1318: (0)            class fz_store_hash(object):
1319: (4)                r"""
1320: (4)                The store can be seen as a dictionary that maps keys to
1321: (4)                fz_storable values. In order to allow keys of different types to
1322: (4)                be stored, we have a structure full of functions for each key
```

```
1323: (4)               'type'; this fz_store_type pointer is stored with each key, and
1324: (4)               tells the store how to perform certain operations (like taking/
1325: (4)               dropping a reference, comparing two keys, outputting details for
1326: (4)               debugging etc).
1327: (4)               The store uses a hash table internally for speed where possible.
1328: (4)               In order for this to work, we need a mechanism for turning a
1329: (4)               generic 'key' into 'a hashable string'. For this purpose the
1330: (4)               type structure contains a make_hash_key function pointer that
1331: (4)               maps from a void * to a fz_store_hash structure. If
1332: (4)               make_hash_key function returns 0, then the key is determined not
1333: (4)               to be hashable, and the value is not stored in the hash table.
1334: (4)               Some objects can be used both as values within the store, and as
1335: (4)               a component of keys within the store. We refer to these objects
1336: (4)               as "key storable" objects. In this case, we need to take
1337: (4)               additional care to ensure that we do not end up keeping an item
1338: (4)               within the store, purely because its value is referred to by
1339: (4)               another key in the store.
1340: (4)               An example of this are fz_images in PDF files. Each fz_image is
1341: (4)               placed into the    store to enable it to be easily reused. When the
1342: (4)               image is rendered, a pixmap is generated from the image, and the
1343: (4)               pixmap is placed into the store so it can be reused on
1344: (4)               subsequent renders. The image forms part of the key for the
1345: (4)               pixmap.
1346: (4)               When we close the pdf document (and any associated pages/display
1347: (4)               lists etc), we drop the images from the store. This may leave us
1348: (4)               in the position of the images having non-zero reference counts
1349: (4)               purely because they are used as part of the keys for the
1350: (4)               pixmaps.
1351: (4)               We therefore use special reference counting functions to keep
1352: (4)               track of these "key storable" items, and hence store the number
1353: (4)               of references to these items that are used in keys.
1354: (4)               When the number of references to an object == the number of
1355: (4)               references to an object from keys in the store, we know that we
1356: (4)               can remove all the items which have that object as part of the
1357: (4)               key. This is done by running a pass over the store, 'reaping'
1358: (4)               those items.
1359: (4)               Reap passes are slower than we would like as they touch every
1360: (4)               item in the store. We therefore provide a way to 'batch' such
1361: (4)               reap passes together, using fz_defer_reap_start/
1362: (4)               fz_defer_reap_end to bracket a region in which many may be
1363: (4)               triggered.
1364: (4)               """

2026: (4)                Cookie support - simple communication channel between app/library.
2027: (4)                Provide two-way communication between application and library.
2028: (4)                Intended for multi-threaded applications where one thread is
2029: (4)                rendering pages and another thread wants to read progress
2030: (4)                feedback or abort a job that takes a long time to finish. The
2031: (4)                communication is unsynchronized without locking.
2032: (4)                abort: The application should set this field to 0 before
2033: (4)                calling fz_run_page to render a page. At any point when the
2034: (4)                page is being rendered the application my set this field to 1
2035: (4)                which will cause the rendering to finish soon. This field is
2036: (4)                checked periodically when the page is rendered, but exactly
2037: (4)                when is not known, therefore there is no upper bound on
2038: (4)                exactly when the rendering will abort. If the application
2039: (4)                did not provide a set of locks to fz_new_context, it must also
2040: (4)                await the completion of fz_run_page before issuing another
```

```
2041: (4)               call to fz_run_page. Note that once the application has set
2042: (4)               this field to 1 after it called fz_run_page it may not change
2043: (4)               the value again.
2044: (4)               progress: Communicates rendering progress back to the
2045: (4)               application and is read only. Increments as a page is being
2046: (4)               rendered. The value starts out at 0 and is limited to less
2047: (4)               than or equal to progress_max, unless progress_max is -1.
2048: (4)               progress_max: Communicates the known upper bound of rendering
2049: (4)               back to the application and is read only. The maximum value
2050: (4)               that the progress field may take. If there is no known upper
2051: (4)               bound on how long the rendering may take this value is -1 and
2052: (4)               progress is not limited. Note that the value of progress_max
2053: (4)               may change from -1 to a positive value once an upper bound is
2054: (4)               known, so take this into consideration when comparing the
2055: (4)               value of progress to that of progress_max.
2056: (4)               errors: count of errors during current rendering.
2057: (4)               incomplete: Initially should be set to 0. Will be set to
2058: (4)               non-zero if a TRYLATER error is thrown during rendering.

6597: (4)               r"""
6598: (5)                Low-level wrapper for `::fz_getopt_long()`.
```

```
6599: (4)               This function has out-params. Python/C# wrappers look like:
6600: (8)                   `ll_fz_getopt_long(int nargc, const char *ostr, const
::fz_getopt_long_options *longopts)` => `(int, char *nargv)`
6601: (8)                   Simple functions/variables for use in tools.
6602: (8)                   ostr = option string. Comprises single letter options, followed by :
if there
6603: (8)                   is an argument to the option.
6604: (8)                   longopts: NULL (indicating no long options), or a pointer to an array
of
6605: (8)                   longoptions, terminated by an entry with option == NULL.
6606: (8)                   In the event of matching a single char option, this function will
normally
6607: (8)                   return the char. The exception to this is when the option requires an
6608: (8)                   argument and none is supplied; in this case we return ':'.
6609: (8)                   In the event of matching a long option, this function returns 0, with
fz_optlong
6610: (8)                   set to point to the matching option.
6611: (8)                   A long option entry may be followed with : to indicate there is an
argument to the
6612: (8)                   option. If the need for an argument is specified in this way, and no
argument is
6613: (8)                   given, an error will be displayed and argument processing will stop.
If an argument
6614: (8)                   is given, and the long option record contains a non-null flag pointer,
then the code
6615: (8)                   will decode the argument and fill in that flag pointer. Specifically,
6616: (8)                   case-insensitive matches to 'yes', 'no', 'true' and 'false' will cause
a value of 0
6617: (8)                   or 1 as appropriate to be written; failing this the arg will be
interpreted as a
6618: (8)                   decimal integer using atoi.
6619: (8)                   A long option entry may be followed by an list of options (e.g.
myoption=foo|bar|baz)
6620: (8)                   and the option will be passed to fz_opt_from_list. The return value of
that will be
6621: (8)                   placed in fz_optitem. If the return value of that function is -1, then
an error will
6622: (8)                   be displayed and argument processing will stop.
6623: (8)                   In the event of reaching the end of the arg list or '--', this
function returns EOF.
6624: (8)                   In the event of failing to match anything, an error is printed, and we
return '?'.
6625: (8)                   If an argument is expected for the option, then fz_optarg will be
returned pointing
6626: (8)                   at the start of the argument. Examples of supported argument formats:
'-r500', '-r 500',
6627: (8)                   '--resolution 500', '--resolution=500'.
6628: (4)               """

9947: (4)               Low-level wrapper for `::fz_pack_path()`.
9948: (4)               Pack a path into the given block.
9949: (4)               To minimise the size of paths, this function allows them to be
9950: (4)               packed into a buffer with other information. Paths can be used
9951: (4)               interchangeably regardless of how they are packed.
9952: (4)               pack: Pointer to a block of data to pack the path into. Should
9953: (4)               be aligned by the caller to the same alignment as required for
9954: (4)               a fz_path pointer.
9955: (4)               path: The path to pack.
9956: (4)               Returns the number of bytes within the block used. Callers can
9957: (4)               access the packed path data by casting the value of pack on
9958: (4)               entry to be a fz_path *.
9959: (4)               Throws exceptions on failure to allocate.
9960: (4)               Implementation details: Paths can be 'unpacked', 'flat', or
9961: (4)               'open'. Standard paths, as created are 'unpacked'. Paths
9962: (4)               will be packed as 'flat', unless they are too large
9963: (4)               (where large indicates that they exceed some private
9964: (4)               implementation defined limits, currently including having
9965: (4)               more than 256 coordinates or commands).
9966: (4)               Large paths are 'open' packed as a header into the given block,
9967: (4)               plus pointers to other data blocks.
9968: (4)               Users should not have to care about whether paths are 'open'
9969: (4)               or 'flat' packed. Simply pack a path (if required), and then
9970: (4)               forget about the details.

17090: (4)              r"""
17091: (4)              Wrapper class for struct `fz_cookie`. Not copyable or assignable.
17092: (4)              Provide two-way communication between application and library.
17093: (4)              Intended for multi-threaded applications where one thread is
17094: (4)              rendering pages and another thread wants to read progress
17095: (4)              feedback or abort a job that takes a long time to finish. The
```

```
17096: (4)              communication is unsynchronized without locking.
17097: (4)              abort: The application should set this field to 0 before
17098: (4)              calling fz_run_page to render a page. At any point when the
17099: (4)              page is being rendered the application my set this field to 1
17100: (4)              which will cause the rendering to finish soon. This field is
17101: (4)              checked periodically when the page is rendered, but exactly
17102: (4)              when is not known, therefore there is no upper bound on
17103: (4)              exactly when the rendering will abort. If the application
17104: (4)              did not provide a set of locks to fz_new_context, it must also
17105: (4)              await the completion of fz_run_page before issuing another
17106: (4)              call to fz_run_page. Note that once the application has set
17107: (4)              this field to 1 after it called fz_run_page it may not change
17108: (4)              the value again.
17109: (4)              progress: Communicates rendering progress back to the
17110: (4)              application and is read only. Increments as a page is being
17111: (4)              rendered. The value starts out at 0 and is limited to less
17112: (4)              than or equal to progress_max, unless progress_max is -1.
17113: (4)              progress_max: Communicates the known upper bound of rendering
17114: (4)              back to the application and is read only. The maximum value
17115: (4)              that the progress field may take. If there is no known upper
17116: (4)              bound on how long the rendering may take this value is -1 and
17117: (4)              progress is not limited. Note that the value of progress_max
17118: (4)              may change from -1 to a positive value once an upper bound is
17119: (4)              known, so take this into consideration when comparing the
17120: (4)              value of progress to that of progress_max.
17121: (4)              errors: count of errors during current rendering.
17122: (4)              incomplete: Initially should be set to 0. Will be set to
17123: (4)              non-zero if a TRYLATER error is thrown during rendering.

(16)                        is then forwarded onto the target device.
(16)                        target: The target device to receive the OCRd text.
(16)                        ctm: The transform to apply to the mediabox to get the size
for
(16)                        the rendered page image. Also used to calculate the resolution
(16)                        for the page image. In general, this will be the same as the
CTM
(16)                        that you pass to fz_run_page (or fz_run_display_list) to feed
(16)                        this device.
(16)                        mediabox: The mediabox (in points). Combined with the CTM to
get
(16)                        the bounds of the pixmap used internally for the rendered page
(16)                        image.
(16)                        with_list: If with_list is false, then all non-text operations
(16)                        are forwarded instantly to the target device. This results in
```

```
17535: (16)                         the target device seeing all NON-text operations, followed by
17536: (16)                         all the text operations (derived from OCR).
17537: (16)                         If with_list is true, then all the marking operations are
17538: (16)                         collated into a display list which is then replayed to the
17539: (16)                         target device at the end.
17540: (16)                         language: NULL (for "eng"), or a pointer to a string to
describe
17541: (16)                         the languages/scripts that should be used for OCR (e.g.
17542: (16)                         "eng,ara").
17543: (16)                         datadir: NULL (for ""), or a pointer to a path string
otherwise
17544: (16)                         provided to Tesseract in the TESSDATA_PREFIX environment
variable.
17545: (16)                         progress: NULL, or function to be called periodically to
indicate
17546: (16)                         progress. Return 0 to continue, or 1 to cancel. progress_arg
is
17547: (16)                         returned as the void *. The int is a value between 0 and 100
to
17548: (16)                         indicate progress.
17549: (16)                         progress_arg: A void * value to be parrotted back to the
progress
17550: (16)                         function.
17551: (8)                  |

19494: (16)                         Create a scalable image from an SVG document.
19495: (8)                   |
19496: (8)                   *Overload 9:*
19497: (9)                    Constructor using `fz_new_image_of_size()`.
19498: (16)                         Internal function to make a new fz_image structure
19499: (16)                         for a derived class.
19500: (16)                         w,h: Width and height of the created image.
```

```
19501: (16)                         bpc: Bits per component.
19502: (16)                         colorspace: The colorspace (determines the number of
components,
19503: (16)                         and any color conversions required while decoding).
19504: (16)                         xres, yres: The X and Y resolutions respectively.
19505: (16)                         interpolate: 1 if interpolation should be used when decoding
19506: (16)                         this image, 0 otherwise.
19507: (16)                         imagemask: 1 if this is an imagemask (i.e. transparent), 0
19508: (16)                         otherwise.
19509: (16)                         decode: NULL, or a pointer to to a decode array. The default
19510: (16)                         decode array is [0 1] (repeated n times, for n color
components).
19511: (16)                         colorkey: NULL, or a pointer to a colorkey array. The default
19512: (16)                         colorkey array is [0 255] (repeated n times, for n color
19513: (16)                         components).
19514: (16)                         mask: NULL, or another image to use as a mask for this one.
19515: (16)                         A new reference is taken to this image. Supplying a masked
19516: (16)                         image as a mask to another image is illegal!
19517: (16)                         size: The size of the required allocated structure (the size
of
19518: (16)                         the derived structure).
19519: (16)                         get: The function to be called to obtain a decoded pixmap.
19520: (16)                         get_size: The function to be called to return the storage size
19521: (16)                         used by this image.
19522: (16)                         drop: The function to be called to dispose of this image once
19523: (16)                         the last reference is dropped.
19524: (16)                         Returns a pointer to an allocated structure of the required
size,
19525: (16)                         with the first sizeof(fz_image) bytes initialised as
appropriate
19526: (16)                         given the supplied parameters, and the other bytes set to
zero.

23945: (0)          class FzStoreHash(object):
23946: (4)              r"""
23947: (4)              Wrapper class for struct `fz_store_hash`. Not copyable or assignable.
23948: (4)              The store can be seen as a dictionary that maps keys to
23949: (4)              fz_storable values. In order to allow keys of different types to
23950: (4)              be stored, we have a structure full of functions for each key
23951: (4)              'type'; this fz_store_type pointer is stored with each key, and
23952: (4)              tells the store how to perform certain operations (like taking/
23953: (4)              dropping a reference, comparing two keys, outputting details for
23954: (4)              debugging etc).
23955: (4)              The store uses a hash table internally for speed where possible.
23956: (4)              In order for this to work, we need a mechanism for turning a
23957: (4)              generic 'key' into 'a hashable string'. For this purpose the
23958: (4)              type structure contains a make_hash_key function pointer that
23959: (4)              maps from a void * to a fz_store_hash structure. If
23960: (4)              make_hash_key function returns 0, then the key is determined not
23961: (4)              to be hashable, and the value is not stored in the hash table.
23962: (4)              Some objects can be used both as values within the store, and as
23963: (4)              a component of keys within the store. We refer to these objects
23964: (4)              as "key storable" objects. In this case, we need to take
23965: (4)              additional care to ensure that we do not end up keeping an item
23966: (4)              within the store, purely because its value is referred to by
23967: (4)              another key in the store.
23968: (4)              An example of this are fz_images in PDF files. Each fz_image is
23969: (4)              placed into the    store to enable it to be easily reused. When the
23970: (4)              image is rendered, a pixmap is generated from the image, and the
23971: (4)              pixmap is placed into the store so it can be reused on
23972: (4)              subsequent renders. The image forms part of the key for the
23973: (4)              pixmap.
23974: (4)              When we close the pdf document (and any associated pages/display
23975: (4)              lists etc), we drop the images from the store. This may leave us
23976: (4)              in the position of the images having non-zero reference counts
23977: (4)              purely because they are used as part of the keys for the
23978: (4)              pixmaps.
23979: (4)              We therefore use special reference counting functions to keep
23980: (4)              track of these "key storable" items, and hence store the number
23981: (4)              of references to these items that are used in keys.
23982: (4)              When the number of references to an object == the number of
23983: (4)              references to an object from keys in the store, we know that we
23984: (4)              can remove all the items which have that object as part of the
23985: (4)              key. This is done by running a pass over the store, 'reaping'
23986: (4)              those items.
23987: (4)              Reap passes are slower than we would like as they touch every
23988: (4)              item in the store. We therefore provide a way to 'batch' such
23989: (4)              reap passes together, using fz_defer_reap_start/
23990: (4)              fz_defer_reap_end to bracket a region in which many may be
23991: (4)              triggered.
