31850: (4)              Class-aware wrapper for `::fz_getopt_long()`.
31851: (4)              This function has out-params. Python/C# wrappers look like:
31852: (8)                  `fz_getopt_long(int nargc, const char *ostr, const
::fz_getopt_long_options *longopts)` => `(int, char *nargv)`
31853: (8)                  Simple functions/variables for use in tools.
31854: (8)                  ostr = option string. Comprises single letter options, followed by :
if there
31855: (8)                  is an argument to the option.
31856: (8)                  longopts: NULL (indicating no long options), or a pointer to an array
of
31857: (8)                  longoptions, terminated by an entry with option == NULL.
31858: (8)                  In the event of matching a single char option, this function will
normally
31859: (8)                  return the char. The exception to this is when the option requires an
31860: (8)                  argument and none is supplied; in this case we return ':'.
31861: (8)                  In the event of matching a long option, this function returns 0, with
fz_optlong
31862: (8)                  set to point to the matching option.
31863: (8)                  A long option entry may be followed with : to indicate there is an
argument to the
31864: (8)                  option. If the need for an argument is specified in this way, and no
argument is
31865: (8)                  given, an error will be displayed and argument processing will stop.
If an argument
31866: (8)                  is given, and the long option record contains a non-null flag pointer,
then the code
31867: (8)                  will decode the argument and fill in that flag pointer. Specifically,
31868: (8)                  case-insensitive matches to 'yes', 'no', 'true' and 'false' will cause
a value of 0
31869: (8)                  or 1 as appropriate to be written; failing this the arg will be
interpreted as a
31870: (8)                  decimal integer using atoi.
31871: (8)                  A long option entry may be followed by an list of options (e.g.
myoption=foo|bar|baz)
31872: (8)                  and the option will be passed to fz_opt_from_list. The return value of
that will be
31873: (8)                  placed in fz_optitem. If the return value of that function is -1, then
an error will
31874: (8)                  be displayed and argument processing will stop.
31875: (8)                  In the event of reaching the end of the arg list or '--', this
function returns EOF.
31876: (8)                  In the event of failing to match anything, an error is printed, and we
return '?'.
31877: (8)                  If an argument is expected for the option, then fz_optarg will be
returned pointing
31878: (8)                  at the start of the argument. Examples of supported argument formats:
'-r500', '-r 500',
31879: (8)                  '--resolution 500', '--resolution=500'.
31880: (4)              """

34523: (8)                 Pack a path into the given block.
34524: (8)                 To minimise the size of paths, this function allows them to be
34525: (8)                 packed into a buffer with other information. Paths can be used
34526: (8)                 interchangeably regardless of how they are packed.
34527: (8)                 pack: Pointer to a block of data to pack the path into. Should
34528: (8)                 be aligned by the caller to the same alignment as required for
34529: (8)                 a fz_path pointer.
34530: (8)                 path: The path to pack.
34531: (8)                 Returns the number of bytes within the block used. Callers can
34532: (8)                 access the packed path data by casting the value of pack on
34533: (8)                 entry to be a fz_path *.
34534: (8)                 Throws exceptions on failure to allocate.
34535: (8)                 Implementation details: Paths can be 'unpacked', 'flat', or
34536: (8)                 'open'. Standard paths, as created are 'unpacked'. Paths
34537: (8)                 will be packed as 'flat', unless they are too large
34538: (8)                 (where large indicates that they exceed some private
34539: (8)                 implementation defined limits, currently including having
34540: (8)                 more than 256 coordinates or commands).
34541: (8)                 Large paths are 'open' packed as a header into the given block,
34542: (8)                 plus pointers to other data blocks.
34543: (8)                 Users should not have to care about whether paths are 'open'
34544: (8)                 or 'flat' packed. Simply pack a path (if required), and then
34545: (8)                 forget about the details.
34546: (4)             """

41238: (4)              Shows an exception and/or backtrace.
41239: (4)              Alternative to `traceback.*` functions that print/return information about
41240: (4)              exceptions and backtraces, such as:
41241: (8)                  * `traceback.format_exc()`
41242: (8)                  * `traceback.format_exception()`
41243: (8)                  * `traceback.print_exc()`
41244: (8)                  * `traceback.print_exception()`
41245: (4)              Install as system default with:
41246: (8)                  `sys.excepthook = lambda type_, exception, traceback:
jlib.exception_info( exception)`
41247: (4)              Returns `None`, or the generated text if `file` is 'return'.
41248: (4)              Args:
41249: (8)                  exception_or_traceback:
41250: (12)                     `None`, a `BaseException`, a `types.TracebackType` (typically from
41251: (12)                     an exception's `.__traceback__` member) or an `inspect.FrameInfo`.
41252: (12)                     If `None` we use current exception from `sys.exc_info()` if set,
41253: (12)                     otherwise the current backtrace from `inspect.stack()`.
41254: (8)                  limit:
41255: (12)                     As in `traceback.*` functions: `None` to show all frames, positive
41256: (12)                     to show last `limit` frames, negative to exclude outermost `-
limit`
41257: (12)                     frames. Zero to not show any backtraces.
41258: (8)                  file:
41259: (12)                     As in `traceback.*` functions: file-like object to which we write
41260: (12)                     output, or `sys.stderr` if `None`. Special value 'return' makes us
41261: (12)                     return our output as a string.
41262: (8)                  chain:
41263: (12)                     As in `traceback.*` functions: if true (the default) we show
41264: (12)                     chained exceptions as described in PEP-3134. Special value
```

```
(12)                    'because' reverses the usual ordering, showing higher-level
(12)                    exceptions first and joining with 'Because:' text.
(8)                 outer:
(12)                    If true (the default) we also show an exception's outer frames
(12)                    above the `catch` block (see next section for details). We
(12)                    use `outer=false` internally for chained exceptions to avoid
(12)                    duplication.
(8)                 show_exception_type:
(12)                    Controls whether exception text is prefixed by
(12)                    `f'{type(exception)}: '`. If callable we only include this prefix
(12)                    if `show_exception_type(exception)` is true. Otherwise if true
(the
(12)                    default) we include the prefix for all exceptions (this mimcs the
(12)                    behaviour of `traceback.*` functions). Otherwise we exclude the
(12)                    prefix for all exceptions.
(8)                 _filelinefn:
(12)                    Internal only; makes us omit file:line: information to allow
simple
(12)                    doctest comparison with expected output.
(4)             Differences from `traceback.*` functions:
(8)                 Frames are displayed as one line in the form::
(12)                    <file>:<line>:<function>: <text>
(8)                 Filenames are displayed as relative to the current directory if
(8)                 applicable.
(8)                 Inclusion of outer frames:
(12)                    Unlike `traceback.*` functions, stack traces for exceptions
include
(12)                    outer stack frames above the point at which an exception was
caught
(12)                    - i.e. frames from the top-level <module> or thread creation to
the
(12)                    catch block. [Search for 'sys.exc_info backtrace incomplete' for
(12)                    more details.]
(12)                    We separate the two parts of the backtrace using a marker line
(12)                    '^except raise:' where '^except' points upwards to the frame that
(12)                    caught the exception and 'raise:' refers downwards to the frame
(12)                    that raised the exception.
(12)                    So the backtrace for an exception looks like this::
(16)                        <file>:<line>:<fn>: <text>  [in root module.]
(16)                        ...                         [... other frames]
(16)                        <file>:<line>:<fn>: <text>  [in except: block where exception
was caught.]
(16)                        ^except raise:              [marker line]
(16)                        <file>:<line>:<fn>: <text>  [in try: block.]
(16)                        ...                         [... other frames]
(16)                        <file>:<line>:<fn>: <text>  [where the exception was raised.]
(4)             Examples:
(8)                 In these examples we use `file=sys.stdout` so we can check the output
(8)                 with `doctest`, and set `_filelinefn=0` so that the output can be
(8)                 matched easily. We also use `+ELLIPSIS` and `...` to match arbitrary
(8)                 outer frames from the doctest code itself.
(8)                 Basic handling of an exception:
(12)                    >>> def c():
(12)                    ...     raise Exception( 'c() failed')
(12)                    >>> def b():
(12)                    ...     try:
(12)                    ...         c()
(12)                    ...     except Exception as e:
(12)                    ...         exception_info( e, file=sys.stdout, _filelinefn=0)
(12)                    >>> def a():
(12)                    ...     b()
(12)                    >>> a() # doctest: +REPORT_UDIFF +ELLIPSIS
(12)                    Traceback (most recent call last):
(16)                        ...
(16)                        a(): b()
(16)                        b(): exception_info( e, file=sys.stdout, _filelinefn=0)
(16)                        ^except raise:
(16)                        b(): c()
(16)                        c(): raise Exception( 'c() failed')
```

```
    Exception: c() failed
Handling of chained exceptions:
    >>> def e():
    ...     raise Exception( 'e(): deliberate error')
    >>> def d():
    ...     e()
    >>> def c():
    ...     try:
    ...         d()
    ...     except Exception as e:
    ...         raise Exception( 'c: d() failed') from e
    >>> def b():
    ...     try:
    ...         c()
    ...     except Exception as e:
    ...         exception_info( file=sys.stdout, chain=g_chain, _filelinefn=0)
    >>> def a():
    ...     b()
    With `chain=True` (the default), we output low-level exceptions
    first, matching the behaviour of `traceback.*` functions:
        >>> g_chain = True
        >>> a() # doctest: +REPORT_UDIFF +ELLIPSIS
        Traceback (most recent call last):
            c(): d()
            d(): e()
            e(): raise Exception( 'e(): deliberate error')
        Exception: e(): deliberate error
        <BLANKLINE>
        The above exception was the direct cause of the following exception:

        Traceback (most recent call last):
            ...
            <module>(): a() # doctest: +REPORT_UDIFF +ELLIPSIS
            a(): b()
            b(): exception_info( file=sys.stdout, chain=g_chain, _filelinefn=0)

            ^except raise:
            b(): c()
            c(): raise Exception( 'c: d() failed') from e
        Exception: c: d() failed
    With `chain='because'`, we output high-level exceptions first:
        >>> g_chain = 'because'
        >>> a() # doctest: +REPORT_UDIFF +ELLIPSIS
        Traceback (most recent call last):
            ...
            <module>(): a() # doctest: +REPORT_UDIFF +ELLIPSIS
            a(): b()
            b(): exception_info( file=sys.stdout, chain=g_chain, _filelinefn=0)

            ^except raise:
            b(): c()
            c(): raise Exception( 'c: d() failed') from e
        Exception: c: d() failed
        <BLANKLINE>
        Because:
        Traceback (most recent call last):
            c(): d()
            d(): e()
            e(): raise Exception( 'e(): deliberate error')
        Exception: e(): deliberate error
Show current backtrace by passing `exception_or_traceback=None`:
    >>> def c():
    ...     exception_info( None, file=sys.stdout, _filelinefn=0)
    >>> def b():
    ...     return c()
    >>> def a():
    ...     return b()
    >>> a() # doctest: +REPORT_UDIFF +ELLIPSIS
```

```
41393: (12)                     Traceback (most recent call last):

40: (0)             ---------------------------------------------------------------------
41: (0)             Also see here: https://github.com/jsvine/pdfplumber/blob/stable/LICENSE.txt
42: (0)             ---------------------------------------------------------------------
43: (0)             The porting mainly pertains to files "table.py" and relevant parts of
44: (0)             "utils/text.py" within pdfplumber's repository on Github.
45: (0)             With respect to "text.py", we have removed functions or features that are not
46: (0)             used by table processing. Examples are:
47: (0)             * the text search function
48: (0)             * simple text extraction
49: (0)             * text extraction by lines
50: (0)             Original pdfplumber code does neither detect, nor identify table headers.
51: (0)             This PyMuPDF port adds respective code to the 'Table' class as method
'_get_header'.
52: (0)             This is implemented as new class TableHeader with the properties:
53: (0)             * bbox: A tuple for the header's bbox
54: (0)             * cells: A tuple for each bbox of a column header
55: (0)             * names: A list of strings with column header text
56: (0)             * external: A bool indicating whether the header is outside the table cells.
57: (0)             """

178: (8)                    Given a list of (word, chars) tuples (i.e., a WordMap), return a list
of
179: (8)                    (char-text, char) tuples (i.e., a TextMap) that can be used to mimic
the
180: (8)                    structural layout of the text on the page(s), using the following
approach:
181: (8)                    - Sort the words by (doctop, x0) if not already sorted.
182: (8)                    - Calculate the initial doctop for the starting page.
183: (8)                    - Cluster the words by doctop (taking `y_tolerance` into account), and
184: (10)                     iterate through them.
185: (8)                    - For each cluster, calculate the distance between that doctop and the
186: (10)                     initial doctop, in points, minus `y_shift`. Divide that distance by
187: (10)                     `y_density` to calculate the minimum number of newlines that should
come
188: (10)                     before this cluster. Append that number of newlines *minus* the
number of
189: (10)                     newlines already appended, with a minimum of one.
190: (8)                    - Then for each cluster, iterate through each word in it. Divide each
191: (10)                     word's x0, minus `x_shift`, by `x_density` to calculate the minimum
192: (10)                     number of characters that should come before this cluster.  Append
that
193: (10)                     number of spaces *minus* the number of characters and spaces already
194: (10)                     appended, with a minimum of one. Then append the word's text.
195: (8)                    - At the termination of each line, add more spaces if necessary to
196: (10)                     mimic `layout_width`.
197: (8)                    - Finally, add newlines to the end if necessary to mimic to
198: (10)                     `layout_height`.
199: (8)                    Note: This approach currently works best for horizontal, left-to-right
200: (8)                    text, but will display all words regardless of orientation. There is
room
201: (8)                    for improvement in better supporting right-to-left text, as well as
202: (8)                    vertical text.

(8)                 curr_char,
(4)             ) -> bool:
(8)                 """This method takes several factors into account to determine if
(8)                 `curr_char` represents the beginning of a new word:
(8)                 - Whether the text is "upright" (i.e., non-rotated)
(8)                 - Whether the user has specified that horizontal text runs
(10)                  left-to-right (default) or right-to-left, as represented by
(10)                  self.horizontal_ltr
(8)                 - Whether the user has specified that vertical text the text runs
(10)                  top-to-bottom (default) or bottom-to-top, as represented by
(10)                  self.vertical_ttb
(8)                 - The x0, top, x1, and bottom attributes of prev_char and
(10)                  curr_char
(8)                 - The self.x_tolerance and self.y_tolerance settings. Note: In
(10)                  this case, x/y refer to those directions for non-rotated text.
(10)                  For vertical text, they are flipped. A more accurate terminology
(10)                  might be "*intra*line character distance tolerance" and
(10)                  "*inter*line character distance tolerance"
(8)                 An important note: The *intra*line distance is measured from the
(8)                 *end* of the previous character to the *beginning* of the current
(8)                 character, while the *inter*line distance is measured from the
(8)                 *top* of the previous character to the *top* of the next
(8)                 character. The reasons for this are partly repository-historical,
(8)                 and partly logical, as successive text lines' bounding boxes often
(8)                 overlap slightly (and we don't want that overlap to be interpreted
(8)                 as the two lines being the same line).
(8)                 The upright-ness of the character determines the attributes to
(8)                 compare, while horizontal_ltr/vertical_ttb determine the direction
(8)                 of the comparison.
(8)                 """
