67: (0)             _docstring.interpd.update(_tricontour_doc="""
68: (0)             Draw contour %%(type)s on an unstructured triangular grid.
69: (0)             Call signatures::
70: (4)                 %%(func)s(triangulation, z, [levels], ...)
71: (4)                 %%(func)s(x, y, z, [levels], *, [triangles=triangles], [mask=mask], ...)
72: (0)             The triangular grid can be specified either by passing a `.Triangulation`
73: (0)             object as the first parameter, or by passing the points *x*, *y* and
74: (0)             optionally the *triangles* and a *mask*. See `.Triangulation` for an
75: (0)             explanation of these parameters. If neither of *triangulation* or
76: (0)             *triangles* are given, the triangulation is calculated on the fly.
77: (0)             It is possible to pass *triangles* positionally, i.e.
78: (0)             ``%%(func)s(x, y, triangles, z, ...)``. However, this is discouraged. For more
79: (0)             clarity, pass *triangles* via keyword argument.
80: (0)             Parameters
81: (0)             ----------
82: (0)             triangulation : `.Triangulation`, optional
83: (4)                 An already created triangular grid.
84: (0)             x, y, triangles, mask
85: (4)                 Parameters defining the triangular grid. See `.Triangulation`.
86: (4)                 This is mutually exclusive with specifying *triangulation*.
87: (0)             z : array-like
88: (4)                 The height values over which the contour is drawn.  Color-mapping is

90: (4)                 .. note::
91: (8)                     All values in *z* must be finite. Hence, nan and inf values must
92: (8)                     either be removed or `~.Triangulation.set_mask` be used.
93: (0)             levels : int or array-like, optional
94: (4)                 Determines the number and positions of the contour lines / regions.
95: (4)                 If an int *n*, use `~matplotlib.ticker.MaxNLocator`, which tries to
96: (4)                 automatically choose no more than *n+1* "nice" contour levels between
97: (4)                 between minimum and maximum numeric values of *Z*.
98: (4)                 If array-like, draw contour lines at the specified levels.  The values
must
99: (4)                 be in increasing order.
100: (0)            Returns
101: (0)            -------
102: (0)            `~matplotlib.tri.TriContourSet`
103: (0)            Other Parameters
104: (0)            ----------------
105: (0)            colors : :mpltype:`color` or list of :mpltype:`color`, optional
106: (4)                The colors of the levels, i.e., the contour %%(type)s.
107: (4)                The sequence is cycled for the levels in ascending order. If the sequence
108: (4)                is shorter than the number of levels, it is repeated.
109: (4)                As a shortcut, single color strings may be used in place of one-element
110: (4)                lists, i.e. ``'red'`` instead of ``['red']`` to color all levels with the
111: (4)                same color. This shortcut does only work for color strings, not for other
112: (4)                ways of specifying colors.
113: (4)                By default (value *None*), the colormap specified by *cmap* will be used.

116: (0)            %(cmap_doc)s
117: (4)                This parameter is ignored if *colors* is set.
118: (0)            %(norm_doc)s
119: (4)                This parameter is ignored if *colors* is set.
```

```
(0)             %(vmin_vmax_doc)s
(4)                 If *vmin* or *vmax* are not given, the default color scaling is based on
(4)                 *levels*.
(4)                 This parameter is ignored if *colors* is set.
(0)             origin : {*None*, 'upper', 'lower', 'image'}, default: None
(4)                 Determines the orientation and exact position of *z* by specifying the
(4)                 position of ``z[0, 0]``.  This is only relevant, if *X*, *Y* are not
given.
(4)                 - *None*: ``z[0, 0]`` is at X=0, Y=0 in the lower left corner.
(4)                 - 'lower': ``z[0, 0]`` is at X=0.5, Y=0.5 in the lower left corner.
(4)                 - 'upper': ``z[0, 0]`` is at X=N+0.5, Y=0.5 in the upper left corner.
(4)                 - 'image': Use the value from :rc:`image.origin`.
(0)             extent : (x0, x1, y0, y1), optional
(4)                 If *origin* is not *None*, then *extent* is interpreted as in `.imshow`:
it
(4)                 gives the outer pixel boundaries. In this case, the position of z[0, 0] is
(4)                 the center of the pixel, not a corner. If *origin* is *None*, then
(4)                 (*x0*, *y0*) is the position of z[0, 0], and (*x1*, *y1*) is the position
(4)                 of z[-1, -1].
(4)                 This argument is ignored if *X* and *Y* are specified in the call to
(4)                 contour.
(0)             locator : ticker.Locator subclass, optional
(4)                 The locator is used to determine the contour levels if they are not given
(4)                 explicitly via *levels*.
(4)                 Defaults to `~.ticker.MaxNLocator`.
(0)             extend : {'neither', 'both', 'min', 'max'}, default: 'neither'
(4)                 Determines the ``%%(func)s``-coloring of values that are outside the
(4)                 *levels* range.
(4)                 If 'neither', values outside the *levels* range are not colored.  If
'min',
(4)                 'max' or 'both', color the values below, above or below and above the
(4)                 *levels* range.
(4)                 Values below ``min(levels)`` and above ``max(levels)`` are mapped to the
(4)                 under/over values of the `.Colormap`. Note that most colormaps do not have
(4)                 dedicated colors for these by default, so that the over and under values
(4)                 are the edge values of the colormap.  You may want to set these values
(4)                 explicitly using `.Colormap.set_under` and `.Colormap.set_over`.
(4)                 .. note::
(8)                     An existing `.TriContourSet` does not get notified if properties of
its
(8)                     colormap are changed. Therefore, an explicit call to
(8)                     `.ContourSet.changed()` is needed after modifying the colormap. The
(8)                     explicit call can be left out, if a colorbar is assigned to the
(8)                     `.TriContourSet` because it internally calls `.ContourSet.changed()`.
(0)             xunits, yunits : registered units, optional
(4)                 Override axis units by specifying an instance of a
(4)                 :class:`matplotlib.units.ConversionInterface`.
(0)             antialiased : bool, optional
(4)                 Enable antialiasing, overriding the defaults.  For
(4)                 filled contours, the default is *True*.  For line contours,
(4)                 it is taken from :rc:`lines.antialiased`."""% _docstring.interpd.params)
(0)             @_docstring.Substitution(func='tricontour', type='lines')
(0)             @_docstring.dedent_interpd
(0)             def tricontour(ax, *args, **kwargs):
(4)                 """
(4)                 %(_tricontour_doc)s
(4)                 linewidths : float or array-like, default: :rc:`contour.linewidth`
(8)                     The line width of the contour lines.
(8)                     If a number, all levels will be plotted with this linewidth.
(8)                     If a sequence, the levels in ascending order will be plotted with
(8)                     the linewidths in the order specified.
(8)                     If None, this falls back to :rc:`lines.linewidth`.
(4)                 linestyles : {*None*, 'solid', 'dashed', 'dashdot', 'dotted'}, optional
(8)                     If *linestyles* is *None*, the default is 'solid' unless the lines are
(8)                     monochrome.  In that case, negative contours will take their linestyle
(8)                     from :rc:`contour.negative_linestyle` setting.
(8)                     *linestyles* can also be an iterable of the above strings specifying a
(8)                     set of linestyles to be used. If this iterable is shorter than the
(8)                     number of contour levels it will be repeated as necessary.

(8)                     """
(8)                     Versatile (private) method defined for all TriInterpolators.
(8)                     :meth:`_interpolate_multikeys` is a wrapper around method
(8)                     :meth:`_interpolate_single_key` (to be defined in the child
(8)                     subclasses).
(8)                     :meth:`_interpolate_single_key actually performs the interpolation,
(8)                     but only for 1-dimensional inputs and at valid locations (inside
(8)                     unmasked triangles of the triangulation).
(8)                     The purpose of :meth:`_interpolate_multikeys` is to implement the
(8)                     following common tasks needed in all subclasses implementations:
(8)                     - calculation of containing triangles
(8)                     - dealing with more than one interpolation request at the same
(10)                      location (e.g., if the 2 derivatives are requested, it is
(10)                      unnecessary to compute the containing triangles twice)
(8)                     - scaling according to self._unit_x, self._unit_y
(8)                     - dealing with points outside of the grid (with fill value np.nan)
(8)                     - dealing with multi-dimensional *x*, *y* arrays: flattening for
(10)                      :meth:`_interpolate_params` call and final reshaping.
(8)                     (Note that np.vectorize could do most of those things very well for
(8)                     you, but it does it by function evaluations over successive tuples of
(8)                     the input arrays. Therefore, this tends to be more time-consuming than
(8)                     using optimized numpy functions - e.g., np.dot - which can be used
(8)                     easily on the flattened inputs, in the child-subclass methods
(8)                     :meth:`_interpolate_single_key`.)
(8)                     It is guaranteed that the calls to :meth:`_interpolate_single_key`
(8)                     will be done with flattened (1-d) array-like input parameters *x*, *y*
```

```
 96: (8)                    and with flattened, valid `tri_index` arrays (no -1 index allowed).
 97: (8)                    Parameters
 98: (8)                    ----------
 99: (8)                    x, y : array-like
100: (12)                       x and y coordinates where interpolated values are requested.
101: (8)                    tri_index : array-like of int, optional
102: (12)                       Array of the containing triangle indices, same shape as
103: (12)                       *x* and *y*. Defaults to None. If None, these indices
104: (12)                       will be computed by a TriFinder instance.
105: (12)                       (Note: For point outside the grid, tri_index[ipt] shall be -1).
106: (8)                    return_keys : tuple of keys from {'z', 'dzdx', 'dzdy'}
107: (12)                       Defines the interpolation arrays to return, and in which order.
108: (8)                    Returns
109: (8)                    -------
110: (8)                    list of arrays
111: (12)                       Each array-like contains the expected interpolated values in the
112: (12)                       order defined by *return_keys* parameter.

(0)         class CubicTriInterpolator(TriInterpolator):
(4)             r"""
(4)             Cubic interpolator on a triangular grid.
(4)             In one-dimension - on a segment - a cubic interpolating function is
(4)             defined by the values of the function and its derivative at both ends.
(4)             This is almost the same in 2D inside a triangle, except that the values
(4)             of the function and its 2 derivatives have to be defined at each triangle
(4)             node.
(4)             The CubicTriInterpolator takes the value of the function at each node -
(4)             provided by the user - and internally computes the value of the
(4)             derivatives, resulting in a smooth interpolation.
(4)             (As a special feature, the user can also impose the value of the
(4)             derivatives at each node, but this is not supposed to be the common
(4)             usage.)
(4)             Parameters
(4)             ----------
(4)             triangulation : `~matplotlib.tri.Triangulation`
```

```
(8)                 The triangulation to interpolate over.
(4)             z : (npoints,) array-like
(8)                 Array of values, defined at grid points, to interpolate between.
(4)             kind : {'min_E', 'geom', 'user'}, optional
(8)                 Choice of the smoothing algorithm, in order to compute
(8)                 the interpolant derivatives (defaults to 'min_E'):
(8)                 - if 'min_E': (default) The derivatives at each node is computed
(10)                  to minimize a bending energy.
(8)                 - if 'geom': The derivatives at each node is computed as a
(10)                  weighted average of relevant triangle normals. To be used for
(10)                  speed optimization (large grids).
(8)                 - if 'user': The user provides the argument *dz*, no computation
(10)                  is hence needed.
(4)             trifinder : `~matplotlib.tri.TriFinder`, optional
(8)                 If not specified, the Triangulation's default TriFinder will
(8)                 be used by calling `.Triangulation.get_trifinder`.
(4)             dz : tuple of array-likes (dzdx, dzdy), optional
(8)                 Used only if  *kind* ='user'. In this case *dz* must be provided as
(8)                 (dzdx, dzdy) where dzdx, dzdy are arrays of the same shape as *z* and
(8)                 are the interpolant first derivatives at the *triangulation* points.
(4)             Methods
(4)             -------
(4)             `__call__` (x, y) : Returns interpolated values at (x, y) points.
(4)             `gradient` (x, y) : Returns interpolated derivatives at (x, y) points.
(4)             Notes
(4)             -----
(4)             This note is a bit technical and details how the cubic interpolation is
(4)             computed.
(4)             The interpolation is based on a Clough-Tocher subdivision scheme of
(4)             the *triangulation* mesh (to make it clearer, each triangle of the
(4)             grid will be divided in 3 child-triangles, and on each child triangle
(4)             the interpolated function is a cubic polynomial of the 2 coordinates).
(4)             This technique originates from FEM (Finite Element Method) analysis;
(4)             the element used is a reduced Hsieh-Clough-Tocher (HCT)
(4)             element. Its shape functions are described in [1]_.
(4)             The assembled function is guaranteed to be C1-smooth, i.e. it is
(4)             continuous and its first derivatives are also continuous (this
(4)             is easy to show inside the triangles but is also true when crossing the
(4)             edges).
(4)             In the default case (*kind* ='min_E'), the interpolant minimizes a
(4)             curvature energy on the functional space generated by the HCT element
(4)             shape functions - with imposed values but arbitrary derivatives at each
(4)             node. The minimized functional is the integral of the so-called total
(4)             curvature (implementation based on an algorithm from [2]_ - PCG sparse
(4)             solver):
(4)             .. math::
(8)                 E(z) = \frac{1}{2} \int_{\Omega} \left(
(12)                    \left( \frac{\partial^2{z}}{\partial{x}^2} \right)^2 +
(12)                    \left( \frac{\partial^2{z}}{\partial{y}^2} \right)^2 +
(12)                    2\left( \frac{\partial^2{z}}{\partial{y}\partial{x}} \right)^2
(8)                 \right) dx\,dy
(4)             If the case *kind* ='geom' is chosen by the user, a simple geometric
(4)             approximation is used (weighted average of the triangle normal
(4)             vectors), which could improve speed on very large grids.

7: (4)                  """
8: (4)                  Create a pseudocolor plot of an unstructured triangular grid.
9: (4)                  Call signatures::
10: (6)                   tripcolor(triangulation, c, *, ...)
11: (6)                   tripcolor(x, y, c, *, [triangles=triangles], [mask=mask], ...)
12: (4)                 The triangular grid can be specified either by passing a `.Triangulation`
13: (4)                 object as the first parameter, or by passing the points *x*, *y* and
14: (4)                 optionally the *triangles* and a *mask*. See `.Triangulation` for an
15: (4)                 explanation of these parameters.
16: (4)                 It is possible to pass the triangles positionally, i.e.
17: (4)                 ``tripcolor(x, y, triangles, c, ...)``. However, this is discouraged.
18: (4)                 For more clarity, pass *triangles* via keyword argument.
19: (4)                 If neither of *triangulation* or *triangles* are given, the triangulation
20: (4)                 is calculated on the fly. In this case, it does not make sense to provide
21: (4)                 colors at the triangle faces via *c* or *facecolors* because there are
22: (4)                 multiple possible triangulations for a group of points and you don't know
23: (4)                 which triangles will be constructed.
24: (4)                 Parameters
25: (4)                 ----------
26: (4)                 triangulation : `.Triangulation`
27: (8)                     An already created triangular grid.
28: (4)                 x, y, triangles, mask
29: (8)                     Parameters defining the triangular grid. See `.Triangulation`.
30: (8)                     This is mutually exclusive with specifying *triangulation*.
31: (4)                 c : array-like
32: (8)                     The color values, either for the points or for the triangles. Which
one
33: (8)                     is automatically inferred from the length of *c*, i.e. does it match
34: (8)                     the number of points or the number of triangles. If there are the same
35: (8)                     number of points and triangles in the triangulation it is assumed that
36: (8)                     color values are defined at points; to force the use of color values
at
37: (8)                     triangles use the keyword argument ``facecolors=c`` instead of just
38: (8)                     ``c``.
39: (8)                     This parameter is position-only.
40: (4)                 facecolors : array-like, optional
41: (8)                     Can be used alternatively to *c* to specify colors at the triangle
42: (8)                     faces. This parameter takes precedence over *c*.
43: (4)                 shading : {'flat', 'gouraud'}, default: 'flat'
44: (8)                     If  'flat' and the color values *c* are defined at points, the color
45: (8)                     values used for each triangle are from the mean c of the triangle's
46: (8)                     three points. If *shading* is 'gouraud' then color values must be
47: (8)                     defined at points.
48: (4)                 other_parameters
49: (8)                     All other parameters are the same as for `~.Axes.pcolor`.

(8)                     """
(8)                     Eliminate excessively flat border triangles from the triangulation.
(8)                     Returns a mask *new_mask* which allows to clean the encapsulated
(8)                     triangulation from its border-located flat triangles
(8)                     (according to their :meth:`circle_ratios`).
(8)                     This mask is meant to be subsequently applied to the triangulation
(8)                     using `.Triangulation.set_mask`.
(8)                     *new_mask* is an extension of the initial triangulation mask
(8)                     in the sense that an initially masked triangle will remain masked.
(8)                     The *new_mask* array is computed recursively; at each step flat
(8)                     triangles are removed only if they share a side with the current mesh
(8)                     border. Thus, no new holes in the triangulated domain will be created.
(8)                     Parameters
(8)                     ----------
(8)                     min_circle_ratio : float, default: 0.01
(12)                        Border triangles with incircle/circumcircle radii ratio r/R will
(12)                        be removed if r/R < *min_circle_ratio*.
(8)                     rescale : bool, default: True
(12)                        If True, first, internally rescale (based on `scale_factors`) so
(12)                        that the (unmasked) triangles fit exactly inside a unit square
(12)                        mesh.  This rescaling accounts for the difference of scale which
(12)                        might exist between the 2 axis.
(8)                     Returns
(8)                     -------
(8)                     array of bool
(12)                        Mask to apply to encapsulated triangulation.
(12)                        All the initially masked triangles remain masked in the
(12)                        *new_mask*.
(8)                     Notes
(8)                     -----
(8)                     The rationale behind this function is that a Delaunay
```

```
126: (8)                    triangulation - of an unstructured set of points - sometimes contains
127: (8)                    almost flat triangles at its border, leading to artifacts in plots
128: (8)                    (especially for high-resolution contouring).
