) or the y-axis ("horizontal").  This parameter takes the
        same values as in `~.Axes.hist`.
    compress : bool, default: False
        Whether multiple entries with the same values are grouped together
        (with a summed weight) before plotting.  This is mainly useful if
        *x* contains many identical data points, to decrease the rendering
        complexity of the plot. If *x* contains no duplicate points, this
        has no effect and just uses some time and memory.
    Other Parameters
    ----------------
    data : indexable object, optional
        DATA_PARAMETER_PLACEHOLDER
    **kwargs
        Keyword arguments control the `.Line2D` properties:
        %(Line2D:kwdoc)s
    Returns
    -------
    `.Line2D`
    Notes
    -----
    The ecdf plot can be thought of as a cumulative histogram with one bin
    per data entry; i.e. it reports on the entire dataset without any
    arbitrary binning.
    If *x* contains NaNs or masked entries, either remove them first from
    the array (if they should not taken into account), or replace them by
    -inf or +inf (if they should be sorted at the beginning or the end of
    the array).

(8)                 r"""
(8)                 Plot the cross-spectral density.
(8)                 The cross spectral density :math:`P_{xy}` by Welch's average
(8)                 periodogram method.  The vectors *x* and *y* are divided into
(8)                 *NFFT* length segments.  Each segment is detrended by function
(8)                 *detrend* and windowed by function *window*.  *noverlap* gives
(8)                 the length of the overlap between segments.  The product of
(8)                 the direct FFTs of *x* and *y* are averaged over each segment
(8)                 to compute :math:`P_{xy}`, with a scaling to correct for power
(8)                 loss due to windowing.
(8)                 If len(*x*) < *NFFT* or len(*y*) < *NFFT*, they will be zero
(8)                 padded to *NFFT*.
(8)                 Parameters
(8)                 ----------
(8)                 x, y : 1-D arrays or sequences
(12)                    Arrays or sequences containing the data.
(8)                 %(Spectral)s
(8)                 %(PSD)s
(8)                 noverlap : int, default: 0 (no overlap)
(12)                    The number of points of overlap between segments.
(8)                 Fc : int, default: 0
(12)                    The center frequency of *x*, which offsets the x extents of the
(12)                    plot to reflect the frequency range used when a signal is acquired
(12)                    and then filtered and downsampled to baseband.
(8)                 return_line : bool, default: False
(12)                    Whether to include the line object plotted in the returned values.
(8)                 Returns
(8)                 -------
(8)                 Pxy : 1-D array
(12)                    The values for the cross spectrum :math:`P_{xy}` before scaling
(12)                    (complex valued).
(8)                 freqs : 1-D array
```

```
(12)                    The frequencies corresponding to the elements in *Pxy*.
(8)                 line : `~matplotlib.lines.Line2D`
(12)                    The line created by this function.
(12)                    Only returned if *return_line* is True.
(8)                 Other Parameters
(8)                 ----------------

(8)                 """
(8)                 Plot a spectrogram.
```

```
(8)                     Compute and plot a spectrogram of data in *x*.  Data are split into
(8)                     *NFFT* length segments and the spectrum of each section is
(8)                     computed.  The windowing function *window* is applied to each
(8)                     segment, and the amount of overlap of each segment is
(8)                     specified with *noverlap*. The spectrogram is plotted as a colormap
(8)                     (using imshow).
(8)                     Parameters
(8)                     ----------
(8)                     x : 1-D array or sequence
(12)                        Array or sequence containing the data.
(8)                     %(Spectral)s
(8)                     %(PSD)s
(8)                     mode : {'default', 'psd', 'magnitude', 'angle', 'phase'}
(12)                        What sort of spectrum to use.  Default is 'psd', which takes the
(12)                        power spectral density.  'magnitude' returns the magnitude
(12)                        spectrum.  'angle' returns the phase spectrum without unwrapping.
(12)                        'phase' returns the phase spectrum with unwrapping.
(8)                     noverlap : int, default: 128
(12)                        The number of points of overlap between blocks.
(8)                     scale : {'default', 'linear', 'dB'}
(12)                        The scaling of the values in the *spec*.  'linear' is no scaling.
(12)                        'dB' returns the values in dB scale.  When *mode* is 'psd',
(12)                        this is dB power (10 * log10).  Otherwise, this is dB amplitude
(12)                        (20 * log10). 'default' is 'dB' if *mode* is 'psd' or
(12)                        'magnitude' and 'linear' otherwise.  This must be 'linear'
(12)                        if *mode* is 'angle' or 'phase'.
(8)                     Fc : int, default: 0
(12)                        The center frequency of *x*, which offsets the x extents of the
(12)                        plot to reflect the frequency range used when a signal is acquired
(12)                        and then filtered and downsampled to baseband.
(8)                     cmap : `.Colormap`, default: :rc:`image.cmap`
(8)                     xextent : *None* or (xmin, xmax)
(12)                        The image extent along the x-axis. The default sets *xmin* to the
(12)                        left border of the first bin (*spectrum* column) and *xmax* to the
(12)                        right border of the last bin. Note that for *noverlap>0* the width
(12)                        of the bins is smaller than those of the segments.
(8)                     data : indexable object, optional
(12)                        DATA_PARAMETER_PLACEHOLDER
(8)                     **kwargs
(12)                        Additional keyword arguments are passed on to `~.axes.Axes.imshow`
(12)                        which makes the specgram image. The origin keyword argument
(12)                        is not supported.
(8)                     Returns
(8)                     -------
(8)                     spectrum : 2D array
(12)                        Columns are the periodograms of successive segments.
(8)                     freqs : 1-D array
(12)                        The frequencies corresponding to the rows in *spectrum*.
(8)                     t : 1-D array
(12)                        The times corresponding to midpoints of segments (i.e., the
columns

(12)                        in *spectrum*).
(8)                     im : `.AxesImage`
(12)                        The image created by imshow containing the spectrogram.
(8)                     See Also
(8)                     --------
(8)                     psd
(12)                        Differs in the default overlap; in returning the mean of the
(12)                        segment periodograms; in not returning times; and in generating a
(12)                        line plot instead of colormap.
(8)                     magnitude_spectrum
(12)                        A single spectrum, similar to having a single segment when *mode*
(12)                        is 'magnitude'. Plots a line instead of a colormap.
(8)                     angle_spectrum
(12)                        A single spectrum, similar to having a single segment when *mode*
(12)                        is 'angle'. Plots a line instead of a colormap.
(8)                     phase_spectrum
(12)                        A single spectrum, similar to having a single segment when *mode*
(12)                        is 'phase'. Plots a line instead of a colormap.

(8)                     """
(8)                     Plot the sparsity pattern of a 2D array.
(8)                     This visualizes the non-zero values of the array.
(8)                     Two plotting styles are available: image and marker. Both
(8)                     are available for full arrays, but only the marker style
(8)                     works for `scipy.sparse.spmatrix` instances.
(8)                     **Image style**
(8)                     If *marker* and *markersize* are *None*, `~.Axes.imshow` is used. Any
(8)                     extra remaining keyword arguments are passed to this method.
(8)                     **Marker style**
(8)                     If *Z* is a `scipy.sparse.spmatrix` or *marker* or *markersize* are
(8)                     *None*, a `.Line2D` object will be returned with the value of marker
(8)                     determining the marker type, and any remaining keyword arguments
(8)                     passed to `~.Axes.plot`.
(8)                     Parameters
(8)                     ----------
```

```
(8)                 Z : (M, N) array-like
(12)                    The array to be plotted.
(8)                 precision : float or 'present', default: 0
(12)                    If *precision* is 0, any non-zero value will be plotted.
Otherwise,

(12)                    values of :math:`|Z| > precision` will be plotted.
(12)                    For `scipy.sparse.spmatrix` instances, you can also
(12)                    pass 'present'. In this case any value present in the array
(12)                    will be plotted, even if it is identically zero.
(8)                 aspect : {'equal', 'auto', None} or float, default: 'equal'
(12)                    The aspect ratio of the Axes.  This parameter is particularly
(12)                    relevant for images since it determines whether data pixels are
(12)                    square.
(12)                    This parameter is a shortcut for explicitly calling
(12)                    `.Axes.set_aspect`. See there for further details.
(12)                    - 'equal': Ensures an aspect ratio of 1. Pixels will be square.
(12)                    - 'auto': The Axes is kept fixed and the aspect is adjusted so
(14)                      that the data fit in the Axes. In general, this will result in
(14)                      non-square pixels.
(12)                    - *None*: Use :rc:`image.aspect`.
(8)                 origin : {'upper', 'lower'}, default: :rc:`image.origin`
(12)                    Place the [0, 0] index of the array in the upper left or lower
left

(12)                    corner of the Axes. The convention 'upper' is typically used for
(12)                    matrices and images.
(8)                 Returns
(8)                 -------
(8)                 `~matplotlib.image.AxesImage` or `.Line2D`

(8)                 Other Parameters
(8)                 ----------------
(8)                 **kwargs
(12)                    The supported additional parameters depend on the plotting style.
(12)                    For the image style, you can pass the following additional
(12)                    parameters of `~.Axes.imshow`:
(12)                    - *cmap*
(12)                    - *alpha*
(12)                    - *url*
(12)                    - any `.Artist` properties (passed on to the `.AxesImage`)
(12)                    For the marker style, you can pass any `.Line2D` property except
(12)                    for *linestyle*:
(12)                    %(Line2D:kwdoc)s
(8)                 """

(8)                 """
(8)                 Make a violin plot.
(8)                 Make a violin plot for each column of *dataset* or each vector in
(8)                 sequence *dataset*.  Each filled area extends to represent the
(8)                 entire data range, with optional lines at the mean, the median,
(8)                 the minimum, the maximum, and user-specified quantiles.
(8)                 Parameters
(8)                 ----------
(8)                 dataset : Array or a sequence of vectors.
(10)                  The input data.
(8)                 positions : array-like, default: [1, 2, ..., n]
(10)                  The positions of the violins; i.e. coordinates on the x-axis for
(10)                  vertical violins (or y-axis for horizontal violins).
(8)                 vert : bool, default: True.
(10)                  If true, creates a vertical violin plot.
(10)                  Otherwise, creates a horizontal violin plot.
(8)                 widths : float or array-like, default: 0.5
(10)                  The maximum width of each violin in units of the *positions* axis.
(10)                  The default is 0.5, which is half the available space when using
default
(10)                  *positions*.
(8)                 showmeans : bool, default: False
(10)                  Whether to show the mean with a line.
(8)                 showextrema : bool, default: True
(10)                  Whether to show extrema with a line.
(8)                 showmedians : bool, default: False
(10)                  Whether to show the median with a line.
(8)                 quantiles : array-like, default: None
(10)                  If not None, set a list of floats in interval [0, 1] for each
violin,
(10)                  which stands for the quantiles that will be rendered for that
(10)                  violin.
(8)                 points : int, default: 100
(10)                  The number of points to evaluate each of the gaussian kernel density
(10)                  estimations at.
(8)                 bw_method : {'scott', 'silverman'} or float or callable, default:
'scott'
(10)                  The method used to calculate the estimator bandwidth.  If a
(10)                  float, this will be used directly as `kde.factor`.  If a
(10)                  callable, it should take a `matplotlib.mlab.GaussianKDE` instance as
(10)                  its only parameter and return a float.
(8)                 side : {'both', 'low', 'high'}, default: 'both'
(12)                    'both' plots standard violins. 'low'/'high' only
(12)                    plots the side below/above the positions value.
(8)                 data : indexable object, optional
(12)                    DATA_PARAMETER_PLACEHOLDER
(8)                 Returns
(8)                 -------
(8)                 dict
(10)                  A dictionary mapping each component of the violinplot to a
(10)                  list of the corresponding collection instances created. The
(10)                  dictionary has the following keys:
(10)                  - ``bodies``: A list of the `~.collections.PolyCollection`
(12)                    instances containing the filled area of each violin.
(10)                  - ``cmeans``: A `~.collections.LineCollection` instance that marks
(12)                    the mean values of each of the violin's distribution.
(10)                  - ``cmins``: A `~.collections.LineCollection` instance that marks
(12)                    the bottom of each violin's distribution.
(10)                  - ``cmaxes``: A `~.collections.LineCollection` instance that marks
(12)                    the top of each violin's distribution.
```

```
  6478: (10)                    - ``cbars``: A `~.collections.LineCollection` instance that marks
  6479: (12)                      the centers of each violin's distribution.
  6480: (10)                    - ``cmedians``: A `~.collections.LineCollection` instance that

  6532: (10)                  The maximum width of each violin in units of the *positions* axis.
  6533: (10)                  The default is 0.5, which is half available space when using default
  6534: (10)                  *positions*.
  6535: (8)                 showmeans : bool, default: False
  6536: (10)                  Whether to show the mean with a line.
  6537: (8)                 showextrema : bool, default: True
  6538: (10)                  Whether to show extrema with a line.
  6539: (8)                 showmedians : bool, default: False
  6540: (10)                  Whether to show the median with a line.
  6541: (8)                 side : {'both', 'low', 'high'}, default: 'both'
  6542: (12)                    'both' plots standard violins. 'low'/'high' only
  6543: (12)                    plots the side below/above the positions value.
  6544: (8)                 Returns
```

```
        -------
        dict
          A dictionary mapping each component of the violinplot to a
          list of the corresponding collection instances created. The
          dictionary has the following keys:
          - ``bodies``: A list of the `~.collections.PolyCollection`
            instances containing the filled area of each violin.
          - ``cmeans``: A `~.collections.LineCollection` instance that marks
            the mean values of each of the violin's distribution.
          - ``cmins``: A `~.collections.LineCollection` instance that marks
            the bottom of each violin's distribution.
          - ``cmaxes``: A `~.collections.LineCollection` instance that marks
            the top of each violin's distribution.
          - ``cbars``: A `~.collections.LineCollection` instance that marks
            the centers of each violin's distribution.
          - ``cmedians``: A `~.collections.LineCollection` instance that
            marks the median values of each of the violin's distribution.
          - ``cquantiles``: A `~.collections.LineCollection` instance created
            to identify the quantiles values of each of the violin's
            distribution.

            _title.set_clip_box(None)
    def set_prop_cycle(self, *args, **kwargs):
        """
        Set the property cycle of the Axes.
        The property cycle controls the style properties such as color,
        marker and linestyle of future plot commands. The style properties
        of data already added to the Axes are not modified.
        Call signatures::
          set_prop_cycle(cycler)
          set_prop_cycle(label=values[, label2=values2[, ...]])
          set_prop_cycle(label, values)
        Form 1 sets given `~cycler.Cycler` object.
        Form 2 creates a `~cycler.Cycler` which cycles over one or more
        properties simultaneously and set it as the property cycle of the
        Axes. If multiple properties are given, their value lists must have
        the same length. This is just a shortcut for explicitly creating a
        cycler and passing it to the function, i.e. it's short for
        ``set_prop_cycle(cycler(label=values, label2=values2, ...))``.
        Form 3 creates a `~cycler.Cycler` for a single property and set it
        as the property cycle of the Axes. This form exists for compatibility
        with the original `cycler.cycler` interface. Its use is discouraged
        in favor of the kwarg form, i.e. ``set_prop_cycle(label=values)``.
        Parameters
        ----------
        cycler : `~cycler.Cycler`
            Set the given Cycler. *None* resets to the cycle defined by the
            current style.
            .. ACCEPTS: `~cycler.Cycler`
        label : str
            The property key. Must be a valid `.Artist` property.
            For example, 'color' or 'linestyle'. Aliases are allowed,
            such as 'c' for 'color' and 'lw' for 'linewidth'.
        values : iterable
            Finite-length iterable of the property values. These values
            are validated and will raise a ValueError if invalid.

(8)                     """
(8)                     Set the aspect ratio of the Axes scaling, i.e. y/x-scale.
(8)                     Parameters
(8)                     ----------
(8)                     aspect : {'auto', 'equal'} or float
(12)                        Possible values:
(12)                        - 'auto': fill the position rectangle with data.
(12)                        - 'equal': same as ``aspect=1``, i.e. same scaling for x and y.
(12)                        - *float*: The displayed size of 1 unit in y-data coordinates will
(14)                          be *aspect* times the displayed size of 1 unit in x-data
(14)                          coordinates; e.g. for ``aspect=2`` a square in data coordinates
(14)                          will be rendered with a height of twice its width.
(8)                     adjustable : None or {'box', 'datalim'}, optional
(12)                        If not ``None``, this defines which parameter will be adjusted to
(12)                        meet the required aspect. See `.set_adjustable` for further
(12)                        details.
(8)                     anchor : None or str or (float, float), optional
(12)                        If not ``None``, this defines where the Axes will be drawn if
there
(12)                        is extra space due to aspect constraints. The most common way
(12)                        to specify the anchor are abbreviations of cardinal directions:

                return ysize / xsize
            def apply_aspect(self, position=None):
                """
                Adjust the Axes for a specified data aspect ratio.
                Depending on `.get_adjustable` this will modify either the
                Axes box (position) or the view limits. In the former case,
                `~matplotlib.axes.Axes.get_anchor` will affect the position.
                Parameters
                ----------
                position : None or .Bbox
                    .. note::
                        This parameter exists for historic reasons and is considered
                        internal. End users should not use it.
                    If not ``None``, this defines the position of the
                    Axes within the figure as a Bbox. See `~.Axes.get_position`
                    for further details.
                Notes
                -----
                This is called automatically when each Axes is drawn.  You may need
                to call it yourself if you need to update the Axes position and/or
                view limits before the Figure is drawn.
                An alternative with a broader scope is `.Figure.draw_without_rendering`,
                which updates all stale components of a figure, not only the positioning /
                view limits of a single Axes.
                See Also
                --------
                matplotlib.axes.Axes.set_aspect
                    For a description of aspect ratio handling.
                matplotlib.axes.Axes.set_adjustable
                    Set how the Axes adjusts to achieve the required aspect ratio.
                matplotlib.axes.Axes.set_anchor
                    Set the position in case of extra space.
                matplotlib.figure.Figure.draw_without_rendering
```

```
(12)                    Update all stale components of a figure.
(8)                 Examples
(8)                 --------
(8)                 A typical usage example would be the following. `~.Axes.imshow` sets the
(8)                 aspect to 1, but adapting the Axes position and extent to reflect this is
(8)                 deferred until rendering for performance reasons. If you want to know the
(8)                 Axes size before, you need to call `.apply_aspect` to get the correct
(8)                 values.
(8)                 >>> fig, ax = plt.subplots()
(8)                 >>> ax.imshow(np.zeros((3, 3)))
(8)                 >>> ax.bbox.width, ax.bbox.height
(8)                 (496.0, 369.59999999999997)
(8)                 >>> ax.apply_aspect()
(8)                 >>> ax.bbox.width, ax.bbox.height
(8)                 (369.59999999999997, 369.59999999999997)
(8)                 """

(8)                 before it is used in autoscaling.  If *m* is negative, this will clip
(8)                 the data range instead of expanding it.
(8)                 For example, if your data is in the range [0, 2], a margin of 0.1 will
(8)                 result in a range [-0.2, 2.2]; a margin of -0.1 will result in a range
(8)                 of [0.2, 1.8].
(8)                 Parameters
(8)                 ----------
(8)                 m : float greater than -0.5
(8)                 """
(8)                 if m <= -0.5:
(12)                    raise ValueError("margin must be greater than -0.5")
(8)                 self._ymargin = m
(8)                 self._request_autoscale_view("y")
(8)                 self.stale = True
(4)             def margins(self, *margins, x=None, y=None, tight=True):
(8)                 """
(8)                 Set or retrieve autoscaling margins.
(8)                 The padding added to each limit of the Axes is the *margin*
(8)                 times the data interval. All input parameters must be floats
(8)                 greater than -0.5. Passing both positional and keyword
(8)                 arguments is invalid and will raise a TypeError. If no
(8)                 arguments (positional or otherwise) are provided, the current
(8)                 margins will remain unchanged and simply be returned.
(8)                 Specifying any margin changes only the autoscaling; for example,
(8)                 if *xmargin* is not None, then *xmargin* times the X data
```

```
        interval will be added to each end of that interval before
        it is used in autoscaling.
        Parameters
        ----------
        *margins : float, optional
            If a single positional argument is provided, it specifies
            both margins of the x-axis and y-axis limits. If two
            positional arguments are provided, they will be interpreted
            as *xmargin*, *ymargin*. If setting the margin on a single
            axis is desired, use the keyword arguments described below.
        x, y : float, optional
            Specific margin values for the x-axis and y-axis,
            respectively. These cannot be used with positional
            arguments, but can be used individually to alter on e.g.,
            only the y-axis.
        tight : bool or None, default: True
            The *tight* parameter is passed to `~.axes.Axes.autoscale_view`,
            which is executed after a margin is changed; the default
            here is *True*, on the assumption that when margins are
            specified, no additional padding to match tick marks is
            usually desired.  Setting *tight* to *None* preserves
            the previous setting.
        Returns
        -------
        xmargin, ymargin : float
        Notes
        -----
        If a previously used Axes method such as :meth:`pcolor` has set
        :attr:`use_sticky_edges` to `True`, only the limits not set by
        the "sticky artists" will be modified. To force all of the
        margins to be set, set :attr:`use_sticky_edges` to `False`
        before calling :meth:`margins`.
        """

(8)                 Configure the `.ScalarFormatter` used by default for linear Axes.
(8)                 If a parameter is not set, the corresponding property of the formatter
(8)                 is left unchanged.
(8)                 Parameters
(8)                 ----------
(8)                 axis : {'x', 'y', 'both'}, default: 'both'
(12)                    The axis to configure.  Only major ticks are affected.
(8)                 style : {'sci', 'scientific', 'plain'}
(12)                    Whether to use scientific notation.
(12)                    The formatter default is to use scientific notation.
(12)                    'sci' is equivalent to 'scientific'.
(8)                 scilimits : pair of ints (m, n)
(12)                    Scientific notation is used only for numbers outside the range
(12)                    10\ :sup:`m` to 10\ :sup:`n` (and only if the formatter is
(12)                    configured to use scientific notation at all).  Use (0, 0) to
(12)                    include all numbers.  Use (m, m) where m != 0 to fix the order of
(12)                    magnitude to 10\ :sup:`m`.
(12)                    The formatter default is :rc:`axes.formatter.limits`.
(8)                 useOffset : bool or float
(12)                    If True, the offset is calculated as needed.
(12)                    If False, no offset is used.
(12)                    If a numeric value, it sets the offset.
(12)                    The formatter default is :rc:`axes.formatter.useoffset`.
(8)                 useLocale : bool
(12)                    Whether to format the number using the current locale or using the
(12)                    C (English) locale.  This affects e.g. the decimal separator.  The
(12)                    formatter default is :rc:`axes.formatter.use_locale`.
(8)                 useMathText : bool
(12)                    Render the offset and scientific notation in mathtext.
(12)                    The formatter default is :rc:`axes.formatter.use_mathtext`.
(8)                 Raises
(8)                 ------
(8)                 AttributeError
(12)                    If the current formatter is not a `.ScalarFormatter`.

(8)                 """
```

```
(8)                     Control behavior of major tick locators.
(8)                     Because the locator is involved in autoscaling,
`~.Axes.autoscale_view`
(8)                     is called automatically after the parameters are changed.
(8)                     Parameters
(8)                     ----------
(8)                     axis : {'both', 'x', 'y'}, default: 'both'
(12)                        The axis on which to operate.  (For 3D Axes, *axis* can also be
(12)                        set to 'z', and 'both' refers to all three axes.)
(8)                     tight : bool or None, optional
(12)                        Parameter passed to `~.Axes.autoscale_view`.
(12)                        Default is None, for no change.
(8)                     Other Parameters
(8)                     ----------------
(8)                     **kwargs
(12)                        Remaining keyword arguments are passed to directly to the
(12)                        ``set_params()`` method of the locator. Supported keywords depend
(12)                        on the type of the locator. See for example
(12)                        `~.ticker.MaxNLocator.set_params` for the `.ticker.MaxNLocator`
(12)                        used by default for linear.
(8)                     Examples
(8)                     --------
(8)                     When plotting small subplots, one might want to reduce the maximum
(8)                     number of ticks and use tight bounds, for example::
(12)                        ax.locator_params(tight=True, nbins=4)
(8)                     """
(8)                     _api.check_in_list([*self._axis_names, "both"], axis=axis)
(8)                     for name in self._axis_names:
(12)                        if axis in [name, "both"]:
(16)                            loc = self._axis_map[name].get_major_locator()
(16)                            loc.set_params(**kwargs)
(16)                            self._request_autoscale_view(name, tight=tight)
(8)                     self.stale = True
(4)                 def tick_params(self, axis='both', **kwargs):
(8)                     """
(8)                     Change the appearance of ticks, tick labels, and gridlines.
(8)                     Tick properties that are not explicitly set using the keyword
(8)                     arguments remain unchanged unless *reset* is True. For the current
(8)                     style settings, see `.Axis.get_tick_params`.
(8)                     Parameters
(8)                     ----------
(8)                     axis : {'x', 'y', 'both'}, default: 'both'
(12)                        The axis to which the parameters are applied.
(8)                     which : {'major', 'minor', 'both'}, default: 'major'
(12)                        The group of ticks to which the parameters are applied.
(8)                     reset : bool, default: False
(12)                        Whether to reset the ticks to defaults before updating them.
(8)                     Other Parameters
(8)                     ----------------
(8)                     direction : {'in', 'out', 'inout'}
(12)                        Puts ticks inside the Axes, outside the Axes, or both.
(8)                     length : float
(12)                        Tick length in points.
(8)                     width : float
(12)                        Tick width in points.
(8)                     color : :mpltype:`color`
(12)                        Tick color.
(8)                     pad : float
(12)                        Distance in points between tick and label.
(8)                     labelsize : float or str
(12)                        Tick label font size in points or as a string (e.g., 'large').
(8)                     labelcolor : :mpltype:`color`
(12)                        Tick label color.
(8)                     labelfontfamily : str
(12)                        Tick label font.
(8)                     colors : :mpltype:`color`
(12)                        Tick color and label color.
(8)                     zorder : float
(12)                        Tick and label zorder.

(12)                    .. ACCEPTS: (bottom: float, top: float)
(8)                 top : float, optional
(12)                    The top ylim in data coordinates. Passing *None* leaves the
(12)                    limit unchanged.
(8)                 emit : bool, default: True
(12)                    Whether to notify observers of limit change.
(8)                 auto : bool or None, default: False
(12)                    Whether to turn on autoscaling of the y-axis. *True* turns on,
(12)                    *False* turns off, *None* leaves unchanged.
(8)                 ymin, ymax : float, optional
(12)                    They are equivalent to bottom and top respectively, and it is an
(12)                    error to pass both *ymin* and *bottom* or *ymax* and *top*.
(8)                 Returns
(8)                 -------
(8)                 bottom, top : (float, float)
(12)                    The new y-axis limits in data coordinates.

```

```
(8)                 Create a new PdfPages object.
(8)                 Parameters
(8)                 ----------
(8)                 filename : str or path-like or file-like
(12)                    Plots using `PdfPages.savefig` will be written to a file at this location.
(12)                    The file is opened when a figure is saved for the first time (overwriting
(12)                    any older file with the same name).
(8)                 keep_empty : bool, optional
(12)                    If set to False, then empty pdf files will be deleted automatically
(12)                    when closed.
(8)                 metadata : dict, optional
(12)                    Information dictionary object (see PDF reference section 10.2.1
(12)                    'Document Information Dictionary'), e.g.:
(12)                    ``{'Creator': 'My software', 'Author': 'Me', 'Title': 'Awesome'}``.
(12)                    The standard keys are 'Title', 'Author', 'Subject', 'Keywords',
(12)                    'Creator', 'Producer', 'CreationDate', 'ModDate', and
(12)                    'Trapped'. Values have been predefined for 'Creator', 'Producer'

(12)                        Output target; if a string, a file will be opened for writing.
(8)                     metadata : dict[str, Any], optional
(12)                        Metadata in the SVG file defined as key-value pairs of strings,
(12)                        datetimes, or lists of strings, e.g., ``{'Creator': 'My software',
(12)                        'Contributor': ['Me', 'My Friend'], 'Title': 'Awesome'}``.
(12)                        The standard keys and their value types are:
(12)                        * *str*: ``'Coverage''``, ``'Description''``, ``'Format''``,
(14)                          ``'Identifier''``, ``'Language''``, ``'Relation''``, ``'Source''``,
(14)                          ``'Title''``, and ``'Type''``.
(12)                        * *str* or *list of str*: ``'Contributor''``, ``'Creator''``,
(14)                          ``'Keywords''``, ``'Publisher''``, and ``'Rights''``.
(12)                        * *str*, *date*, *datetime*, or *tuple* of same: ``'Date''``. If a
(14)                          non-*str*, then it will be formatted as ISO 8601.
(12)                        Values have been predefined for ``'Creator''``, ``'Date''``,
(12)                        ``'Format''``, and ``'Type''``. They can be removed by setting them
(12)                        to `None`.
(12)                        Information is encoded as `Dublin Core Metadata`__.

File 102 - backend_template.py:

```
1: (0)              """
2: (0)              A fully functional, do-nothing backend intended as a template for backend
3: (0)              writers.  It is fully functional in that you can select it as a backend e.g.
4: (0)              with ::
5: (4)                  import matplotlib
6: (4)                  matplotlib.use("template")
7: (0)              and your program will (should!) run without error, though no output is
8: (0)              produced.  This provides a starting point for backend writers; you can
9: (0)              selectively implement drawing methods (`~.RendererTemplate.draw_path`,
10: (0)             `~.RendererTemplate.draw_image`, etc.) and slowly see your figure come to life
11: (0)             instead having to have a full-blown implementation before getting any results.
12: (0)             Copy this file to a directory outside the Matplotlib source tree, somewhere
13: (0)             where Python can import it (by adding the directory to your ``sys.path`` or by
14: (0)             packaging it as a normal Python package); if the backend is importable as
15: (0)             ``import my.backend`` you can then select it using ::
16: (4)                 import matplotlib
17: (4)                 matplotlib.use("module://my.backend")
18: (0)             If your backend implements support for saving figures (i.e. has a `print_xyz`
19: (0)             method), you can register it as the default handler for a given file type::
20: (4)                 from matplotlib.backend_bases import register_backend
21: (4)                 register_backend('xyz', 'my_backend', 'XYZ File Format')
22: (4)                 ...
23: (4)                 plt.savefig("figure.xyz")
24: (0)             """

58: (4)                 The graphics context provides the color, line styles, etc.  See the cairo
59: (4)                 and postscript backends for examples of mapping the graphics context
60: (4)                 attributes (cap styles, join styles, line widths, colors) to a particular
61: (4)                 backend.  In cairo this is done by wrapping a cairo.Context object and
62: (4)                 forwarding the appropriate calls to it using a dictionary mapping styles
63: (4)                 to gdk constants.  In Postscript, all the work is done by the renderer,
64: (4)                 mapping line styles to postscript calls.
65: (4)                 If it's more appropriate to do the mapping at the renderer level (as in
66: (4)                 the postscript backend), you don't need to override any of the GC methods.
67: (4)                 If it's more appropriate to wrap an instance (as in the cairo backend) and
68: (4)                 do the mapping here, you'll need to override several of the setter
69: (4)                 methods.
70: (4)                 The base GraphicsContext stores colors as an RGB tuple on the unit
71: (4)                 interval, e.g., (0.5, 0.0, 1.0). You may need to map this to colors
72: (4)                 appropriate for your backend.
73: (4)                 """
74: (0)             class FigureManagerTemplate(FigureManagerBase):
75: (4)                 """
76: (4)                 Helper class for pyplot mode, wraps everything up into a neat bundle.
77: (4)                 For non-interactive backends, the base class is sufficient.  For
78: (4)                 interactive backends, see the documentation of the `.FigureManagerBase`
79: (4)                 class for the list of methods that can/should be overridden.
80: (4)                 """
81: (0)             class FigureCanvasTemplate(FigureCanvasBase):
82: (4)                 """
83: (4)                 The canvas the figure renders into.  Calls the draw and print fig
84: (4)                 methods, creates the renderers, etc.
85: (4)                 Note: GUI templates will want to connect events for button presses,
86: (4)                 mouse movements and key presses to functions that call the base
87: (4)                 class methods button_press_event, button_release_event,
88: (4)                 motion_notify_event, key_press_event, and key_release_event.  See the
89: (4)                 implementations of the interactive backends for examples.
90: (4)                 Attributes
91: (4)                 ----------
92: (4)                 figure : `~matplotlib.figure.Figure`
93: (8)                     A high-level Figure instance
94: (4)                 """

File 116 - __init__.py:

```
1: (0)              """
2: (0)              Non-separable transforms that map from data space to screen space.
3: (0)              Projections are defined as `~.axes.Axes` subclasses.  They include the
4: (0)              following elements:
5: (0)              - A transformation from data coordinates into display coordinates.
6: (0)              - An inverse of that transformation.  This is used, for example, to convert
7: (2)                mouse positions from screen space back into data space.
8: (0)              - Transformations for the gridlines, ticks and ticklabels.  Custom projections
9: (2)                will often need to place these elements in special locations, and Matplotlib
10: (2)               has a facility to help with doing so.
11: (0)             - Setting up default values (overriding `~.axes.Axes.cla`), since the defaults
12: (2)               for a rectilinear Axes may not be appropriate.
13: (0)             - Defining the shape of the Axes, for example, an elliptical Axes, that will
be
14: (2)               used to draw the background of the plot and for clipping any data elements.
15: (0)             - Defining custom locators and formatters for the projection.  For example, in
16: (2)               a geographic projection, it may be more convenient to display the grid in
17: (2)               degrees, even if the data is in radians.
18: (0)             - Set up interactive panning and zooming.  This is left as an "advanced"
19: (2)               feature left to the reader, but there is an example of this for polar plots
20: (2)               in `matplotlib.projections.polar`.
21: (0)             - Any additional methods for additional convenience or features.
22: (0)             Once the projection Axes is defined, it can be used in one of two ways:
23: (0)             - By defining the class attribute ``name``, the projection Axes can be
24: (2)               registered with `matplotlib.projections.register_projection` and
subsequently
25: (2)               simply invoked by name::
26: (6)                   fig.add_subplot(projection="my_proj_name")
27: (0)             - For more complex, parameterisable projections, a generic "projection" object
28: (2)               may be defined which includes the method ``_as_mpl_axes``. ``_as_mpl_axes``
29: (2)               should take no arguments and return the projection's Axes subclass and a
30: (2)               dictionary of additional arguments to pass to the subclass' ``__init__``
31: (2)               method.  Subsequently a parameterised projection can be initialised with::
32: (6)                   fig.add_subplot(projection=MyProjection(param1=param1_value))
33: (2)               where MyProjection is an object which implements a ``_as_mpl_axes`` method.
34: (0)             A full-fledged and heavily annotated example is in
35: (0)             :doc:`/gallery/misc/custom_projection`.  The polar plot functionality in
36: (0)             `matplotlib.projections.polar` may also be of interest.

File 121 - mathmpl.py:
```

```
1: (0)              r"""
2: (0)              A role and directive to display mathtext in Sphinx
3: (0)              ==================================================
4: (0)              The ``mathmpl`` Sphinx extension creates a mathtext image in Matplotlib and
5: (0)              shows it in html output. Thus, it is a true and faithful representation of
what
6: (0)              you will see if you pass a given LaTeX string to Matplotlib (see
7: (0)              :ref:`mathtext`).
8: (0)              .. warning::
9: (4)                  In most cases, you will likely want to use one of `Sphinx's builtin Math
10: (4)                 extensions
11: (4)                 <https://www.sphinx-doc.org/en/master/usage/extensions/math.html>`__
12: (4)                 instead of this one. The builtin Sphinx math directive uses MathJax to
13: (4)                 render mathematical expressions, and addresses accessibility concerns that
14: (4)                 ``mathmpl`` doesn't address.
15: (0)             Mathtext may be included in two ways:
16: (0)             1. Inline, using the role::
17: (5)                  This text uses inline math: :mathmpl:`\alpha > \beta`.
18: (3)                which produces:
19: (5)                  This text uses inline math: :mathmpl:`\alpha > \beta`.
20: (0)             2. Standalone, using the directive::
21: (5)                  Here is some standalone math:
22: (5)                  .. mathmpl::
23: (9)                      \alpha > \beta
24: (3)                which produces:
25: (5)                  Here is some standalone math:
26: (5)                  .. mathmpl::
27: (9)                      \alpha > \beta
28: (0)             Options
29: (0)             -------
30: (0)             The ``mathmpl`` role and directive both support the following options:
31: (0)             fontset : str, default: 'cm'
32: (4)                 The font set to use when displaying math. See :rc:`mathtext.fontset`.
33: (0)             fontsize : float
34: (4)                 The font size, in points. Defaults to the value from the extension
35: (4)                 configuration option defined below.
36: (0)             Configuration options
37: (0)             ---------------------
38: (0)             The mathtext extension has the following configuration options:
39: (0)             mathmpl_fontsize : float, default: 10.0
40: (4)                 Default font size, in points.
41: (0)             mathmpl_srcset : list of str, default: []
42: (4)                 Additional image sizes to generate when embedding in HTML, to support
43: (4)                 `responsive resolution images
44: (4)                 <https://developer.mozilla.org/en-
US/docs/Learn/HTML/Multimedia_and_embedding/Responsive_images>`__.
45: (4)                 The list should contain additional x-descriptors (``'1.5x'``, ``'2x'``,
46: (4)                 etc.) to generate (1x is the default and always included.)
47: (0)             """

```

File 122 - plot_directive.py:

```
1: (0)              """
2: (0)              A directive for including a Matplotlib plot in a Sphinx document
3: (0)              ================================================================
4: (0)              This is a Sphinx extension providing a reStructuredText directive
5: (0)              ``.. plot::`` for including a plot in a Sphinx document.
6: (0)              In HTML output, ``.. plot::`` will include a .png file with a link
7: (0)              to a high-res .png and .pdf.  In LaTeX output, it will include a .pdf.
8: (0)              The plot content may be defined in one of three ways:
9: (0)              1. **A path to a source file** as the argument to the directive::
10: (5)                  .. plot:: path/to/plot.py
11: (3)                 When a path to a source file is given, the content of the
12: (3)                 directive may optionally contain a caption for the plot::
13: (5)                  .. plot:: path/to/plot.py
14: (8)                     The plot caption.
15: (3)                 Additionally, one may specify the name of a function to call (with
16: (3)                 no arguments) immediately after importing the module::
17: (5)                  .. plot:: path/to/plot.py plot_function1
18: (0)             2. Included as **inline content** to the directive::
19: (5)                  .. plot::
20: (8)                     import matplotlib.pyplot as plt
21: (8)                     plt.plot([1, 2, 3], [4, 5, 6])
```

```
 22: (8)                    plt.title("A plotting exammple")
 23: (0)             3. Using **doctest** syntax::
 24: (5)                  .. plot::
 25: (8)                    A plotting example:
 26: (8)                    >>> import matplotlib.pyplot as plt
 27: (8)                    >>> plt.plot([1, 2, 3], [4, 5, 6])
 28: (0)             Options
 29: (0)             -------
 30: (0)             The ``.. plot::`` directive supports the following options:
 31: (0)             ``:format:`` : {'python', 'doctest'}
 32: (4)                 The format of the input.  If unset, the format is auto-detected.
 33: (0)             ``:include-source:`` : bool
 34: (4)                 Whether to display the source code. The default can be changed using
 35: (4)                 the ``plot_include_source`` variable in :file:`conf.py` (which itself
 36: (4)                 defaults to False).
 37: (0)             ``:show-source-link:`` : bool
 38: (4)                 Whether to show a link to the source in HTML. The default can be
 39: (4)                 changed using the ``plot_html_show_source_link`` variable in
 40: (4)                 :file:`conf.py` (which itself defaults to True).
 41: (0)             ``:context:`` : bool or str
 42: (4)                 If provided, the code will be run in the context of all previous plot
 43: (4)                 directives for which the ``:context:`` option was specified.  This only
 44: (4)                 applies to inline code plot directives, not those run from files. If
 45: (4)                 the ``:context: reset`` option is specified, the context is reset
 46: (4)                 for this and future plots, and previous figures are closed prior to
 47: (4)                 running the code. ``:context: close-figs`` keeps the context but closes
 48: (4)                 previous figures before running the code.
 49: (0)             ``:nofigs:`` : bool
 50: (4)                 If specified, the code block will be run, but no figures will be
 51: (4)                 inserted.  This is usually useful with the ``:context:`` option.
 52: (0)             ``:caption:`` : str
 53: (4)                 If specified, the option's argument will be used as a caption for the
 54: (4)                 figure. This overwrites the caption given in the content, when the plot
 55: (4)                 is generated from a file.
 56: (0)             Additionally, this directive supports all the options of the `image directive
 57: (0)             <https://docutils.sourceforge.io/docs/ref/rst/directives.html#image>`_,
 58: (0)             except for ``:target:`` (since plot will add its own target).  These include
 59: (0)             ``:alt:``, ``:height:``, ``:width:``, ``:scale:``, ``:align:`` and
``:class:``.
 60: (0)             Configuration options
 61: (0)             ---------------------
 62: (0)             The plot directive has the following configuration options:
 63: (0)             plot_include_source
 64: (4)                 Default value for the include-source option (default: False).
 65: (0)             plot_html_show_source_link
 66: (4)                 Whether to show a link to the source in HTML (default: True).
 67: (0)             plot_pre_code
 68: (4)                 Code that should be executed before each plot. If None (the default),
 69: (4)                 it will default to a string containing::
 70: (8)                     import numpy as np
 71: (8)                     from matplotlib import pyplot as plt
 72: (0)             plot_basedir
 73: (4)                 Base directory, to which ``plot::`` file names are relative to.
 74: (4)                 If None or empty (the default), file names are relative to the
 75: (4)                 directory where the file containing the directive is.
 76: (0)             plot_formats
 77: (4)                 File formats to generate (default: ['png', 'hires.png', 'pdf']).
 78: (4)                 List of tuples or strings::
 79: (8)                     [(suffix, dpi), suffix, ...]
 80: (4)                 that determine the file format and the DPI. For entries whose
 81: (4)                 DPI was omitted, sensible defaults are chosen. When passing from
 82: (4)                 the command line through sphinx_build the list should be passed as
 83: (4)                 suffix:dpi,suffix:dpi, ...
 84: (0)             plot_html_show_formats
 85: (4)                 Whether to show links to the files in HTML (default: True).
 86: (0)             plot_rcparams
 87: (4)                 A dictionary containing any non-standard rcParams that should
 88: (4)                 be applied before each plot (default: {}).
 89: (0)             plot_apply_rcparams
```

```
90: (4)                 By default, rcParams are applied when ``:context:`` option is not used
91: (4)                 in a plot directive.  If set, this configuration option overrides this
92: (4)                 behavior and applies rcParams before each plot.
93: (0)             plot_working_directory
94: (4)                 By default, the working directory will be changed to the directory of
95: (4)                 the example, so the code can get at its data files, if any.  Also its
96: (4)                 path will be added to `sys.path` so it can import any helper modules
97: (4)                 sitting beside it.  This configuration option can be used to specify
98: (4)                 a central directory (also added to `sys.path`) where data files and
99: (4)                 helper modules for all code are located.
100: (0)            plot_template
101: (4)                Provide a customized template for preparing restructured text.
102: (0)            plot_srcset
103: (4)                Allow the srcset image option for responsive image resolutions. List of
104: (4)                strings with the multiplicative factors followed by an "x".
105: (4)                e.g. ["2.0x", "1.5x"].  "2.0x" will create a png with the default "png"
106: (4)                resolution from plot_formats, multiplied by 2. If plot_srcset is
107: (4)                specified, the plot directive uses the
108: (4)                :doc:`/api/sphinxext_figmpl_directive_api` (instead of the usual figure
109: (4)                directive) in the intermediary rst file that is generated.
110: (4)                The plot_srcset option is incompatible with *singlehtml* builds, and an
111: (4)                error will be raised.
112: (0)            Notes on how it works
113: (0)            ---------------------
114: (0)            The plot directive runs the code it is given, either in the source file or the
115: (0)            code under the directive. The figure created (if any) is saved in the sphinx
116: (0)            build directory under a subdirectory named ``plot_directive``.  It then
creates
117: (0)            an intermediate rst file that calls a ``.. figure:`` directive (or
118: (0)            ``.. figmpl::`` directive if ``plot_srcset`` is being used) and has links to
119: (0)            the ``*.png`` files in the ``plot_directive`` directory.  These translations
can
120: (0)            be customized by changing the *plot_template*.  See the source of
121: (0)            :doc:`/api/sphinxext_plot_directive_api` for the templates defined in
*TEMPLATE*
122: (0)            and *TEMPLATE_SRCSET*.
123: (0)            """

File 123 - roles.py:

```
1: (0)              """
2: (0)              Custom roles for the Matplotlib documentation.
3: (0)              .. warning::
4: (4)                  These roles are considered semi-public. They are only intended to be used
in
5: (4)                  the Matplotlib documentation.
6: (0)              However, it can happen that downstream packages end up pulling these roles
into
7: (0)              their documentation, which will result in documentation build errors. The
following
8: (0)              describes the exact mechanism and how to fix the errors.
9: (0)              There are two ways, Matplotlib docstrings can end up in downstream
documentation.
10: (0)             You have to subclass a Matplotlib class and either use the ``:inherited-
members:``
11: (0)             option in your autodoc configuration, or you have to override a method without
12: (0)             specifying a new docstring; the new method will inherit the original docstring
and
13: (0)             still render in your autodoc. If the docstring contains one of the custom
sphinx
14: (0)             roles, you'll see one of the following error messages:
15: (0)             .. code-block:: none
16: (4)                 Unknown interpreted text role "mpltype".
17: (4)                 Unknown interpreted text role "rc".
18: (0)             To fix this, you can add this module as extension to your sphinx
:file:`conf.py`::
19: (4)                 extensions = [
20: (8)                     'matplotlib.sphinxext.roles',
21: (4)                 ]
22: (0)             .. warning::
23: (4)                 Direct use of these roles in other packages is not officially supported.
We
24: (4)                 reserve the right to modify or remove these roles without prior
notification.
25: (0)             """

41: (4)                 The style name of 'default' is reserved for reverting back to
42: (4)                 the default style settings.
43: (4)                 .. note::
44: (7)                    This updates the `.rcParams` with the settings from the style.
45: (7)                    `.rcParams` not defined in the style are kept.
46: (4)                 Parameters
47: (4)                 ----------
48: (4)                 style : str, dict, Path or list
49: (8)                     A style specification. Valid options are:
50: (8)                     str
51: (12)                        - One of the style names in `.style.available` (a builtin style or
52: (14)                          a style installed in the user library path).
53: (12)                        - A dotted name of the form "package.style_name"; in that case,
54: (14)                          "package" should be an importable Python package name, e.g. at
55: (14)                          ``/path/to/package/__init__.py``; the loaded style file is
56: (14)                          ``/path/to/package/style_name.mplstyle``.  (Style files in
57: (14)                          subpackages are likewise supported.)
58: (12)                        - The path or URL to a style file, which gets loaded by
59: (14)                          `.rc_params_from_file`.
60: (8)                     dict
61: (12)                        A mapping of key/value pairs for `matplotlib.rcParams`.
62: (8)                     Path
63: (12)                        The path to a style file, which gets loaded by
64: (12)                        `.rc_params_from_file`.
65: (8)                     list
66: (12)                        A list of style specifiers (str, Path or dict), which are applied
67: (12)                        from first to last in the list.
68: (4)                 Notes
69: (4)                 -----
70: (4)                 The following `.rcParams` are not related to style and will be ignored if
71: (4)                 found in a style specification:
72: (4)                 %s
73: (4)                 """

(4)                 Context manager for using style settings temporarily.
(4)                 Parameters
(4)                 ----------
(4)                 style : str, dict, Path or list
(8)                     A style specification. Valid options are:
(8)                     str
(12)                        - One of the style names in `.style.available` (a builtin style or
(14)                          a style installed in the user library path).
(12)                        - A dotted name of the form "package.style_name"; in that case,
(14)                          "package" should be an importable Python package name, e.g. at
(14)                          ``/path/to/package/__init__.py``; the loaded style file is
(14)                          ``/path/to/package/style_name.mplstyle``.  (Style files in
(14)                          subpackages are likewise supported.)
(12)                        - The path or URL to a style file, which gets loaded by
(14)                          `.rc_params_from_file`.
(8)                     dict
(12)                        A mapping of key/value pairs for `matplotlib.rcParams`.
(8)                     Path
(12)                        The path to a style file, which gets loaded by
(12)                        `.rc_params_from_file`.
(8)                     list
(12)                        A list of style specifiers (str, Path or dict), which are applied
(12)                        from first to last in the list.
(4)                 after_reset : bool
(8)                     If True, apply style after resetting settings to their defaults;
(8)                     otherwise, apply style on top of the current settings.

210: (4)                exception will be raised.
211: (4)                Parameters
212: (4)                ----------
213: (4)                baseline_images : list or None
214: (8)                    A list of strings specifying the names of the images generated by
215: (8)                    calls to `.Figure.savefig`.
```

```
(8)                 If *None*, the test function must use the ``baseline_images`` fixture,
(8)                 either as a parameter or with `pytest.mark.usefixtures`. This value is
(8)                 only allowed when using pytest.
(4)             extensions : None or list of str
(8)                 The list of extensions to test, e.g. ``['png', 'pdf']``.
(8)                 If *None*, defaults to all supported extensions: png, pdf, and svg.
(8)                 When testing a single extension, it can be directly included in the
(8)                 names passed to *baseline_images*.  In that case, *extensions* must
not
(8)                 be set.
(8)                 In order to keep the size of the test suite from ballooning, we only
(8)                 include the ``svg`` or ``pdf`` outputs if the test is explicitly
(8)                 exercising a feature dependent on that backend (see also the
(8)                 `check_figures_equal` decorator for that purpose).
(4)             tol : float, default: 0
(8)                 The RMS threshold above which the test is considered failed.
(8)                 Due to expected small differences in floating-point calculations, on
(8)                 32-bit systems an additional 0.06 is added to this threshold.
(4)             freetype_version : str or tuple
(8)                 The expected freetype version or range of versions for this test to
(8)                 pass.
(4)             remove_text : bool
(8)                 Remove the title and tick text from the figure before comparison.
This
(8)                 is useful to make the baseline images independent of variations in
text
(8)                 rendering between different versions of FreeType.
(8)                 This does not remove other, more deliberate, text, such as legends and
(8)                 annotations.
(4)             savefig_kwarg : dict
(8)                 Optional arguments that are passed to the savefig method.
(4)             style : str, dict, or list
(8)                 The optional style(s) to apply to the image test. The test itself
(8)                 can also apply additional styles if desired. Defaults to ``["classic",
(8)                 "_classic_test_patch"]``.

----------------------------------------

File 133 - __init__.py:
```

```
1: (0)              """
2: (0)              A sample set of units for use with testing unit conversion
3: (0)              of Matplotlib routines.  These are used because they use very strict
4: (0)              enforcement of unitized data which will test the entire spectrum of how
5: (0)              unitized data might be used (it is not always meaningful to convert to
6: (0)              a float without specific units given).
7: (0)              UnitDbl is essentially a unitized floating point number.  It has a
8: (0)              minimal set of supported units (enough for testing purposes).  All
9: (0)              of the mathematical operation are provided to fully test any behaviour
10: (0)             that might occur with unitized data.  Remember that unitized data has
11: (0)             rules as to how it can be applied to one another (a value of distance
12: (0)             cannot be added to a value of time).  Thus we need to guard against any
13: (0)             accidental "default" conversion that will strip away the meaning of the
14: (0)             data and render it neutered.
15: (0)             Epoch is different than a UnitDbl of time.  Time is something that can be
16: (0)             measured where an Epoch is a specific moment in time.  Epochs are typically
17: (0)             referenced as an offset from some predetermined epoch.
18: (0)             A difference of two epochs is a Duration.  The distinction between a Duration
19: (0)             and a UnitDbl of time is made because an Epoch can have different frames (or
20: (0)             units).  In the case of our test Epoch class the two allowed frames are 'UTC'
21: (0)             and 'ET' (Note that these are rough estimates provided for testing purposes
22: (0)             and should not be used in production code where accuracy of time frames is
23: (0)             desired).  As such a Duration also has a frame of reference and therefore
needs
24: (0)             to be called out as different that a simple measurement of time since a delta-
t
25: (0)             in one frame may not be the same in another.
