194: (7)                   all edges. Usual values could be `1` or `True`. If `edge_data` is
195: (7)                   `None` (the default), the edgedata in `G` is used, resulting in a
196: (7)                   dict-of-dict-of-dicts. If `G` is a MultiGraph, the result will be a
197: (7)                   dict-of-dict-of-dict-of-dicts. See Notes for an approach to customize
198: (7)                   handling edge data. `edge_data` should *not* be a container.
199: (4)                Returns
200: (4)                -------
201: (4)                dod : dict
202: (7)                   A nested dictionary representation of `G`. Note that the level of
203: (7)                   nesting depends on the type of `G` and the value of `edge_data`
204: (7)                   (see Examples).
205: (4)                See Also
206: (4)                --------
207: (4)                from_dict_of_dicts, to_dict_of_lists
208: (4)                Notes
209: (4)                -----
210: (4)                For a more custom approach to handling edge data, try::
211: (8)                    dod = {
212: (12)                       n: {nbr: custom(n, nbr, dd) for nbr, dd in nbrdict.items()}
213: (12)                       for n, nbrdict in G.adj.items()
214: (8)                    }
215: (4)                where `custom` returns the desired edge data for each edge between `n` and
216: (4)                `nbr`, given existing edge data `dd`.
217: (4)                Examples
218: (4)                --------
219: (4)                >>> G = nx.path_graph(3)
220: (4)                >>> nx.to_dict_of_dicts(G)
221: (4)                {0: {1: {}}, 1: {0: {}, 2: {}}, 2: {1: {}}}
222: (4)                Edge data is preserved by default (``edge_data=None``), resulting
223: (4)                in dict-of-dict-of-dicts where the innermost dictionary contains the
224: (4)                edge data:
225: (4)                >>> G = nx.Graph()
```

```
226: (4)                >>> G.add_edges_from(
227: (4)                ...     [
228: (4)                ...         (0, 1, {"weight": 1.0}),
229: (4)                ...         (1, 2, {"weight": 2.0}),
230: (4)                ...         (2, 0, {"weight": 1.0}),
231: (4)                ...     ]
232: (4)                ... )
233: (4)                >>> d = nx.to_dict_of_dicts(G)
234: (4)                >>> d  # doctest: +SKIP
235: (4)                {0: {1: {'weight': 1.0}, 2: {'weight': 1.0}},
236: (5)                 1: {0: {'weight': 1.0}, 2: {'weight': 2.0}},
237: (5)                 2: {1: {'weight': 2.0}, 0: {'weight': 1.0}}}
238: (4)                >>> d[1][2]["weight"]
239: (4)                2.0
240: (4)                If `edge_data` is not `None`, edge data in the original graph (if any) is
241: (4)                replaced:
242: (4)                >>> d = nx.to_dict_of_dicts(G, edge_data=1)
243: (4)                >>> d
244: (4)                {0: {1: 1, 2: 1}, 1: {0: 1, 2: 1}, 2: {1: 1, 0: 1}}
245: (4)                >>> d[1][2]
246: (4)                1
247: (4)                This also applies to MultiGraphs: edge data is preserved by default:
248: (4)                >>> G = nx.MultiGraph()
249: (4)                >>> G.add_edge(0, 1, key="a", weight=1.0)
250: (4)                'a'
251: (4)                >>> G.add_edge(0, 1, key="b", weight=5.0)
252: (4)                'b'
253: (4)                >>> d = nx.to_dict_of_dicts(G)
254: (4)                >>> d  # doctest: +SKIP
255: (4)                {0: {1: {'a': {'weight': 1.0}, 'b': {'weight': 5.0}}},
256: (5)                 1: {0: {'a': {'weight': 1.0}, 'b': {'weight': 5.0}}}}
257: (4)                >>> d[0][1]["b"]["weight"]
258: (4)                5.0
259: (4)                But multi edge data is lost if `edge_data` is not `None`:
260: (4)                >>> d = nx.to_dict_of_dicts(G, edge_data=10)
261: (4)                >>> d
262: (4)                {0: {1: 10}, 1: {0: 10}}
263: (4)                """

File 4 - convert_matrix.py:

```
1: (0)              """Functions to convert NetworkX graphs to and from common data containers
2: (0)              like numpy arrays, scipy sparse arrays, and pandas DataFrames.
3: (0)              The preferred way of converting data to a NetworkX graph is through the
4: (0)              graph constructor.  The constructor calls the
`~networkx.convert.to_networkx_graph`
5: (0)              function which attempts to guess the input type and convert it automatically.
6: (0)              Examples
7: (0)              --------
8: (0)              Create a 10 node random graph from a numpy array
9: (0)              >>> import numpy as np
10: (0)             >>> rng = np.random.default_rng()
11: (0)             >>> a = rng.integers(low=0, high=2, size=(10, 10))
12: (0)             >>> DG = nx.from_numpy_array(a, create_using=nx.DiGraph)
13: (0)             or equivalently:
14: (0)             >>> DG = nx.DiGraph(a)
15: (0)             which calls `from_numpy_array` internally based on the type of ``a``.
16: (0)             See Also
17: (0)             --------
18: (0)             nx_agraph, nx_pydot

45: (4)                 Parameters
46: (4)                 ----------
47: (4)                 G : graph
48: (8)                     The NetworkX graph used to construct the Pandas DataFrame.
49: (4)                 nodelist : list, optional
50: (7)                    The rows and columns are ordered according to the nodes in `nodelist`.
```

```
   If `nodelist` is None, then the ordering is produced by G.nodes().
multigraph_weight : {sum, min, max}, optional
    An operator that determines how weights in multigraphs are handled.
    The default is to sum the weights of the multiple edges.
weight : string or None, optional
    The edge attribute that holds the numerical value used for
    the edge weight.  If an edge does not have that attribute, then the
    value 1 is used instead.
nonedge : float, optional
    The matrix values corresponding to nonedges are typically set to zero.
    However, this could be undesirable if there are matrix values
    corresponding to actual edges that also have the value zero. If so,
    one might prefer nonedges to have some other value, such as nan.
Returns
-------
df : Pandas DataFrame
   Graph adjacency matrix
Notes
-----
For directed graphs, entry i,j corresponds to an edge from i to j.
The DataFrame entries are assigned to the weight edge attribute. When
an edge does not have a weight attribute, the value of the entry is set to
the number 1.  For multiple (parallel) edges, the values of the entries
are determined by the 'multigraph_weight' parameter.  The default is to
sum the weight attributes for each of the parallel edges.
When `nodelist` does not contain every node in `G`, the matrix is built
from the subgraph of `G` that is induced by the nodes in `nodelist`.
The convention used for self-loop edges in graphs is to assign the
diagonal matrix entry value to the weight attribute of the edge
(or the number 1 if the edge has no weight attribute).  If the
alternate convention of doubling the edge weight is desired the
resulting Pandas DataFrame can be modified as follows::
    >>> import pandas as pd
    >>> G = nx.Graph([(1, 1), (2, 2)])
    >>> df = nx.to_pandas_adjacency(G)
    >>> df
         1    2
    1  1.0  0.0
    2  0.0  1.0
    >>> diag_idx = list(range(len(df)))
    >>> df.iloc[diag_idx, diag_idx] *= 2
    >>> df
         1    2
    1  2.0  0.0
    2  0.0  2.0
Examples
--------
>>> G = nx.MultiDiGraph()
>>> G.add_edge(0, 1, weight=2)
0
>>> G.add_edge(1, 0)
0
>>> G.add_edge(2, 2, weight=3)
0
>>> G.add_edge(2, 2)
1
>>> nx.to_pandas_adjacency(G, nodelist=[0, 1, 2], dtype=int)
   0  1  2
0  0  2  0
1  1  0  0
2  0  0  4

412: (8)                    the edge weight.  If None then all edge weights are 1.
413: (4)                format : str in {'bsr', 'csr', 'csc', 'coo', 'lil', 'dia', 'dok'}
414: (8)                    The type of the matrix to be returned (default 'csr').  For
415: (8)                    some algorithms different implementations of sparse matrices
416: (8)                    can perform better.  See [1]_ for details.
417: (4)                Returns
418: (4)                -------
419: (4)                A : SciPy sparse array
420: (7)                   Graph adjacency matrix.
421: (4)                Notes
422: (4)                -----
423: (4)                For directed graphs, matrix entry i,j corresponds to an edge from i to j.
424: (4)                The matrix entries are populated using the edge attribute held in
425: (4)                parameter weight. When an edge does not have that attribute, the
426: (4)                value of the entry is 1.
427: (4)                For multiple edges the matrix values are the sums of the edge weights.
428: (4)                When `nodelist` does not contain every node in `G`, the adjacency matrix
429: (4)                is built from the subgraph of `G` that is induced by the nodes in
430: (4)                `nodelist`.
431: (4)                The convention used for self-loop edges in graphs is to assign the
432: (4)                diagonal matrix entry value to the weight attribute of the edge
433: (4)                (or the number 1 if the edge has no weight attribute).  If the
434: (4)                alternate convention of doubling the edge weight is desired the
435: (4)                resulting SciPy sparse array can be modified as follows:
436: (4)                >>> G = nx.Graph([(1, 1)])
437: (4)                >>> A = nx.to_scipy_sparse_array(G)

(4)                 array.
(4)                 Parameters
(4)                 ----------
(4)                 A: scipy.sparse array
(6)                   An adjacency matrix representation of a graph
(4)                 parallel_edges : Boolean
(6)                   If this is True, `create_using` is a multigraph, and `A` is an
(6)                   integer matrix, then entry *(i, j)* in the matrix is interpreted as the
(6)                   number of parallel edges joining vertices *i* and *j* in the graph.
(6)                   If it is False, then the entries in the matrix are interpreted as
(6)                   the weight of a single edge joining the vertices.
(4)                 create_using : NetworkX graph constructor, optional (default=nx.Graph)
(7)                    Graph type to create. If graph instance, then cleared before populated.
(4)                 edge_attribute: string
(7)                    Name of edge attribute to store matrix numeric value. The data will
(7)                    have the same type as the matrix entry (int, float, (real,imag)).
(4)                 Notes
(4)                 -----
(4)                 For directed graphs, explicitly mention create_using=nx.DiGraph,
(4)                 and entry i,j of A corresponds to an edge from i to j.
(4)                 If `create_using` is :class:`networkx.MultiGraph` or
(4)                 :class:`networkx.MultiDiGraph`, `parallel_edges` is True, and the
(4)                 entries of `A` are of type :class:`int`, then this function returns a
(4)                 multigraph (constructed from `create_using`) with parallel edges.
(4)                 In this case, `edge_attribute` will be ignored.
(4)                 If `create_using` indicates an undirected multigraph, then only the edges
(4)                 indicated by the upper triangle of the matrix `A` will be added to the
(4)                 graph.
(4)                 Examples
(4)                 --------
(4)                 >>> import scipy as sp
(4)                 >>> A = sp.sparse.eye(2, 2, 1)
(4)                 >>> G = nx.from_scipy_sparse_array(A)
```

```
586: (4)                If `create_using` indicates a multigraph and the matrix has only integer
587: (4)                entries and `parallel_edges` is False, then the entries will be treated
588: (4)                as weights for edges joining the nodes (without creating parallel edges):
589: (4)                >>> A = sp.sparse.csr_array([[1, 1], [1, 2]])
590: (4)                >>> G = nx.from_scipy_sparse_array(A, create_using=nx.MultiGraph)
591: (4)                >>> G[1][1]
592: (4)                AtlasView({0: {'weight': 2}})
593: (4)                If `create_using` indicates a multigraph and the matrix has only integer
594: (4)                entries and `parallel_edges` is True, then the entries will be treated
595: (4)                as the number of parallel edges joining those two vertices:
596: (4)                >>> A = sp.sparse.csr_array([[1, 1], [1, 2]])
597: (4)                >>> G = nx.from_scipy_sparse_array(A, parallel_edges=True,
create_using=nx.MultiGraph)
598: (4)                >>> G[1][1]
599: (4)                AtlasView({0: {'weight': 1}, 1: {'weight': 1}})
600: (4)                """
601: (4)                G = nx.empty_graph(0, create_using)
602: (4)                n, m = A.shape
603: (4)                if n != m:

606: (4)                triples = _generate_weighted_edges(A)
607: (4)                if A.dtype.kind in ("i", "u") and G.is_multigraph() and parallel_edges:
608: (8)                    chain = itertools.chain.from_iterable
609: (8)                    triples = chain(((u, v, 1) for d in range(w)) for (u, v, w) in
triples)
610: (4)                if G.is_multigraph() and not G.is_directed():
611: (8)                    triples = ((u, v, d) for u, v, d in triples if u <= v)
612: (4)                G.add_weighted_edges_from(triples, weight=edge_attribute)
613: (4)                return G
614: (0)            @nx._dispatchable(edge_attrs="weight")  # edge attrs may also be obtained from
`dtype`
615: (0)            def to_numpy_array(
616: (4)                G,
617: (4)                nodelist=None,
618: (4)                dtype=None,
619: (4)                order=None,
620: (4)                multigraph_weight=sum,
621: (4)                weight="weight",
622: (4)                nonedge=0.0,
623: (0)            ):
624: (4)                """Returns the graph adjacency matrix as a NumPy array.
625: (4)                Parameters
626: (4)                ----------
627: (4)                G : graph
628: (8)                    The NetworkX graph used to construct the NumPy array.
629: (4)                nodelist : list, optional
630: (8)                    The rows and columns are ordered according to the nodes in `nodelist`.
631: (8)                    If `nodelist` is ``None``, then the ordering is produced by
``G.nodes()``.
632: (4)                dtype : NumPy data type, optional
633: (8)                    A NumPy data type used to initialize the array. If None, then the
NumPy
634: (8)                    default is used. The dtype can be structured if `weight=None`, in
which
635: (8)                    case the dtype field names are used to look up edge attributes. The
636: (8)                    result is a structured array where each named field in the dtype
637: (8)                    corresponds to the adjacency for that edge attribute. See examples for
638: (8)                    details.
639: (4)                order : {'C', 'F'}, optional
640: (8)                    Whether to store multidimensional data in C- or Fortran-contiguous
641: (8)                    (row- or column-wise) order in memory. If None, then the NumPy default
642: (8)                    is used.
643: (4)                multigraph_weight : callable, optional
644: (8)                    An function that determines how weights in multigraphs are handled.
645: (8)                    The function should accept a sequence of weights and return a single
646: (8)                    value. The default is to sum the weights of the multiple edges.
647: (4)                weight : string or None optional (default = 'weight')
```

```
(8)                 The edge attribute that holds the numerical value used for
(8)                 the edge weight. If an edge does not have that attribute, then the
(8)                 value 1 is used instead. `weight` must be ``None`` if a structured
(8)                 dtype is used.
(4)             nonedge : array_like (default = 0.0)
(8)                 The value used to represent non-edges in the adjacency matrix.
(8)                 The array values corresponding to nonedges are typically set to zero.
(8)                 However, this could be undesirable if there are array values
(8)                 corresponding to actual edges that also have the value zero. If so,
(8)                 one might prefer nonedges to have some other value, such as ``nan``.
(4)             Returns
(4)             -------
(4)             A : NumPy ndarray
(8)                 Graph adjacency matrix
(4)             Raises
(4)             ------
(4)             NetworkXError
(8)                 If `dtype` is a structured dtype and `G` is a multigraph
(4)             ValueError
(8)                 If `dtype` is a structured dtype and `weight` is not `None`
(4)             See Also
(4)             --------
(4)             from_numpy_array
(4)             Notes
(4)             -----
(4)             For directed graphs, entry ``i, j`` corresponds to an edge from ``i`` to
``j``.
(4)             Entries in the adjacency matrix are given by the `weight` edge attribute.
(4)             When an edge does not have a weight attribute, the value of the entry is
(4)             set to the number 1.  For multiple (parallel) edges, the values of the
(4)             entries are determined by the `multigraph_weight` parameter. The default
is
(4)             to sum the weight attributes for each of the parallel edges.
(4)             When `nodelist` does not contain every node in `G`, the adjacency matrix
is
(4)             built from the subgraph of `G` that is induced by the nodes in `nodelist`.
(4)             The convention used for self-loop edges in graphs is to assign the
(4)             diagonal array entry value to the weight attribute of the edge
(4)             (or the number 1 if the edge has no weight attribute). If the
(4)             alternate convention of doubling the edge weight is desired the
(4)             resulting NumPy array can be modified as follows:
(4)             >>> import numpy as np
(4)             >>> G = nx.Graph([(1, 1)])
(4)             >>> A = nx.to_numpy_array(G)
(4)             >>> A
(4)             array([[1.]])
(4)             >>> A[np.diag_indices_from(A)] *= 2
(4)             >>> A
(4)             array([[2.]])
(4)             Examples
(4)             --------
(4)             >>> G = nx.MultiDiGraph()
(4)             >>> G.add_edge(0, 1, weight=2)
(4)             0
(4)             >>> G.add_edge(1, 0)
(4)             0
(4)             >>> G.add_edge(2, 2, weight=3)
(4)             0
(4)             >>> G.add_edge(2, 2)
(4)             1
(4)             >>> nx.to_numpy_array(G, nodelist=[0, 1, 2])
(4)             array([[0., 2., 0.],
(11)                   [1., 0., 0.],
(11)                   [0., 0., 4.]])
(4)             When `nodelist` argument is used, nodes of `G` which do not appear in the
`nodelist`
(4)             and their edges are not included in the adjacency matrix. Here is an
example:
(4)             >>> G = nx.Graph()
```

```
(4)                 >>> G.add_edge(3, 1)
(4)                 >>> G.add_edge(2, 0)
(4)                 >>> G.add_edge(2, 1)
(4)                 >>> G.add_edge(3, 0)
(4)                 >>> nx.to_numpy_array(G, nodelist=[1, 2, 3])
(4)                 array([[0., 1., 1.],
(11)                       [1., 0., 0.],
(11)                       [1., 0., 0.]])
(4)                 This function can also be used to create adjacency matrices for multiple
(4)                 edge attributes with structured dtypes:
(4)                 >>> G = nx.Graph()
(4)                 >>> G.add_edge(0, 1, weight=10)
(4)                 >>> G.add_edge(1, 2, cost=5)
(4)                 >>> G.add_edge(2, 3, weight=3, cost=-4.0)
(4)                 >>> dtype = np.dtype([("weight", int), ("cost", float)])
(4)                 >>> A = nx.to_numpy_array(G, dtype=dtype, weight=None)
(4)                 >>> A["weight"]
(4)                 array([[ 0, 10,  0,  0],
(11)                       [10,  0,  1,  0],
(11)                       [ 0,  1,  0,  3],
(11)                       [ 0,  0,  3,  0]])
(4)                 >>> A["cost"]
(4)                 array([[ 0.,  1.,  0.,  0.],
(11)                       [ 1.,  0.,  5.,  0.],
(11)                       [ 0.,  5.,  0., -4.],
(11)                       [ 0.,  0., -4.,  0.]])
(4)                 As stated above, the argument "nonedge" is useful especially when there
are
(4)                 actually edges with weight 0 in the graph. Setting a nonedge value
different than 0,
(4)                 makes it much clearer to differentiate such 0-weighted edges and actual
nonedge values.
(4)                 >>> G = nx.Graph()
(4)                 >>> G.add_edge(3, 1, weight=2)
(4)                 >>> G.add_edge(2, 0, weight=0)
(4)                 >>> G.add_edge(2, 1, weight=0)
(4)                 >>> G.add_edge(3, 0, weight=1)
(4)                 >>> nx.to_numpy_array(G, nonedge=-1.0)

(8)                     An adjacency matrix representation of a graph
(4)                 parallel_edges : Boolean
(8)                     If this is True, `create_using` is a multigraph, and `A` is an
(8)                     integer array, then entry *(i, j)* in the array is interpreted as the
(8)                     number of parallel edges joining vertices *i* and *j* in the graph.
(8)                     If it is False, then the entries in the array are interpreted as
(8)                     the weight of a single edge joining the vertices.
(4)                 create_using : NetworkX graph constructor, optional (default=nx.Graph)
(7)                    Graph type to create. If graph instance, then cleared before populated.
(4)                 edge_attr : String, optional (default="weight")
(8)                     The attribute to which the array values are assigned on each edge. If
(8)                     it is None, edge attributes will not be assigned.
(4)                 Notes
(4)                 -----
(4)                 For directed graphs, explicitly mention create_using=nx.DiGraph,
(4)                 and entry i,j of A corresponds to an edge from i to j.
(4)                 If `create_using` is :class:`networkx.MultiGraph` or
(4)                 :class:`networkx.MultiDiGraph`, `parallel_edges` is True, and the
(4)                 entries of `A` are of type :class:`int`, then this function returns a
(4)                 multigraph (of the same type as `create_using`) with parallel edges.
(4)                 If `create_using` indicates an undirected multigraph, then only the edges
(4)                 indicated by the upper triangle of the array `A` will be added to the
(4)                 graph.
(4)                 If `edge_attr` is Falsy (False or None), edge attributes will not be
(4)                 assigned, and the array data will be treated like a binary mask of
(4)                 edge presence or absence. Otherwise, the attributes will be assigned
(4)                 as follows:
(4)                 If the NumPy array has a single data type for each array entry it
(4)                 will be converted to an appropriate Python data type.
(4)                 If the NumPy array has a user-specified compound data type the names
```

```
    of the data fields will be used as attribute keys in the resulting
    NetworkX graph.
    See Also
    --------
    to_numpy_array
    Examples
    --------
    Simple integer weights on edges:
    >>> import numpy as np
    >>> A = np.array([[1, 1], [2, 1]])
    >>> G = nx.from_numpy_array(A)
    >>> G.edges(data=True)
    EdgeDataView([(0, 0, {'weight': 1}), (0, 1, {'weight': 2}), (1, 1, {'weight': 1})])
    If `create_using` indicates a multigraph and the array has only integer
    entries and `parallel_edges` is False, then the entries will be treated
    as weights for edges joining the nodes (without creating parallel edges):
    >>> A = np.array([[1, 1], [1, 2]])
    >>> G = nx.from_numpy_array(A, create_using=nx.MultiGraph)
    >>> G[1][1]
    AtlasView({0: {'weight': 2}})
    If `create_using` indicates a multigraph and the array has only integer
    entries and `parallel_edges` is True, then the entries will be treated
    as the number of parallel edges joining those two vertices:
    >>> A = np.array([[1, 1], [1, 2]])
    >>> temp = nx.MultiGraph()
    >>> G = nx.from_numpy_array(A, parallel_edges=True, create_using=temp)
    >>> G[1][1]
    AtlasView({0: {'weight': 1}, 1: {'weight': 1}})
    User defined compound data type on edges:
    >>> dt = [("weight", float), ("cost", int)]
    >>> A = np.array([[(1.0, 2)]], dtype=dt)
    >>> G = nx.from_numpy_array(A)
    >>> G.edges()
    EdgeView([(0, 0)])
    >>> G[0][0]["cost"]
    2
    >>> G[0][0]["weight"]
    1.0

File 6 - lazy_imports.py:

```
1: (0)              import importlib
2: (0)              import importlib.util
3: (0)              import inspect
4: (0)              import os
5: (0)              import sys
6: (0)              import types
7: (0)              __all__ = ["attach", "_lazy_import"]
8: (0)              def attach(module_name, submodules=None, submod_attrs=None):
9: (4)                  """Attach lazily loaded submodules, and functions or other attributes.
10: (4)                 Typically, modules import submodules and attributes as follows::
```

```
 11: (6)                    import mysubmodule
 12: (6)                    import anothersubmodule
 13: (6)                    from .foo import someattr
 14: (4)                  The idea of  this function is to replace the `__init__.py`
 15: (4)                  module's `__getattr__`, `__dir__`, and `__all__` attributes such that
 16: (4)                  all imports work exactly the way they normally would, except that the
 17: (4)                  actual import is delayed until the resulting module object is first used.
 18: (4)                  The typical way to call this function, replacing the above imports, is::
 19: (6)                    __getattr__, __lazy_dir__, __all__ = lazy.attach(
 20: (10)                       __name__, ["mysubmodule", "anothersubmodule"], {"foo": "someattr"}
 21: (6)                    )
 22: (4)                  This functionality requires Python 3.7 or higher.
 23: (4)                  Parameters
 24: (4)                  ----------
 25: (4)                  module_name : str
 26: (8)                      Typically use __name__.

 75: (0)              def _lazy_import(fullname):
 76: (4)                  """Return a lazily imported proxy for a module or library.
```

```
 77: (4)                 Warning
 78: (4)                 -------
 79: (4)                 Importing using this function can currently cause trouble
 80: (4)                 when the user tries to import from a subpackage of a module before
 81: (4)                 the package is fully imported. In particular, this idiom may not work:
 82: (6)                   np = lazy_import("numpy")
 83: (6)                   from numpy.lib import recfunctions
 84: (4)                 This is due to a difference in the way Python's LazyLoader handles
 85: (4)                 subpackage imports compared to the normal import process. Hopefully
 86: (4)                 we will get Python's LazyLoader to fix this, or find a workaround.
 87: (4)                 In the meantime, this is a potential problem.
 88: (4)                 The workaround is to import numpy before importing from the subpackage.
 89: (4)                 Notes
 90: (4)                 -----
 91: (4)                 We often see the following pattern::
 92: (6)                   def myfunc():
 93: (10)                      import scipy as sp
 94: (10)                      sp.argmin(...)
 95: (10)                      ....
 96: (4)                 This is to prevent a library, in this case `scipy`, from being
 97: (4)                 imported at function definition time, since that can be slow.
 98: (4)                 This function provides a proxy module that, upon access, imports
 99: (4)                 the actual module.  So the idiom equivalent to the above example is::
 100: (6)                  sp = lazy.load("scipy")
 101: (6)                  def myfunc():
 102: (10)                     sp.argmin(...)
 103: (10)                     ....
 104: (4)                The initial import time is fast because the actual import is delayed
 105: (4)                until the first attribute is requested. The overall import time may
 106: (4)                decrease as well for users that don't make use of large portions
 107: (4)                of the library.
 108: (4)                Parameters
 109: (4)                ----------
 110: (4)                fullname : str
 111: (8)                    The full name of the package or subpackage to import.  For example::
 112: (10)                     sp = lazy.load("scipy")  # import scipy as sp
 113: (10)                     spla = lazy.load("scipy.linalg")  # import scipy.linalg as spla
 114: (4)                Returns
 115: (4)                -------
 116: (4)                pm : importlib.util._LazyModule
 117: (8)                    Proxy module. Can be used like any regularly imported module.
 118: (8)                    Actual loading of the module occurs upon first attribute request.
 119: (4)                """

File 7 - relabel.py:

```
1: (0)              import networkx as nx
2: (0)              __all__ = ["convert_node_labels_to_integers", "relabel_nodes"]
3: (0)              @nx._dispatchable(
4: (4)                  preserve_all_attrs=True, mutates_input={"not copy": 2}, returns_graph=True
5: (0)              )
6: (0)              def relabel_nodes(G, mapping, copy=True):
7: (4)                  """Relabel the nodes of the graph G according to a given mapping.
8: (4)                  The original node ordering may not be preserved if `copy` is `False` and
the
9: (4)                  mapping includes overlap between old and new labels.
10: (4)                 Parameters
11: (4)                 ----------
12: (4)                 G : graph
13: (7)                    A NetworkX graph
14: (4)                 mapping : dictionary
15: (7)                    A dictionary with the old labels as keys and new labels as values.
16: (7)                    A partial mapping is allowed. Mapping 2 nodes to a single node is
allowed.
17: (7)                    Any non-node keys in the mapping are ignored.
18: (4)                 copy : bool (optional, default=True)
19: (7)                    If True return a copy, or if False relabel the nodes in place.
20: (4)                 Examples
21: (4)                 --------
22: (4)                 To create a new graph with nodes relabeled according to a given
23: (4)                 dictionary:
24: (4)                 >>> G = nx.path_graph(3)
25: (4)                 >>> sorted(G)
26: (4)                 [0, 1, 2]
27: (4)                 >>> mapping = {0: "a", 1: "b", 2: "c"}
28: (4)                 >>> H = nx.relabel_nodes(G, mapping)
29: (4)                 >>> sorted(H)
30: (4)                 ['a', 'b', 'c']
31: (4)                 Nodes can be relabeled with any hashable object, including numbers
32: (4)                 and strings:
33: (4)                 >>> import string
34: (4)                 >>> G = nx.path_graph(26)  # nodes are integers 0 through 25
35: (4)                 >>> sorted(G)[:3]
36: (4)                 [0, 1, 2]
37: (4)                 >>> mapping = dict(zip(G, string.ascii_lowercase))
38: (4)                 >>> G = nx.relabel_nodes(G, mapping)  # nodes are characters a through z
39: (4)                 >>> sorted(G)[:3]
40: (4)                 ['a', 'b', 'c']
41: (4)                 >>> mapping = dict(zip(G, range(1, 27)))
42: (4)                 >>> G = nx.relabel_nodes(G, mapping)  # nodes are integers 1 through 26
43: (4)                 >>> sorted(G)[:3]
44: (4)                 [1, 2, 3]
45: (4)                 To perform a partial in-place relabeling, provide a dictionary
46: (4)                 mapping only a subset of the nodes, and set the `copy` keyword
47: (4)                 argument to False:
48: (4)                 >>> G = nx.path_graph(3)  # nodes 0-1-2
49: (4)                 >>> mapping = {0: "a", 1: "b"}  # 0->'a' and 1->'b'
50: (4)                 >>> G = nx.relabel_nodes(G, mapping, copy=False)
51: (4)                 >>> sorted(G, key=str)
52: (4)                 [2, 'a', 'b']
53: (4)                 A mapping can also be given as a function:
54: (4)                 >>> G = nx.path_graph(3)
55: (4)                 >>> H = nx.relabel_nodes(G, lambda x: x**2)
56: (4)                 >>> list(H)
57: (4)                 [0, 1, 4]
58: (4)                 In a multigraph, relabeling two or more nodes to the same new node
59: (4)                 will retain all edges, but may change the edge keys in the process:
60: (4)                 >>> G = nx.MultiGraph()
61: (4)                 >>> G.add_edge(0, 1, value="a")  # returns the key for this edge
62: (4)                 0
63: (4)                 >>> G.add_edge(0, 2, value="b")
64: (4)                 0
```

```
65: (4)                 >>> G.add_edge(0, 3, value="c")
66: (4)                 0
67: (4)                 >>> mapping = {1: 4, 2: 4, 3: 4}
68: (4)                 >>> H = nx.relabel_nodes(G, mapping, copy=True)
69: (4)                 >>> print(H[0])
70: (4)                 {4: {0: {'value': 'a'}, 1: {'value': 'b'}, 2: {'value': 'c'}}}
71: (4)                 This works for in-place relabeling too:
72: (4)                 >>> G = nx.relabel_nodes(G, mapping, copy=False)
73: (4)                 >>> print(G[0])
74: (4)                 {4: {0: {'value': 'a'}, 1: {'value': 'b'}, 2: {'value': 'c'}}}
75: (4)                 Notes
76: (4)                 -----
77: (4)                 Only the nodes specified in the mapping will be relabeled.
78: (4)                 Any non-node keys in the mapping are ignored.
79: (4)                 The keyword setting copy=False modifies the graph in place.
80: (4)                 Relabel_nodes avoids naming collisions by building a
81: (4)                 directed graph from ``mapping`` which specifies the order of
82: (4)                 relabelings. Naming collisions, such as a->b, b->c, are ordered
83: (4)                 such that "b" gets renamed to "c" before "a" gets renamed "b".
84: (4)                 In cases of circular mappings (e.g. a->b, b->a), modifying the
85: (4)                 graph is not possible in-place and an exception is raised.
86: (4)                 In that case, use copy=True.
87: (4)                 If a relabel operation on a multigraph would cause two or more
88: (4)                 edges to have the same source, target and key, the second edge must
89: (4)                 be assigned a new key to retain all edges. The new key is set
90: (4)                 to the lowest non-negative integer not already used as a key
91: (4)                 for edges between these two nodes. Note that this means non-numeric
92: (4)                 keys may be replaced by numeric keys.
93: (4)                 See Also

18: (0)             def find_asteroidal_triple(G):
19: (4)                 r"""Find an asteroidal triple in the given graph.
20: (4)                 An asteroidal triple is a triple of non-adjacent vertices such that
21: (4)                 there exists a path between any two of them which avoids the closed
22: (4)                 neighborhood of the third. It checks all independent triples of vertices
23: (4)                 and whether they are an asteroidal triple or not. This is done with the
24: (4)                 help of a data structure called a component structure.
25: (4)                 A component structure encodes information about which vertices belongs to
26: (4)                 the same connected component when the closed neighborhood of a given
vertex
27: (4)                 is removed from the graph. The algorithm used to check is the trivial
28: (4)                 one, outlined in [1]_, which has a runtime of
29: (4)                 :math:`O(|V||\overline{E} + |V||E|)`, where the second term is the
30: (4)                 creation of the component structure.
31: (4)                 Parameters
```

```
    ----------
    G : NetworkX Graph
        The graph to check whether is AT-free or not
    Returns
    -------
    list or None
        An asteroidal triple is returned as a list of nodes. If no asteroidal
        triple exists, i.e. the graph is AT-free, then None is returned.
        The returned value depends on the certificate parameter. The default
        option is a bool which is True if the graph is AT-free, i.e. the
        given graph contains no asteroidal triples, and False otherwise, i.e.
        if the graph contains at least one asteroidal triple.
    Notes
    -----
    The component structure and the algorithm is described in [1]_. The current
    implementation implements the trivial algorithm for simple graphs.

9: (4)                  """Returns the chain decomposition of a graph.
10: (4)                 The *chain decomposition* of a graph with respect a depth-first
11: (4)                 search tree is a set of cycles or paths derived from the set of
12: (4)                 fundamental cycles of the tree in the following manner. Consider
13: (4)                 each fundamental cycle with respect to the given tree, represented
14: (4)                 as a list of edges beginning with the nontree edge oriented away
15: (4)                 from the root of the tree. For each fundamental cycle, if it
16: (4)                 overlaps with any previous fundamental cycle, just take the initial
17: (4)                 non-overlapping segment, which is a path instead of a cycle. Each
18: (4)                 cycle or path is called a *chain*. For more information, see [1]_.
19: (4)                 Parameters
```

```
(4)     ----------
(4)     G : undirected graph
(4)     root : node (optional)
(7)        A node in the graph `G`. If specified, only the chain
(7)        decomposition for the connected component containing this node
(7)        will be returned. This node indicates the root of the depth-first
(7)        search tree.
(4)     Yields
(4)     ------
(4)     chain : list
(7)        A list of edges representing a chain. There is no guarantee on
(7)        the orientation of the edges in each chain (for example, if a
(7)        chain includes the edge joining nodes 1 and 2, the chain may
(7)        include either (1, 2) or (2, 1)).
(4)     Raises
(4)     ------
(4)     NodeNotFound
(7)        If `root` is not in the graph `G`.
(4)     Examples
(4)     --------
(4)     >>> G = nx.Graph([(0, 1), (1, 4), (3, 4), (3, 5), (4, 5)])
(4)     >>> list(nx.chain_decomposition(G))
(4)     [[(4, 5), (5, 3), (3, 4)]]
(4)     Notes
(4)     -----
(4)     The worst-case running time of this implementation is linear in the
(4)     number of nodes and number of edges [1]_.

101: (8)                    containing all the nodes in `nodes` are returned. The order of
102: (8)                    cliques is arbitrary.
103: (4)                Raises
104: (4)                ------
105: (4)                ValueError
106: (8)                    If `nodes` is not a clique.
107: (4)                Examples
108: (4)                --------
109: (4)                >>> from pprint import pprint  # For nice dict formatting
110: (4)                >>> G = nx.karate_club_graph()
```

```
(4)                >>> sum(1 for c in nx.find_cliques(G))  # The number of maximal cliques in
G
(4)                36
(4)                >>> max(nx.find_cliques(G), key=len)  # The largest maximal clique in G
(4)                [0, 1, 2, 3, 13]
(4)                The size of the largest maximal clique is known as the *clique number* of
(4)                the graph, which can be found directly with:
(4)                >>> max(len(c) for c in nx.find_cliques(G))
(4)                5
(4)                One can also compute the number of maximal cliques in `G` that contain a
given
(4)                node. The following produces a dictionary keyed by node whose
(4)                values are the number of maximal cliques in `G` that contain the node:
(4)                >>> pprint({n: sum(1 for c in nx.find_cliques(G) if n in c) for n in G})
(4)                {0: 13,
(5)                 1: 6,
(5)                 2: 7,
(5)                 3: 3,
(5)                 4: 2,
(5)                 5: 3,
(5)                 6: 3,
(5)                 7: 1,
(5)                 8: 3,
(5)                 9: 2,
(5)                 10: 2,
(5)                 11: 1,
(5)                 12: 1,
(5)                 13: 2,
(5)                 14: 1,
(5)                 15: 1,
(5)                 16: 1,
(5)                 17: 1,
(5)                 18: 1,
(5)                 19: 2,
(5)                 20: 1,
(5)                 21: 1,
(5)                 22: 1,
(5)                 23: 3,
(5)                 24: 2,
(5)                 25: 2,
(5)                 26: 1,
(5)                 27: 3,
(5)                 28: 2,
(5)                 29: 2,
(5)                 30: 2,
(5)                 31: 4,
(5)                 32: 9,
(5)                 33: 14}
(4)                Or, similarly, the maximal cliques in `G` that contain a given node.
(4)                For example, the 4 maximal cliques that contain node 31:
(4)                >>> [c for c in nx.find_cliques(G) if 31 in c]
(4)                [[0, 31], [33, 32, 31], [33, 28, 31], [24, 25, 31]]

(8)                    A recursive version of the same algorithm.
(4)                Notes
(4)                -----
(4)                To obtain a list of all maximal cliques, use
(4)                `list(find_cliques(G))`. However, be aware that in the worst-case,
(4)                the length of this list can be exponential in the number of nodes in
(4)                the graph. This function avoids storing all cliques in memory by
(4)                only keeping current candidate node lists in memory during its search.
(4)                This implementation is based on the algorithm published by Bron and
(4)                Kerbosch (1973) [1]_, as adapted by Tomita, Tanaka and Takahashi
(4)                (2006) [2]_ and discussed in Cazals and Karande (2008) [3]_. It
(4)                essentially unrolls the recursion used in the references to avoid
(4)                issues of recursion stack depth (for a recursive implementation, see
(4)                :func:`find_cliques_recursive`).

240: (8)                    pass
241: (0)            @nx._dispatchable
242: (0)            def find_cliques_recursive(G, nodes=None):
243: (4)                """Returns all maximal cliques in a graph.
244: (4)                For each node *v*, a *maximal clique for v* is a largest complete
```

```
    subgraph containing *v*. The largest maximal clique is sometimes
    called the *maximum clique*.
    This function returns an iterator over cliques, each of which is a
    list of nodes. It is a recursive implementation, so may suffer from
    recursion depth issues, but is included for pedagogical reasons.
    For a non-recursive implementation, see :func:`find_cliques`.
    This function accepts a list of `nodes` and only the maximal cliques
    containing all of these `nodes` are returned. It can considerably speed up
    the running time if some specific cliques are desired.
    Parameters
    ----------
    G : NetworkX graph
    nodes : list, optional (default=None)
        If provided, only yield *maximal cliques* containing all nodes in `nodes`.

        If `nodes` isn't a clique itself, a ValueError is raised.
    Returns
    -------
    iterator
        An iterator over maximal cliques, each of which is a list of
        nodes in `G`. If `nodes` is provided, only the maximal cliques
        containing all the nodes in `nodes` are yielded. The order of
        cliques is arbitrary.
    Raises
    ------
    ValueError
        If `nodes` is not a clique.
    See Also
    --------
    find_cliques
        An iterative version of the same algorithm. See docstring for examples.
    Notes
    -----
    To obtain a list of all maximal cliques, use
    `list(find_cliques_recursive(G))`. However, be aware that in the
    worst-case, the length of this list can be exponential in the number
    of nodes in the graph. This function avoids storing all cliques in memory
    by only keeping current candidate node lists in memory during its search.
    This implementation is based on the algorithm published by Bron and
    Kerbosch (1973) [1]_, as adapted by Tomita, Tanaka and Takahashi
    (2006) [2]_ and discussed in Cazals and Karande (2008) [3]_. For a
    non-recursive implementation, see :func:`find_cliques`.
    This algorithm ignores self-loops and parallel edges, since cliques
    are not conventionally defined with such edges.

(4)                 In the returned bipartite graph, the "bottom" nodes are the nodes of
(4)                 `G` and the "top" nodes represent the maximal cliques of `G`.
(4)                 There is an edge from node *v* to clique *C* in the returned graph
(4)                 if and only if *v* is an element of *C*.
(4)                 Parameters
(4)                 ----------
```

```
    G : NetworkX graph
        An undirected graph.
    fpos : bool
        If True or not None, the returned graph will have an
        additional attribute, `pos`, a dictionary mapping node to
        position in the Euclidean plane.
    create_using : NetworkX graph constructor, optional (default=nx.Graph)
       Graph type to create. If graph instance, then cleared before populated.
    Returns
    -------
    NetworkX graph
        A bipartite graph whose "bottom" set is the nodes of the graph
        `G`, whose "top" set is the cliques of `G`, and whose edges
        join nodes of `G` to the cliques that contain them.
        The nodes of the graph `G` have the node attribute
        'bipartite' set to 1 and the nodes representing cliques
        have the node attribute 'bipartite' set to 0, as is the
        convention for bipartite graphs in NetworkX.

(4)                 weight : int
```

```
578: (8)                the weight of a maximum weight clique
579: (4)            Notes
580: (4)            -----
581: (4)            The implementation is recursive, and therefore it may run into recursion
582: (4)            depth issues if G contains a clique whose number of nodes is close to the
583: (4)            recursion depth limit.
584: (4)            At each search node, the algorithm greedily constructs a weighted
585: (4)            independent set cover of part of the graph in order to find a small set of
586: (4)            nodes on which to branch.  The algorithm is very similar to the algorithm
587: (4)            of Tavares et al. [1]_, other than the fact that the NetworkX version does
588: (4)            not use bitsets.  This style of algorithm for maximum weight clique (and
589: (4)            maximum weight independent set, which is the same problem but on the
590: (4)            complement graph) has a decades-long history.  See Algorithm B of Warren
591: (4)            and Hicks [2]_ and the references in that paper.

236: (4)                r"""Compute the clustering coefficient for nodes.
237: (4)                For unweighted graphs, the clustering of a node :math:`u`
238: (4)                is the fraction of possible triangles through that node that exist,
239: (4)                .. math::
240: (6)                  c_u = \frac{2 T(u)}{deg(u)(deg(u)-1)},
241: (4)                where :math:`T(u)` is the number of triangles through node :math:`u` and
242: (4)                :math:`deg(u)` is the degree of :math:`u`.
243: (4)                For weighted graphs, there are several ways to define clustering [1]_.
244: (4)                the one used here is defined
245: (4)                as the geometric average of the subgraph edge weights [2]_,
246: (4)                .. math::
247: (7)                   c_u = \frac{1}{deg(u)(deg(u)-1))}
248: (13)                        \sum_{vw} (\hat{w}_{uv} \hat{w}_{uw} \hat{w}_{vw})^{1/3}.
249: (4)                The edge weights :math:`\hat{w}_{uv}` are normalized by the maximum weight
250: (4)                in the network :math:`\hat{w}_{uv} = w_{uv}/\max(w)`.
251: (4)                The value of :math:`c_u` is assigned to 0 if :math:`deg(u) < 2`.
252: (4)                Additionally, this weighted definition has been generalized to support
negative edge weights [3]_.
253: (4)                For directed graphs, the clustering is similarly defined as the fraction
254: (4)                of all possible directed triangles or geometric average of the subgraph
255: (4)                edge weights for unweighted and weighted directed graph respectively [4]_.
256: (4)                .. math::
257: (7)                   c_u = \frac{T(u)}{2(deg^{tot}(u)(deg^{tot}(u)-1) -
2deg^{\leftrightarrow}(u))},
258: (4)                where :math:`T(u)` is the number of directed triangles through node
259: (4)                :math:`u`, :math:`deg^{tot}(u)` is the sum of in degree and out degree of
260: (4)                :math:`u` and :math:`deg^{\leftrightarrow}(u)` is the reciprocal degree of
261: (4)                :math:`u`.

(4)                 three vertices where every edge is incident to at least `k-2` triangles.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX graph
(6)                   An undirected graph
(4)                 k : int
(6)                   The order of the truss
(4)                 Returns
(4)                 -------
(4)                 H : NetworkX graph
(6)                   The k-truss subgraph
(4)                 Raises
(4)                 ------
(4)                 NetworkXNotImplemented
(6)                   If `G` is a multigraph or directed graph or if it contains self loops.
(4)                 Notes
```

```
    -----
    A k-clique is a (k-2)-truss and a k-truss is a (k+1)-core.
    Graph, node, and edge attributes are copied to the subgraph.
    K-trusses were originally defined in [2] which states that the k-truss
    is the maximal induced subgraph where each edge belongs to at least
    `k-2` triangles. A more recent paper, [1], uses a slightly different
    definition requiring that each edge belong to at least `k` triangles.
    This implementation uses the original definition of `k-2` triangles.
    Examples
    --------
    >>> degrees = [0, 1, 2, 2, 2, 2, 3]
    >>> H = nx.havel_hakimi_graph(degrees)
    >>> H.degree
    DegreeView({0: 1, 1: 2, 2: 2, 3: 2, 4: 2, 5: 3, 6: 0})
    >>> nx.k_truss(H, k=2).nodes
    NodeView((0, 1, 2, 3, 4, 5))

11: (4)                 """Returns the min cardinality edge cover of the graph as a set of edges.
12: (4)                 A smallest edge cover can be found in polynomial time by finding
13: (4)                 a maximum matching and extending it greedily so that all nodes
14: (4)                 are covered. This function follows that process. A maximum matching
15: (4)                 algorithm can be specified for the first step of the algorithm.
16: (4)                 The resulting set may return a set with one 2-tuple for each edge,
17: (4)                 (the usual case) or with both 2-tuples `(u, v)` and `(v, u)` for
18: (4)                 each edge. The latter is only done when a bipartite matching algorithm
19: (4)                 is specified as `matching_algorithm`.
20: (4)                 Parameters
21: (4)                 ----------
22: (4)                 G : NetworkX graph
23: (8)                     An undirected graph.
24: (4)                 matching_algorithm : function
25: (8)                     A function that returns a maximum cardinality matching for `G`.
26: (8)                     The function must take one input, the graph `G`, and return
27: (8)                     either a set of edges (with only one direction for the pair of nodes)
28: (8)                     or a dictionary mapping each node to its mate. If not specified,
29: (8)                     :func:`~networkx.algorithms.matching.max_weight_matching` is used.
30: (8)                     Common bipartite matching functions include
31: (8)                     :func:`~networkx.algorithms.bipartite.matching.hopcroft_karp_matching`
32: (8)                     or
33: (8)                     :func:`~networkx.algorithms.bipartite.matching.eppstein_matching`.
34: (4)                 Returns
35: (4)                 -------
36: (4)                 min_cover : set
37: (8)                     A set of the edges in a minimum edge cover in the form of tuples.
38: (8)                     It contains only one of the equivalent 2-tuples `(u, v)` and `(v, u)`
39: (8)                     for each edge. If a bipartite method is used to compute the matching,
40: (8)                     the returned set contains both the 2-tuples `(u, v)` and `(v, u)`
41: (8)                     for each edge of a minimum edge cover.
42: (4)                 Examples
43: (4)                 --------
44: (4)                 >>> G = nx.Graph([(0, 1), (0, 2), (0, 3), (1, 2), (1, 3)])

91: (0)             @nx._dispatchable
92: (0)             def simple_cycles(G, length_bound=None):
93: (4)                 """Find simple cycles (elementary circuits) of a graph.
94: (4)                 A `simple cycle`, or `elementary circuit`, is a closed path where
95: (4)                 no node appears twice.  In a directed graph, two simple cycles are
distinct
96: (4)                 if they are not cyclic permutations of each other.  In an undirected
graph,
97: (4)                 two simple cycles are distinct if they are not cyclic permutations of each
98: (4)                 other nor of the other's reversal.
99: (4)                 Optionally, the cycles are bounded in length.  In the unbounded case, we
use
100: (4)                a nonrecursive, iterator/generator version of Johnson's algorithm [1]_.
In
101: (4)                the bounded case, we use a version of the algorithm of Gupta and
102: (4)                Suzumura[2]_. There may be better algorithms for some cases [3]_ [4]_
[5]_.
103: (4)                The algorithms of Johnson, and Gupta and Suzumura, are enhanced by some
104: (4)                well-known preprocessing techniques.  When G is directed, we restrict our
105: (4)                attention to strongly connected components of G, generate all simple
cycles
106: (4)                containing a certain node, remove that node, and further decompose the
107: (4)                remainder into strongly connected components.  When G is undirected, we
108: (4)                restrict our attention to biconnected components, generate all simple
cycles
109: (4)                containing a particular edge, remove that edge, and further decompose the
110: (4)                remainder into biconnected components.
111: (4)                Note that multigraphs are supported by this function -- and in undirected
112: (4)                multigraphs, a pair of parallel edges is considered a cycle of length 2.
113: (4)                Likewise, self-loops are considered to be cycles of length 1.  We define
114: (4)                cycles as sequences of nodes; so the presence of loops and parallel edges
115: (4)                does not change the number of simple cycles in a graph.
116: (4)                Parameters
117: (4)                ----------
118: (4)                G : NetworkX DiGraph
119: (7)                   A directed graph
120: (4)                length_bound : int or None, optional (default=None)
```

```
   If length_bound is an int, generate all simple cycles of G with length at
   most length_bound.  Otherwise, generate all simple cycles of G.
Yields
------
list of nodes
   Each cycle is represented by a list of nodes along the cycle.
Examples
--------
>>> edges = [(0, 0), (0, 1), (0, 2), (1, 2), (2, 0), (2, 1), (2, 2)]
>>> G = nx.DiGraph(edges)
>>> sorted(nx.simple_cycles(G))
[[0], [0, 1, 2], [0, 2], [1, 2], [2]]
To filter the cycles so that they don't include certain nodes or edges,
copy your graph and eliminate those nodes or edges before calling.
For example, to exclude self-loops from the above example:
>>> H = G.copy()
>>> H.remove_edges_from(nx.selfloop_edges(G))
>>> sorted(nx.simple_cycles(H))
[[0, 1, 2], [0, 2], [1, 2]]
Notes
-----
When length_bound is None, the time complexity is $O((n+e)(c+1))$ for $n$
nodes, $e$ edges and $c$ simple circuits.  Otherwise, when length_bound > 1,
the time complexity is $O((c+n)(k-1)d^k)$ where $d$ is the average degree of
the nodes of G and $k$ = length_bound.
Raises
------
ValueError
    when length_bound < 0.

397: (4)                A `simple cycle` is a closed path where no node appears twice.  In a
simple
398: (4)                cycle, a `chord` is an additional edge between two nodes in the cycle.  A
399: (4)                `chordless cycle` is a simple cycle without chords.  Said differently, a
400: (4)                chordless cycle is a cycle C in a graph G where the number of edges in the
401: (4)                induced graph G[C] is equal to the length of `C`.
402: (4)                Note that some care must be taken in the case that G is not a simple graph
403: (4)                nor a simple digraph.  Some authors limit the definition of chordless
cycles
404: (4)                to have a prescribed minimum length; we do not.
405: (8)                    1. We interpret self-loops to be chordless cycles, except in
multigraphs
406: (11)                      with multiple loops in parallel.  Likewise, in a chordless cycle of
407: (11)                      length greater than 1, there can be no nodes with self-loops.
408: (8)                    2. We interpret directed two-cycles to be chordless cycles, except in
409: (11)                      multi-digraphs when any edge in a two-cycle has a parallel copy.
410: (8)                    3. We interpret parallel pairs of undirected edges as two-cycles,
except
411: (11)                      when a third (or more) parallel edge exists between the two nodes.
412: (8)                    4. Generalizing the above, edges with parallel clones may not occur in
413: (11)                      chordless cycles.
414: (4)                In a directed graph, two chordless cycles are distinct if they are not
415: (4)                cyclic permutations of each other.  In an undirected graph, two chordless
416: (4)                cycles are distinct if they are not cyclic permutations of each other nor
of
417: (4)                the other's reversal.
418: (4)                Optionally, the cycles are bounded in length.
419: (4)                We use an algorithm strongly inspired by that of Dias et al [1]_.  It has
420: (4)                been modified in the following ways:
421: (8)                    1. Recursion is avoided, per Python's limitations
422: (8)                    2. The labeling function is not necessary, because the starting paths
423: (12)                       are chosen (and deleted from the host graph) to prevent multiple
424: (12)                       occurrences of the same path
425: (8)                    3. The search is optionally bounded at a specified length
426: (8)                    4. Support for directed graphs is provided by extending cycles along
427: (12)                       forward edges, and blocking nodes along forward and reverse edges
428: (8)                    5. Support for multigraphs is provided by omitting digons from the set
429: (12)                       of forward edges
430: (4)                Parameters
431: (4)                ----------
432: (4)                G : NetworkX DiGraph
433: (7)                   A directed graph

(4)                 This algorithm is strongly inspired by that of Dias et al [1]_.  It has
been
(4)                 modified in the following ways:
(8)                     1. Recursion is avoided, per Python's limitations
(8)                     2. The labeling function is not necessary, because the starting paths
(12)                        are chosen (and deleted from the host graph) to prevent multiple
(12)                        occurrences of the same path
(8)                     3. The search is optionally bounded at a specified length
(8)                     4. Support for directed graphs is provided by extending cycles along
(12)                        forward edges, and blocking nodes along forward and reverse edges
(8)                     5. Support for multigraphs is provided by omitting digons from the set
(12)                        of forward edges
(4)                 Parameters
(4)                 ----------
(4)                 F : _NeighborhoodCache
(7)                    A graph of forward edges to follow in constructing cycles
(4)                 B : _NeighborhoodCache
(7)                    A graph of blocking edges to prevent the production of chordless cycles
(4)                 path : list
(7)                    A cycle prefix.  All cycles generated will begin with this prefix.
(4)                 length_bound : int
(7)                    A length bound.  All cycles generated will have length at most
length_bound.
(4)                 Yields
(4)                 ------
(4)                 list of nodes
(7)                    Each cycle is represented by a list of nodes along the cycle.

(0)             def recursive_simple_cycles(G):
(4)                 """Find simple cycles (elementary circuits) of a directed graph.
(4)                 A `simple cycle`, or `elementary circuit`, is a closed path where
(4)                 no node appears twice. Two elementary circuits are distinct if they
(4)                 are not cyclic permutations of each other.
(4)                 This version uses a recursive algorithm to build a list of cycles.
(4)                 You should probably use the iterator version called simple_cycles().
(4)                 Warning: This recursive version uses lots of RAM!
(4)                 It appears in NetworkX for pedagogical value.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX DiGraph
(7)                    A directed graph
(4)                 Returns
(4)                 -------
(4)                 A list of cycles, where each cycle is represented by a list of nodes
(4)                 along the cycle.
(4)                 Example:
(4)                 >>> edges = [(0, 0), (0, 1), (0, 2), (1, 2), (2, 0), (2, 1), (2, 2)]
(4)                 >>> G = nx.DiGraph(edges)
(4)                 >>> nx.recursive_simple_cycles(G)
(4)                 [[0], [2], [0, 1, 2], [0, 2], [1, 2]]
(4)                 Notes
(4)                 -----
(4)                 The implementation follows pp. 79-80 in [1]_.
(4)                 The time complexity is $O((n+e)(c+1))$ for $n$ nodes, $e$ edges and $c$
(4)                 elementary circuits.

(4)                 """Returns a cycle found via depth-first traversal.
(4)                 The cycle is a list of edges indicating the cyclic path.
(4)                 Orientation of directed edges is controlled by `orientation`.
(4)                 Parameters
(4)                 ----------
(4)                 G : graph
(8)                     A directed/undirected graph/multigraph.
(4)                 source : node, list of nodes
(8)                     The node from which the traversal begins. If None, then a source
(8)                     is chosen arbitrarily and repeatedly until all edges from each node in
(8)                     the graph are searched.
(4)                 orientation : None | 'original' | 'reverse' | 'ignore' (default: None)
(8)                     For directed graphs and directed multigraphs, edge traversals need not
(8)                     respect the original orientation of the edges.
(8)                     When set to 'reverse' every edge is traversed in the reverse
direction.
(8)                     When set to 'ignore', every edge is treated as undirected.
(8)                     When set to 'original', every edge is treated as directed.
(8)                     In all three cases, the yielded edge tuples add a last entry to
(8)                     indicate the direction in which that edge was traversed.
(8)                     If orientation is None, the yielded edge has no direction indicated.
(8)                     The direction is respected, but not reported.
(4)                 Returns
(4)                 -------
(4)                 edges : directed edges
(8)                     A list of directed edges indicating the path taken for the loop.
(8)                     If no cycle is found, then an exception is raised.
(8)                     For graphs, an edge is of the form `(u, v)` where `u` and `v`
(8)                     are the tail and head of the edge as determined by the traversal.
(8)                     For multigraphs, an edge is of the form `(u, v, key)`, where `key` is

(8)                     are always in the order of the actual directed edge.
(8)                     If orientation is not None then the edge tuple is extended to include
(8)                     the direction of traversal ('forward' or 'reverse') on that edge.
(4)                 Raises
```

```
    ------
    NetworkXNoCycle
        If no cycle was found.
    Examples
    --------
    In this example, we construct a DAG and find, in the first call, that there
    are no directed cycles, and so an exception is raised. In the second call,
    we ignore edge orientations and find that there is an undirected cycle.
    Note that the second call finds a directed cycle while effectively
    traversing an undirected graph, and so, we found an "undirected cycle".
    This means that this DAG structure does not form a directed tree (which
    is also known as a polytree).
    >>> G = nx.DiGraph([(0, 1), (0, 2), (1, 2)])
    >>> nx.find_cycle(G, orientation="original")
    Traceback (most recent call last):
        ...

File 22 - d_separation.py:

```
1: (0)              """
2: (0)              Algorithm for testing d-separation in DAGs.
3: (0)              *d-separation* is a test for conditional independence in probability
4: (0)              distributions that can be factorized using DAGs.  It is a purely
5: (0)              graphical test that uses the underlying graph and makes no reference
6: (0)              to the actual distribution parameters.  See [1]_ for a formal
7: (0)              definition.
8: (0)              The implementation is based on the conceptually simple linear time
9: (0)              algorithm presented in [2]_.  Refer to [3]_, [4]_ for a couple of
10: (0)             alternative algorithms.
11: (0)             The functional interface in NetworkX consists of three functions:
12: (0)             - `find_minimal_d_separator` returns a minimal d-separator set ``z``.
13: (2)               That is, removing any node or nodes from it makes it no longer a d-
separator.
14: (0)             - `is_d_separator` checks if a given set is a d-separator.
15: (0)             - `is_minimal_d_separator` checks if a given set is a minimal d-separator.
16: (0)             D-separators
17: (0)             ------------
18: (0)             Here, we provide a brief overview of d-separation and related concepts that
19: (0)             are relevant for understanding it:
20: (0)             The ideas of d-separation and d-connection relate to paths being open or
blocked.
21: (0)             - A "path" is a sequence of nodes connected in order by edges. Unlike for most
22: (2)               graph theory analysis, the direction of the edges is ignored. Thus the path
23: (2)               can be thought of as a traditional path on the undirected version of the
graph.
24: (0)             - A "candidate d-separator" ``z`` is a set of nodes being considered as
25: (2)               possibly blocking all paths between two prescribed sets ``x`` and ``y`` of
nodes.
26: (2)               We refer to each node in the candidate d-separator as "known".
27: (0)             - A "collider" node on a path is a node that is a successor of its two
neighbor
28: (2)               nodes on the path. That is, ``c`` is a collider if the edge directions
29: (2)               along the path look like ``... u -> c <- v ...``.
30: (0)             - If a collider node or any of its descendants are "known", the collider
31: (2)               is called an "open collider". Otherwise it is a "blocking collider".
```

```
(0)             - Any path can be "blocked" in two ways. If the path contains a "known" node
(2)               that is not a collider, the path is blocked. Also, if the path contains a
(2)               collider that is not a "known" node, the path is blocked.
(0)             - A path is "open" if it is not blocked. That is, it is open if every node is
(2)               either an open collider or not a "known". Said another way, every
(2)               "known" in the path is a collider and every collider is open (has a
(2)               "known" as a inclusive descendant). The concept of "open path" is meant to
(2)               demonstrate a probabilistic conditional dependence between two nodes given
(2)               prescribed knowledge ("known" nodes).
(0)             - Two sets ``x`` and ``y`` of nodes are "d-separated" by a set of nodes ``z``
(2)               if all paths between nodes in ``x`` and nodes in ``y`` are blocked. That is,
(2)               if there are no open paths from any node in ``x`` to any node in ``y``.
(2)               Such a set ``z`` is a "d-separator" of ``x`` and ``y``.
(0)             - A "minimal d-separator" is a d-separator ``z`` for which no node or subset
(2)               of nodes can be removed with it still being a d-separator.
(0)             The d-separator blocks some paths between ``x`` and ``y`` but opens others.
(0)             Nodes in the d-separator block paths if the nodes are not colliders.
(0)             But if a collider or its descendant nodes are in the d-separation set, the
(0)             colliders are open, allowing a path through that collider.
(0)             Illustration of D-separation with examples
(0)             ----------------------------------------
(0)             A pair of two nodes, ``u`` and ``v``, are d-connected if there is a path
(0)             from ``u`` to ``v`` that is not blocked. That means, there is an open
(0)             path from ``u`` to ``v``.
(0)             For example, if the d-separating set is the empty set, then the following
paths are
(0)             open between ``u`` and ``v``:
(0)             - u <- n -> v
(0)             - u -> w -> ... -> n -> v
(0)             If  on the other hand, ``n`` is in the d-separating set, then ``n`` blocks
(0)             those paths between ``u`` and ``v``.
(0)             Colliders block a path if they and their descendants are not included
(0)             in the d-separating set. An example of a path that is blocked when the
(0)             d-separating set is empty is:
(0)             - u -> w -> ... -> n <- v
(0)             The node ``n`` is a collider in this path and is not in the d-separating set.
(0)             So ``n`` blocks this path. However, if ``n`` or a descendant of ``n`` is
(0)             included in the d-separating set, then the path through the collider
(0)             at ``n`` (... -> n <- ...) is "open".
(0)             D-separation is concerned with blocking all paths between nodes from ``x`` to
``y``.
(0)             A d-separating set between ``x`` and ``y`` is one where all paths are blocked.
(0)             D-separation and its applications in probability
(0)             ------------------------------------------------
(0)             D-separation is commonly used in probabilistic causal-graph models. D-
separation
(0)             connects the idea of probabilistic "dependence" with separation in a graph. If
(0)             one assumes the causal Markov condition [5]_, (every node is conditionally
(0)             independent of its non-descendants, given its parents) then d-separation
implies
(0)             conditional independence in probability distributions.
(0)             Symmetrically, d-connection implies dependence.
(0)             The intuition is as follows. The edges on a causal graph indicate which nodes
(0)             influence the outcome of other nodes directly. An edge from u to v
(0)             implies that the outcome of event ``u`` influences the probabilities for
(0)             the outcome of event ``v``. Certainly knowing ``u`` changes predictions for
``v``.
(0)             But also knowing ``v`` changes predictions for ``u``. The outcomes are
dependent.
(0)             Furthermore, an edge from ``v`` to ``w`` would mean that ``w`` and ``v`` are
dependent
(0)             and thus that ``u`` could indirectly influence ``w``.
(0)             Without any knowledge about the system (candidate d-separating set is empty)
(0)             a causal graph ``u -> v -> w`` allows all three nodes to be dependent. But
(0)             if we know the outcome of ``v``, the conditional probabilities of outcomes for
(0)             ``u`` and ``w`` are independent of each other. That is, once we know the
outcome
(0)             for ```v`, the probabilities for ``w`` do not depend on the outcome for ``u``.
(0)             This is the idea behind ``v`` blocking the path if it is "known" (in the
```

```
candidate
d-separating set).
The same argument works whether the direction of the edges are both
left-going and when both arrows head out from the middle. Having a "known"
node on a path blocks the collider-free path because those relationships
make the conditional probabilities independent.
The direction of the causal edges does impact dependence precisely in the
case of a collider e.g. ``u -> v <- w``. In that situation, both ``u`` and
``w``
influence ``v```. But they do not directly influence each other. So without
any
knowledge of any outcomes, ``u`` and ``w`` are independent. That is the idea
behind
colliders blocking the path. But, if ``v`` is known, the conditional
probabilities
of ``u`` and ``w`` can be dependent. This is the heart of Berkson's Paradox
[6]_.
For example, suppose ``u`` and ``w`` are boolean events (they either happen or
do not)
and ``v`` represents the outcome "at least one of ``u`` and ``w`` occur". Then
knowing
``v`` is true makes the conditional probabilities of ``u`` and ``w``
dependent.
Essentially, knowing that at least one of them is true raises the probability
of
each. But further knowledge that ``w`` is true (or false) change the
conditional
probability of ``u`` to either the original value or 1. So the conditional
probability of ``u`` depends on the outcome of ``w`` even though there is no
causal relationship between them. When a collider is known, dependence can
occur across paths through that collider. This is the reason open colliders
do not block paths.
Furthermore, even if ``v`` is not "known", if one of its descendants is
"known"
we can use that information to know more about ``v`` which again makes
``u`` and ``w`` potentially dependent. Suppose the chance of ``n`` occurring
is much higher when ``v`` occurs ("at least one of ``u`` and ``w`` occur").
Then if we know ``n`` occurred, it is more likely that ``v`` occurred and that
makes the chance of ``u`` and ``w`` dependent. This is the idea behind why
a collider does no block a path if any descendant of the collider is "known".
When two sets of nodes ``x`` and ``y`` are d-separated by a set ``z``,
it means that given the outcomes of the nodes in ``z``, the probabilities
of outcomes of the nodes in ``x`` are independent of the outcomes of the
nodes in ``y`` and vice versa.
Examples
--------
A Hidden Markov Model with 5 observed states and 5 hidden states
where the hidden states have causal relationships resulting in
a path results in the following causal network. We check that
early states along the path are separated from late state in
the path by the d-separator of the middle hidden state.
Thus if we condition on the middle hidden state, the early
state probabilities are independent of the late state outcomes.

(0)             def find_minimal_d_separator(G, x, y, *, included=None, restricted=None):
(4)                 """Returns a minimal d-separating set between `x` and `y` if possible
(4)                 A d-separating set in a DAG is a set of nodes that blocks all
(4)                 paths between the two sets of nodes, `x` and `y`. This function
(4)                 constructs a d-separating set that is "minimal", meaning no nodes can
(4)                 be removed without it losing the d-separating property for `x` and `y`.
(4)                 If no d-separating sets exist for `x` and `y`, this returns `None`.
(4)                 In a DAG there may be more than one minimal d-separator between two
(4)                 sets of nodes. Minimal d-separators are not always unique. This function
(4)                 returns one minimal d-separator, or `None` if no d-separator exists.
(4)                 Uses the algorithm presented in [1]_. The complexity of the algorithm
(4)                 is :math:`O(m)`, where :math:`m` stands for the number of edges in
(4)                 the subgraph of G consisting of only the ancestors of `x` and `y`.
(4)                 For full details, see [1]_.
(4)                 Parameters
```

```
    ----------
    G : graph
        A networkx DAG.
    x : set | node
        A node or set of nodes in the graph.
    y : set | node
        A node or set of nodes in the graph.
    included : set | node | None
        A node or set of nodes which must be included in the found separating set,
        default is None, which means the empty set.
    restricted : set | node | None
        Restricted node or set of nodes to consider. Only these nodes can be in
        the found separating set, default is None meaning all nodes in ``G``.
    Returns
    -------
    z : set | None
        The minimal d-separating set, if at least one d-separating set exists,
        otherwise None.
    Raises
    ------
    NetworkXError
        Raises a :exc:`NetworkXError` if the input graph is not a DAG
        or if node sets `x`, `y`, and `included` are not disjoint.
    NodeNotFound
        If any of the input nodes are not found in the graph,
        a :exc:`NodeNotFound` exception is raised.

def is_minimal_d_separator(G, x, y, z, *, included=None, restricted=None):
    """Determine if `z` is a minimal d-separator for `x` and `y`.
    A d-separator, `z`, in a DAG is a set of nodes that blocks
    all paths from nodes in set `x` to nodes in set `y`.
    A minimal d-separator is a d-separator `z` such that removing
    any subset of nodes makes it no longer a d-separator.
    Note: This function checks whether `z` is a d-separator AND is
    minimal. One can use the function `is_d_separator` to only check if
    `z` is a d-separator. See examples below.
    Parameters
    ----------
    G : nx.DiGraph
        A NetworkX DAG.
    x : node | set
        A node or set of nodes in the graph.
    y : node | set
        A node or set of nodes in the graph.
    z : node | set
        The node or set of nodes to check if it is a minimal d-separating set.
        The function :func:`is_d_separator` is called inside this function
        to verify that `z` is in fact a d-separator.
    included : set | node | None
        A node or set of nodes which must be included in the found separating set,
        default is ``None``, which means the empty set.
    restricted : set | node | None
        Restricted node or set of nodes to consider. Only these nodes can be in
        the found separating set, default is ``None`` meaning all nodes in ``G``.
    Returns
    -------
    bool
        Whether or not the set `z` is a minimal d-separator subject to
        `restricted` nodes and `included` node constraints.
    Examples
    --------
    >>> G = nx.path_graph([0, 1, 2, 3], create_using=nx.DiGraph)
    >>> G.add_node(4)
    >>> nx.is_minimal_d_separator(G, 0, 2, {1})
    True
    >>> # since {1} is the minimal d-separator, {1, 3, 4} is not minimal
    >>> nx.is_minimal_d_separator(G, 0, 2, {1, 3, 4})
    False
    >>> # alternatively, if we only want to check that {1, 3, 4} is a d-separator
    >>> nx.is_d_separator(G, 0, 2, {1, 3, 4})
    True
    Raises
    ------
    NetworkXError
        Raises a :exc:`NetworkXError` if the input graph is not a DAG.
    NodeNotFound
        If any of the input nodes are not found in the graph,
        a :exc:`NodeNotFound` exception is raised.

```

```
    Find all nodes in `a` that are d-connected to those in `x` by
    those in `z`. This is an implementation of the function
    `REACHABLE` in [1]_ (which is itself a modification of the
    Bayes-Ball algorithm [2]_) when restricted to DAGs.
    Parameters
    ----------
    G : nx.DiGraph
        A NetworkX DAG.
    x : node | set
        A node in the DAG, or a set of nodes.
    a : node | set
        A (set of) node(s) in the DAG containing the ancestors of `x`.
    z : node | set
        The node or set of nodes conditioned on when checking d-connectedness.
    Returns
    -------
    w : set
        The closure of `x` in `a` with respect to d-connectedness
        given `z`.
    References

194: (4)                A topological sort is a nonunique permutation of the nodes of a
195: (4)                directed graph such that an edge from u to v implies that u
196: (4)                appears before v in the topological sort order. This ordering is
197: (4)                valid only if the graph has no directed cycles.
198: (4)                Parameters
199: (4)                ----------
200: (4)                G : NetworkX digraph
201: (8)                    A directed acyclic graph (DAG)
202: (4)                Yields
203: (4)                ------
204: (4)                nodes
205: (8)                    Yields the nodes in topological sorted order.
206: (4)                Raises
207: (4)                ------
208: (4)                NetworkXError
209: (8)                    Topological sort is defined for directed graphs only. If the graph `G`
210: (8)                    is undirected, a :exc:`NetworkXError` is raised.
211: (4)                NetworkXUnfeasible
212: (8)                    If `G` is not a directed acyclic graph (DAG) no topological sort
exists
213: (8)                    and a :exc:`NetworkXUnfeasible` exception is raised.  This can also be
214: (8)                    raised if `G` is changed while the returned iterator is being
processed
215: (4)                RuntimeError
216: (8)                    If `G` is changed while the returned iterator is being processed.
```

```
217: (4)                Examples
218: (4)                --------
219: (4)                To get the reverse order of the topological sort:
220: (4)                >>> DG = nx.DiGraph([(1, 2), (2, 3)])
221: (4)                >>> list(reversed(list(nx.topological_sort(DG))))
222: (4)                [3, 2, 1]
223: (4)                If your DiGraph naturally has the edges representing tasks/inputs
224: (4)                and nodes representing people/processes that initiate tasks, then
225: (4)                topological_sort is not quite what you need. You will have to change
226: (4)                the tasks to nodes with dependence reflected by edges. The result is
227: (4)                a kind of topological sort of the edges. This can be done
228: (4)                with :func:`networkx.line_graph` as follows:
229: (4)                >>> list(nx.topological_sort(nx.line_graph(DG)))
230: (4)                [(1, 2), (2, 3)]

242: (4)                """
243: (4)                for generation in nx.topological_generations(G):
244: (8)                    yield from generation
245: (0)            @nx._dispatchable
246: (0)            def lexicographical_topological_sort(G, key=None):
247: (4)                """Generate the nodes in the unique lexicographical topological sort
order.
248: (4)                Generates a unique ordering of nodes by first sorting topologically (for
which there are often
249: (4)                multiple valid orderings) and then additionally by sorting
lexicographically.
250: (4)                A topological sort arranges the nodes of a directed graph so that the
251: (4)                upstream node of each directed edge precedes the downstream node.
252: (4)                It is always possible to find a solution for directed graphs that have no
cycles.
253: (4)                There may be more than one valid solution.
254: (4)                Lexicographical sorting is just sorting alphabetically. It is used here to
break ties in the
255: (4)                topological sort and to determine a single, unique ordering.  This can be
useful in comparing
256: (4)                sort results.
257: (4)                The lexicographical order can be customized by providing a function to the
`key=` parameter.
258: (4)                The definition of the key function is the same as used in python's built-
in `sort()`.
259: (4)                The function takes a single argument and returns a key to use for sorting
purposes.
260: (4)                Lexicographical sorting can fail if the node names are un-sortable. See
the example below.
261: (4)                The solution is to provide a function to the `key=` argument that returns
sortable keys.
262: (4)                Parameters
263: (4)                ----------
264: (4)                G : NetworkX digraph
265: (8)                    A directed acyclic graph (DAG)
266: (4)                key : function, optional
267: (8)                    A function of one argument that converts a node name to a comparison
key.
268: (8)                    It defines and resolves ambiguities in the sort order.  Defaults to
the identity function.
269: (4)                Yields
270: (4)                ------
271: (4)                nodes
272: (8)                    Yields the nodes of G in lexicographical topological sort order.
```

```
    Raises
    ------
    NetworkXError
        Topological sort is defined for directed graphs only. If the graph `G`
        is undirected, a :exc:`NetworkXError` is raised.
    NetworkXUnfeasible
        If `G` is not a directed acyclic graph (DAG) no topological sort exists
        and a :exc:`NetworkXUnfeasible` exception is raised.  This can also be
        raised if `G` is changed while the returned iterator is being processed
    RuntimeError
        If `G` is changed while the returned iterator is being processed.
    TypeError
        Results from un-sortable node names.
        Consider using `key=` parameter to resolve ambiguities in the sort order.
    Examples
    --------
    >>> DG = nx.DiGraph([(2, 1), (2, 5), (1, 3), (1, 4), (5, 4)])
    >>> list(nx.lexicographical_topological_sort(DG))
    [2, 1, 3, 5, 4]
    >>> list(nx.lexicographical_topological_sort(DG, key=lambda x: -x))
    [2, 5, 1, 4, 3]
    The sort will fail for any graph with integer and string nodes. Comparison of integer to strings
    is not defined in python.  Is 3 greater or less than 'red'?
    >>> DG = nx.DiGraph([(1, "red"), (3, "red"), (1, "green"), (2, "blue")])
    >>> list(nx.lexicographical_topological_sort(DG))
    Traceback (most recent call last):
    ...
    TypeError: '<' not supported between instances of 'str' and 'int'
    ...
    Incomparable nodes can be resolved using a `key` function. This example function
    allows comparison of integers and strings by returning a tuple where the first
    element is True for `str`, False otherwise. The second element is the node name.
    This groups the strings and integers separately so they can be compared only among themselves.
    >>> key = lambda node: (isinstance(node, str), node)
    >>> list(nx.lexicographical_topological_sort(DG, key=key))
    [1, 2, 3, 'blue', 'green', 'red']

(4)                 """Returns True if `G` is aperiodic.
(4)                 A directed graph is aperiodic if there is no integer k > 1 that
(4)                 divides the length of every cycle in the graph.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX DiGraph
(8)                     A directed graph
(4)                 Returns
(4)                 -------
(4)                 bool
(8)                     True if the graph is aperiodic False otherwise
(4)                 Raises
(4)                 ------
(4)                 NetworkXError
(8)                     If `G` is not directed
(4)                 Examples
(4)                 --------
(4)                 A graph consisting of one cycle, the length of which is 2. Therefore ``k =
2``
(4)                 divides the length of every cycle in the graph and thus the graph
(4)                 is *not aperiodic*::
(8)                     >>> DG = nx.DiGraph([(1, 2), (2, 1)])
(8)                     >>> nx.is_aperiodic(DG)
(8)                     False
(4)                 A graph consisting of two cycles: one of length 2 and the other of length
3.
(4)                 The cycle lengths are coprime, so there is no single value of k where ``k
> 1``
(4)                 that divides each cycle length and therefore the graph is *aperiodic*::
(8)                     >>> DG = nx.DiGraph([(1, 2), (2, 3), (3, 1), (1, 4), (4, 1)])
(8)                     >>> nx.is_aperiodic(DG)
(8)                     True
(4)                 A graph consisting of two cycles: one of length 2 and the other of length
4.
(4)                 The lengths of the cycles share a common factor ``k = 2``, and therefore
(4)                 the graph is *not aperiodic*::
(8)                     >>> DG = nx.DiGraph([(1, 2), (2, 1), (3, 4), (4, 5), (5, 6), (6, 3)])
```

```
465: (8)                >>> nx.is_aperiodic(DG)
466: (8)                False
467: (4)            An acyclic graph, therefore the graph is *not aperiodic*::
468: (8)                >>> DG = nx.DiGraph([(1, 2), (2, 3)])
469: (8)                >>> nx.is_aperiodic(DG)
470: (8)                False
471: (4)            Notes
472: (4)            -----
473: (4)            This uses the method outlined in [1]_, which runs in $O(m)$ time
474: (4)            given $m$ edges in `G`. Note that a graph is not aperiodic if it is
475: (4)            acyclic as every integer trivial divides length 0 cycles.

508: (0)        def transitive_closure(G, reflexive=False):
509: (4)            """Returns transitive closure of a graph
510: (4)            The transitive closure of G = (V,E) is a graph G+ = (V,E+) such that
511: (4)            for all v, w in V there is an edge (v, w) in E+ if and only if there
512: (4)            is a path from v to w in G.
513: (4)            Handling of paths from v to v has some flexibility within this definition.
514: (4)            A reflexive transitive closure creates a self-loop for the path
515: (4)            from v to v of length 0. The usual transitive closure creates a
516: (4)            self-loop only if a cycle exists (a path from v to v with length > 0).
517: (4)            We also allow an option for no self-loops.
518: (4)            Parameters
519: (4)            ----------
520: (4)            G : NetworkX Graph
521: (8)                A directed/undirected graph/multigraph.
522: (4)            reflexive : Bool or None, optional (default: False)
523: (8)                Determines when cycles create self-loops in the Transitive Closure.
524: (8)                If True, trivial cycles (length 0) create self-loops. The result
525: (8)                is a reflexive transitive closure of G.
526: (8)                If False (the default) non-trivial cycles create self-loops.
527: (8)                If None, self-loops are not created.
528: (4)            Returns
529: (4)            -------
530: (4)            NetworkX graph
531: (8)                The transitive closure of `G`
532: (4)            Raises
```

```
    ------
    NetworkXError
        If `reflexive` not in `{None, True, False}`
    Examples
    --------
    The treatment of trivial (i.e. length 0) cycles is controlled by the
    `reflexive` parameter.
    Trivial (i.e. length 0) cycles do not create self-loops when
    ``reflexive=False`` (the default)::
        >>> DG = nx.DiGraph([(1, 2), (2, 3)])
        >>> TC = nx.transitive_closure(DG, reflexive=False)
        >>> TC.edges()
        OutEdgeView([(1, 2), (1, 3), (2, 3)])
    However, nontrivial (i.e. length greater than 0) cycles create self-loops
    when ``reflexive=False`` (the default)::
        >>> DG = nx.DiGraph([(1, 2), (2, 3), (3, 1)])
        >>> TC = nx.transitive_closure(DG, reflexive=False)
        >>> TC.edges()
        OutEdgeView([(1, 2), (1, 3), (1, 1), (2, 3), (2, 1), (2, 2), (3, 1), (3, 2), (3, 3)])
    Trivial cycles (length 0) create self-loops when ``reflexive=True``::
        >>> DG = nx.DiGraph([(1, 2), (2, 3)])
        >>> TC = nx.transitive_closure(DG, reflexive=True)
        >>> TC.edges()
        OutEdgeView([(1, 2), (1, 1), (1, 3), (2, 3), (2, 2), (3, 3)])
    And the third option is not to create self-loops at all when ``reflexive=None``::
        >>> DG = nx.DiGraph([(1, 2), (2, 3), (3, 1)])
        >>> TC = nx.transitive_closure(DG, reflexive=None)
        >>> TC.edges()
        OutEdgeView([(1, 2), (1, 3), (2, 3), (2, 1), (3, 1), (3, 2)])

    """Returns the transitive closure of a directed acyclic graph.
    This function is faster than the function `transitive_closure`, but fails
    if the graph has a cycle.
    The transitive closure of G = (V,E) is a graph G+ = (V,E+) such that
    for all v, w in V there is an edge (v, w) in E+ if and only if there
    is a non-null path from v to w in G.
    Parameters
    ----------
    G : NetworkX DiGraph
        A directed acyclic graph (DAG)
    topo_order: list or tuple, optional
        A topological order for G (if None, the function will compute one)
    Returns
    -------
    NetworkX DiGraph
```

```
(8)                 The transitive closure of `G`
(4)             Raises
(4)             ------
(4)             NetworkXNotImplemented
(8)                 If `G` is not directed
(4)             NetworkXUnfeasible
(8)                 If `G` has a cycle
(4)             Examples
(4)             --------
(4)             >>> DG = nx.DiGraph([(1, 2), (2, 3)])
(4)             >>> TC = nx.transitive_closure_dag(DG)
(4)             >>> TC.edges()
(4)             OutEdgeView([(1, 2), (1, 3), (2, 3)])
(4)             Notes
(4)             -----
(4)             This algorithm is probably simple enough to be well-known but I didn't find
(4)             a mention in the literature.
(4)             """

```

```
(0)  def dag_to_branching(G):
(4)      """Returns a branching representing all (overlapping) paths from
(4)      root nodes to leaf nodes in the given directed acyclic graph.
(4)      As described in :mod:`networkx.algorithms.tree.recognition`, a
(4)      *branching* is a directed forest in which each node has at most one
(4)      parent. In other words, a branching is a disjoint union of
(4)      *arborescences*. For this function, each node of in-degree zero in
(4)      `G` becomes a root of one of the arborescences, and there will be
(4)      one leaf node for each distinct path from that root to a leaf node
(4)      in `G`.
(4)      Each node `v` in `G` with *k* parents becomes *k* distinct nodes in
(4)      the returned branching, one for each parent, and the sub-DAG rooted
(4)      at `v` is duplicated for each copy. The algorithm then recurses on
(4)      the children of each copy of `v`.
(4)      Parameters
(4)      ----------
(4)      G : NetworkX graph
(8)          A directed acyclic graph.
(4)      Returns
(4)      -------
(4)      DiGraph
(8)          The branching in which there is a bijection between root-to-leaf
(8)          paths in `G` (in which multiple paths may share the same leaf)
(8)          and root-to-leaf paths in the branching (in which there is a
(8)          unique path from a root to a leaf).
(8)          Each node has an attribute 'source' whose value is the original
(8)          node to which this node corresponds. No other graph, node, or
(8)          edge attributes are copied into this new graph.
(4)      Raises
(4)      ------
(4)      NetworkXNotImplemented
(8)          If `G` is not directed, or if `G` is a multigraph.
(4)      HasACycle
(8)          If `G` is not acyclic.
(4)      Examples
(4)      --------
(4)      To examine which nodes in the returned branching were produced by
(4)      which original node in the directed acyclic graph, we can collect
(4)      the mapping from source node to new nodes into a dictionary. For
(4)      example, consider the directed diamond graph::
(8)          >>> from collections import defaultdict
(8)          >>> from operator import itemgetter
(8)          >>>
(8)          >>> G = nx.DiGraph(nx.utils.pairwise("abd"))
(8)          >>> G.add_edges_from(nx.utils.pairwise("acd"))
(8)          >>> B = nx.dag_to_branching(G)
(8)          >>>
(8)          >>> sources = defaultdict(set)
(8)          >>> for v, source in B.nodes(data="source"):
(8)          ...     sources[source].add(v)
(8)          >>> len(sources["a"])
(8)          1
(8)          >>> len(sources["d"])
(8)          2
(4)      To copy node attributes from the original graph to the new graph,
(4)      you can use a dictionary like the one constructed in the above
(4)      example::
(8)          >>> for source, nodes in sources.items():
(8)          ...     for v in nodes:
(8)          ...         B.nodes[v].update(G.nodes[source])
(4)      Notes
(4)      -----
(4)      This function is not idempotent in the sense that the node labels in
(4)      the returned branching may be uniquely generated each time the
(4)      function is invoked. In fact, the node labels may not be integers;
(4)      in order to relabel the nodes to be more readable, you can use the
(4)      :func:`networkx.convert_node_labels_to_integers` function.
(4)      The current implementation of this function uses
(4)      :func:`networkx.prefix_tree`, so it is subject to the limitations of
```

```
934: (4)                that function.

18: (4)                 linear in the number of nodes, rather than quadratic (except for some
19: (4)                 border cases such as complete graphs or circle shaped graphs).
20: (4)                 Parameters
21: (4)                 ----------
```

```
22: (4)                 G : NetworkX graph
23: (7)                    An undirected graph
24: (4)                 compute : string denoting the requesting metric
25: (7)                    "diameter" for the maximal eccentricity value,
26: (7)                    "radius" for the minimal eccentricity value,
27: (7)                    "periphery" for the set of nodes with eccentricity equal to the
diameter,
28: (7)                    "center" for the set of nodes with eccentricity equal to the radius,
29: (7)                    "eccentricities" for the maximum distance from each node to all other
nodes in G
30: (4)                 weight : string, function, or None
31: (8)                     If this is a string, then edge weights will be accessed via the
32: (8)                     edge attribute with this key (that is, the weight of the edge
33: (8)                     joining `u` to `v` will be ``G.edges[u, v][weight]``). If no
34: (8)                     such edge attribute exists, the weight of the edge is assumed to
35: (8)                     be one.
36: (8)                     If this is a function, the weight of an edge is the value
37: (8)                     returned by the function. The function must accept exactly three
38: (8)                     positional arguments: the two endpoints of an edge and the
39: (8)                     dictionary of edge attributes for that edge. The function must
40: (8)                     return a number.
41: (8)                     If this is None, every edge has weight/distance/cost 1.
42: (8)                     Weights stored as floating point values can lead to small round-off
43: (8)                     errors in distances. Use integer weights to avoid this.
44: (8)                     Weights should be positive, since they are distances.
45: (4)                 Returns
46: (4)                 -------
47: (4)                 value : value of the requested metric
48: (7)                    int for "diameter" and "radius" or
49: (7)                    list of nodes for "center" and "periphery" or
50: (7)                    dictionary of eccentricity values keyed by node for "eccentricities"
51: (4)                 Raises
52: (4)                 ------
53: (4)                 NetworkXError
54: (8)                     If the graph consists of multiple components
55: (4)                 ValueError
56: (8)                     If `compute` is not one of "diameter", "radius", "periphery",
"center", or "eccentricities".

422: (4)                <networkx.algorithms.shortest_paths.generic.shortest_path_length>`.
```

```
    The barycenter is also called the :dfn:`median`. See [West01]_, p. 78.
    Parameters
    ----------
    G : :class:`networkx.Graph`
        The connected graph :math:`G`.
    weight : :class:`str`, optional
        Passed through to
:func:`~networkx.algorithms.shortest_paths.generic.shortest_path_length`.
    attr : :class:`str`, optional
        If given, write the value of the objective function to each node's
        `attr` attribute. Otherwise do not store the value.
    sp : dict of dicts, optional
       All pairs shortest path lengths as a dictionary of dictionaries
    Returns
    -------
    list
        Nodes of `G` that induce the barycenter of `G`.
    Raises
    ------
    NetworkXNoPath
        If `G` is disconnected. `G` may appear disconnected to
        :func:`barycenter` if `sp` is given but is missing shortest path
        lengths for any pairs.
    ValueError
        If `sp` and `weight` are both given.
    Examples
    --------
    >>> G = nx.Graph([(1, 2), (1, 3), (1, 4), (3, 4), (3, 5), (4, 5)])
    >>> nx.barycenter(G)
    [1, 3, 4]

invert_weight=True):
    """Returns the resistance distance between pairs of nodes in graph G.
    The resistance distance between two nodes of a graph is akin to treating
    the graph as a grid of resistors with a resistance equal to the provided
    weight [1]_, [2]_.
    If weight is not provided, then a weight of 1 is used for all edges.
```

```
    If two nodes are the same, the resistance distance is zero.
    Parameters
    ----------
    G : NetworkX graph
       A graph
    nodeA : node or None, optional (default=None)
      A node within graph G.
      If None, compute resistance distance using all nodes as source nodes.
    nodeB : node or None, optional (default=None)
      A node within graph G.
      If None, compute resistance distance using all nodes as target nodes.
    weight : string or None, optional (default=None)
       The edge data key used to compute the resistance distance.
       If None, then each edge has weight 1.
    invert_weight : boolean (default=True)
        Proper calculation of resistance distance requires building the
        Laplacian matrix with the reciprocal of the weight. Not required
        if the weight is already inverted. Weight cannot be zero.
    Returns
    -------
    rd : dict or float
       If `nodeA` and `nodeB` are given, resistance distance between `nodeA`
       and `nodeB`. If `nodeA` or `nodeB` is unspecified (the default), a
       dictionary of nodes with resistance distances as the value.
    Raises
    ------
    NetworkXNotImplemented
        If `G` is a directed graph.
    NetworkXError
        If `G` is not connected, or contains no nodes,
        or `nodeA` is not in `G` or `nodeB` is not in `G`.
    Examples
    --------
    >>> G = nx.Graph([(1, 2), (1, 3), (1, 4), (3, 4), (3, 5), (4, 5)])
    >>> round(nx.resistance_distance(G, 1, 3), 10)
    0.625
    Notes
    -----
    The implementation is based on Theorem A in [2]_. Self-loops are ignored.
    Multi-edges are contracted in one edge with weight equal to the harmonic sum of the weights.

    -------
    float
        The Kemeny constant of the graph `G`.
    Raises
    ------
    NetworkXNotImplemented
        If the graph `G` is directed.
    NetworkXError
        If the graph `G` is not connected, or contains no nodes,
        or has edges with negative weights.
    Examples
    --------
    >>> G = nx.complete_graph(5)
    >>> round(nx.kemeny_constant(G), 10)
```

(0)         def has_eulerian_path(G, source=None):
(4)             """Return True iff `G` has an Eulerian path.
(4)             An Eulerian path is a path in a graph which uses each edge of a graph
(4)             exactly once. If `source` is specified, then this function checks
(4)             whether an Eulerian path that starts at node `source` exists.
(4)             A directed graph has an Eulerian path iff:
(8)                 - at most one vertex has out_degree - in_degree = 1,
(8)                 - at most one vertex has in_degree - out_degree = 1,
(8)                 - every other vertex has equal in_degree and out_degree,
(8)                 - and all of its vertices belong to a single connected
(10)                  component of the underlying undirected graph.
(4)             If `source` is not None, an Eulerian path starting at `source` exists if
no
(4)             other node has out_degree - in_degree = 1. This is equivalent to either
(4)             there exists an Eulerian circuit or `source` has out_degree - in_degree =
1
(4)             and the conditions above hold.
(4)             An undirected graph has an Eulerian path iff:
(8)                 - exactly zero or two vertices have odd degree,
(8)                 - and all of its vertices belong to a single connected component.
(4)             If `source` is not None, an Eulerian path starting at `source` exists if
(4)             either there exists an Eulerian circuit or `source` has an odd degree and
```

```
the
(4)                 conditions above hold.
(4)                 Graphs with isolated vertices (i.e. vertices with zero degree) are not
considered
(4)                 to have an Eulerian path. Therefore, if the graph is not connected (or not
strongly
(4)                 connected, for directed graphs), this function returns False.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX Graph
(8)                     The graph to find an euler path in.
(4)                 source : node, optional
(8)                     Starting node for path.
(4)                 Returns
(4)                 -------
(4)                 Bool : True if G has an Eulerian path.
(4)                 Examples
(4)                 --------
(4)                 If you prefer to allow graphs with isolated vertices to have Eulerian
path,
(4)                 you can first remove such vertices and then call `has_eulerian_path` as
below example shows.
(4)                 >>> G = nx.Graph([(0, 1), (1, 2), (0, 2)])

137: (4)                """
138: (4)                Return a dictionary of subgraph hashes by node.
139: (4)                Dictionary keys are nodes in `G`, and values are a list of hashes.
140: (4)                Each hash corresponds to a subgraph rooted at a given node u in `G`.
141: (4)                Lists of subgraph hashes are sorted in increasing order of depth from
142: (4)                their root node, with the hash at index i corresponding to a subgraph
143: (4)                of nodes at most i edges distance from u. Thus, each list will contain
144: (4)                `iterations` elements - a hash for a subgraph at each depth. If
145: (4)                `include_initial_labels` is set to `True`, each list will additionally
146: (4)                have contain a hash of the initial node label (or equivalently a
147: (4)                subgraph of depth 0) prepended, totalling ``iterations + 1`` elements.
148: (4)                The function iteratively aggregates and hashes neighborhoods of each node.
149: (4)                This is achieved for each step by replacing for each node its label from
150: (4)                the previous iteration with its hashed 1-hop neighborhood aggregate.
151: (4)                The new node label is then appended to a list of node labels for each
152: (4)                node.
153: (4)                To aggregate neighborhoods for a node $u$ at each step, all labels of
154: (4)                nodes adjacent to $u$ are concatenated. If the `edge_attr` parameter is
set,
155: (4)                labels for each neighboring node are prefixed with the value of this
attribute
156: (4)                along the connecting edge from this neighbor to node $u$. The resulting
string
157: (4)                is then hashed to compress this information into a fixed digest size.
158: (4)                Thus, at the $i$-th iteration, nodes within $i$ hops influence any given
```

```
hashed node label. We can therefore say that at depth $i$ for node $u$
we have a hash for a subgraph induced by the $i$-hop neighborhood of $u$.
The output can be used to to create general Weisfeiler-Lehman graph kernels,
or generate features for graphs or nodes - for example to generate 'words' in
a graph as seen in the 'graph2vec' algorithm.
See [1]_ & [2]_ respectively for details.
Hashes are identical for isomorphic subgraphs and there exist strong
guarantees that non-isomorphic graphs will get different hashes.
See [1]_ for details.
If no node or edge attributes are provided, the degree of each node
is used as its initial label.
Otherwise, node and/or edge labels are used to compute the hash.
Parameters
----------
G : graph
    The graph to be hashed.
    Can have node and/or edge attributes. Can also have no attributes.
edge_attr : string, optional (default=None)
    The key in edge attribute dictionary to be used for hashing.
    If None, edge labels are ignored.
node_attr : string, optional (default=None)
    The key in node attribute dictionary to be used for hashing.
    If None, and no edge_attr given, use the degrees of the nodes as labels.

    If None, and edge_attr is given, each node starts with an identical label.
iterations : int, optional (default=3)
    Number of neighbor aggregations to perform.
    Should be larger for larger graphs.
digest_size : int, optional (default=16)
    Size (in bits) of blake2b hash digest to use for hashing node labels.
    The default size is 16 bits.
include_initial_labels : bool, optional (default=False)
    If True, include the hashed initial node label as the first subgraph
    hash for each node.
Returns
-------
node_subgraph_hashes : dict
    A dictionary with each key given by a node in G, and each value given
    by the subgraph hashes in order of depth from the key node.
Examples
--------
Finding similar nodes in different graphs:
>>> G1 = nx.Graph()
>>> G1.add_edges_from([(1, 2), (2, 3), (2, 4), (3, 5), (4, 6), (5, 7), (6, 7)])
>>> G2 = nx.Graph()
>>> G2.add_edges_from([(1, 3), (2, 3), (1, 6), (1, 5), (4, 6)])
>>> g1_hashes = nx.weisfeiler_lehman_subgraph_hashes(G1, iterations=3, digest_size=8)
>>> g2_hashes = nx.weisfeiler_lehman_subgraph_hashes(G2, iterations=3, digest_size=8)
Even though G1 and G2 are not isomorphic (they have different numbers of edges),
the hash sequence of depth 3 for node 1 in G1 and node 5 in G2 are similar:
>>> g1_hashes[1]
['a93b64973cfc8897', 'db1b43ae35a1878f', '57872a7d2059c1c0']
>>> g2_hashes[5]
['a93b64973cfc8897', 'db1b43ae35a1878f', '1716d2a4012fa4bc']
The first 2 WL subgraph hashes match. From this we can conclude that it's very
likely the neighborhood of 2 hops around these nodes are isomorphic.
However the 3-hop neighborhoods of ``G1`` and ``G2`` are not isomorphic since the
3rd hashes in the lists above are not equal.
These nodes may be candidates to be classified together since their local

def common_neighbor_centrality(G, ebunch=None, alpha=0.8):
    r"""Return the CCPA score for each pair of nodes.
    Compute the Common Neighbor and Centrality based Parameterized Algorithm(CCPA)
    score of all node pairs in ebunch.
    CCPA score of `u` and `v` is defined as
    .. math::
        \alpha \cdot (|\Gamma (u){\cap }^{}\Gamma (v)|)+(1-\alpha )\cdot \frac{N}{{d}_{uv}}
    where $\Gamma(u)$ denotes the set of neighbors of $u$, $\Gamma(v)$ denotes the
    set of neighbors of $v$, $\alpha$ is  parameter varies between [0,1], $N$ denotes
    total number of nodes in the Graph and ${d}_{uv}$ denotes shortest distance
    between $u$ and $v$.
    This algorithm is based on two vital properties of nodes, namely the number
    of common neighbors and their centrality. Common neighbor refers to the common
    nodes between two nodes. Centrality refers to the prestige that a node enjoys
    in a network.
    .. seealso::
        :func:`common_neighbors`
    Parameters
    ----------
    G : graph
        NetworkX undirected graph.
    ebunch : iterable of node pairs, optional (default = None)
        Preferential attachment score will be computed for each pair of
        nodes given in the iterable. The pairs must be given as
```

```
(8)                 2-tuples (u, v) where u and v are nodes in the graph. If ebunch
(8)                 is None then all nonexistent edges in the graph will be used.
(8)                 Default value: None.
(4)             alpha : Parameter defined for participation of Common Neighbor
(12)                    and Centrality Algorithm share. Values for alpha should
(12)                    normally be between 0 and 1. Default value set to 0.8
(12)                    because author found better performance at 0.8 for all the
(12)                    dataset.
(12)                    Default value: 0.8

(4)                 r"""Compute the resource allocation index of all node pairs in
(4)                 ebunch using community information.
(4)                 For two nodes $u$ and $v$, this function computes the resource
(4)                 allocation index considering only common neighbors belonging to the
(4)                 same community as $u$ and $v$. Mathematically,
(4)                 .. math::
(8)                     \sum_{w \in \Gamma(u) \cap \Gamma(v)} \frac{f(w)}{|\Gamma(w)|}
(4)                 where $f(w)$ equals 1 if $w$ belongs to the same community as $u$
(4)                 and $v$ or 0 otherwise and $\Gamma(u)$ denotes the set of
(4)                 neighbors of $u$.
(4)                 Parameters
(4)                 ----------
(4)                 G : graph
(8)                     A NetworkX undirected graph.
(4)                 ebunch : iterable of node pairs, optional (default = None)
(8)                     The score will be computed for each pair of nodes given in the
(8)                     iterable. The pairs must be given as 2-tuples (u, v) where u
(8)                     and v are nodes in the graph. If ebunch is None then all
(8)                     nonexistent edges in the graph will be used.
(8)                     Default value: None.
(4)                 community : string, optional (default = 'community')
(8)                     Nodes attribute name containing the community information.
(8)                     G[u][community] identifies which community u belongs to. Each
(8)                     node belongs to at most one community. Default value: 'community'.
(4)                 Returns
(4)                 -------
(4)                 piter : iterator
(8)                     An iterator of 3-tuples in the form (u, v, p) where (u, v) is a
```

```
(8)                     pair of nodes and p is their score.
(4)                 Raises

122: (4)                Parameters
123: (4)                ----------
124: (4)                G : NetworkX directed graph (must be a tree)
125: (4)                root : node, optional (default: None)
126: (8)                    The root of the subtree to operate on.
127: (8)                    If None, assume the entire graph has exactly one source and use that.
128: (4)                pairs : iterable or iterator of pairs of nodes, optional (default: None)
129: (8)                    The pairs of interest. If None, Defaults to all pairs of nodes
130: (8)                    under `root` that have a lowest common ancestor.
131: (4)                Returns
132: (4)                -------
133: (4)                lcas : generator of tuples `((u, v), lca)` where `u` and `v` are nodes
134: (8)                    in `pairs` and `lca` is their lowest common ancestor.
135: (4)                Examples
136: (4)                --------
137: (4)                >>> import pprint
```

```
    >>> G = nx.DiGraph([(1, 3), (2, 4), (1, 2)])
    >>> pprint.pprint(dict(nx.tree_all_pairs_lowest_common_ancestor(G)))
    {(1, 1): 1,
     (2, 1): 1,
     (2, 2): 2,
     (3, 1): 1,
     (3, 2): 1,
     (3, 3): 3,
     (3, 4): 1,
     (4, 1): 1,
     (4, 2): 2,
     (4, 4): 4}
    We can also use `pairs` argument to specify the pairs of nodes for which we
    want to compute lowest common ancestors. Here is an example:
    >>> dict(nx.tree_all_pairs_lowest_common_ancestor(G, pairs=[(1, 4), (2, 3)]))
    {(2, 3): 1, (1, 4): 1}
    Notes
    -----
    Only defined on non-null trees represented with directed edges from
    parents to children. Uses Tarjan's off-line lowest-common-ancestors
    algorithm. Runs in time $O(4 \times (V + E + P))$ time, where 4 is the largest
    value of the inverse Ackermann function likely to ever come up in actual
    use, and $P$ is the number of pairs requested (or $V^2$ if all are needed).
    Tarjan, R. E. (1979), "Applications of path compression on balanced trees",
    Journal of the ACM 26 (4): 690-715, doi:10.1145/322154.322161.

 122: (4)                   Parameters
```

```
    ----------
    G : NetworkX graph
    matching : dict or set
        A dictionary or set representing a matching. If a dictionary, it
        must have ``matching[u] == v`` and ``matching[v] == u`` for each
        edge ``(u, v)`` in the matching. If a set, it must have elements
        of the form ``(u, v)``, where ``(u, v)`` is an edge in the
        matching.
    Returns
    -------
    bool
        Whether the given set or dictionary represents a valid maximal
        matching in the graph.
    Examples
    --------
    >>> G = nx.Graph([(1, 2), (1, 3), (2, 3), (3, 4), (3, 5)])
    >>> nx.is_maximal_matching(G, {(1, 2), (3, 4)})

209: (0)            @not_implemented_for("multigraph")
210: (0)            @not_implemented_for("directed")
211: (0)            @nx._dispatchable(edge_attrs="weight")
212: (0)            def min_weight_matching(G, weight="weight"):
213: (4)                """Computing a minimum-weight maximal matching of G.
214: (4)                Use the maximum-weight algorithm with edge weights subtracted
215: (4)                from the maximum weight of all edges.
216: (4)                A matching is a subset of edges in which no node occurs more than once.
217: (4)                The weight of a matching is the sum of the weights of its edges.
218: (4)                A maximal matching cannot add more edges and still be a matching.
219: (4)                The cardinality of a matching is the number of matched edges.
220: (4)                This method replaces the edge weights with 1 plus the maximum edge weight
221: (4)                minus the original edge weight.
222: (4)                new_weight = (max_weight + 1) - edge_weight
223: (4)                then runs :func:`max_weight_matching` with the new weights.
224: (4)                The max weight matching with these new weights corresponds
225: (4)                to the min weight matching using the original weights.
226: (4)                Adding 1 to the max edge weight keeps all edge weights positive
227: (4)                and as integers if they started as integers.
228: (4)                You might worry that adding 1 to each weight would make the algorithm
229: (4)                favor matchings with more edges. But we use the parameter
230: (4)                `maxcardinality=True` in `max_weight_matching` to ensure that the
231: (4)                number of edges in the competing matchings are the same and thus
232: (4)                the optimum does not change due to changes in the number of edges.
233: (4)                Read the documentation of `max_weight_matching` for more information.
234: (4)                Parameters
235: (4)                ----------
236: (4)                G : NetworkX graph
237: (6)                  Undirected graph
238: (4)                weight: string, optional (default='weight')
239: (7)                   Edge data key corresponding to the edge weight.
240: (7)                   If key not found, uses 1 as weight.
241: (4)                Returns
242: (4)                -------
243: (4)                matching : set
244: (8)                    A minimal weight matching of the graph.

(8)                    A maximal matching of the graph.
(5)                 Examples
(4)                --------
(4)                >>> G = nx.Graph()
(4)                >>> edges = [(1, 2, 6), (1, 3, 2), (2, 3, 1), (2, 4, 7), (3, 5, 9), (4, 5,
3)]
(4)                >>> G.add_weighted_edges_from(edges)
(4)                >>> sorted(nx.max_weight_matching(G))
(4)                [(2, 4), (5, 3)]
(4)                Notes
(4)                -----
(4)                If G has edges with weight attributes the edge data are used as
(4)                weight values else the weights are assumed to be 1.
(4)                This function takes time O(number_of_nodes ** 3).
(4)                If all edge weights are integers, the algorithm uses only integer
(4)                computations.  If floating point weights are used, the algorithm
(4)                could return a slightly suboptimal matching due to numeric
(4)                precision errors.
(4)                This method is based on the "blossom" method for finding augmenting
(4)                paths and the "primal-dual" method for finding a matching of maximum
(4)                weight, both methods invented by Jack Edmonds [1]_.
(4)                Bipartite graphs can also be matched using the functions present in
(4)                :mod:`networkx.algorithms.bipartite.matching`.

97: (4)                 The canonical ordering of nodes (v1, ..., vn) must fulfill the following
98: (4)                 conditions:
99: (4)                 (See Lemma 1 in [2]_)
100: (4)                - For the subgraph G_k of the input graph induced by v1, ..., vk it holds:
101: (8)                    - 2-connected
102: (8)                    - internally triangulated
103: (8)                    - the edge (v1, v2) is part of the outer face
104: (4)                - For a node v(k+1) the following holds:
105: (8)                    - The node v(k+1) is part of the outer face of G_k
106: (8)                    - It has at least two neighbors in G_k
107: (8)                    - All neighbors of v(k+1) in G_k lie consecutively on the outer face
of
108: (10)                     G_k (excluding the edge (v1, v2)).
109: (4)                The algorithm used here starts with G_n (containing all nodes). It first
110: (4)                selects the nodes v1 and v2. And then tries to find the order of the other
111: (4)                nodes by checking which node can be removed in order to fulfill the
112: (4)                conditions mentioned above. This is done by calculating the number of
113: (4)                chords of nodes on the outer face. For more information see [1]_.
114: (4)                Parameters
115: (4)                ----------
116: (4)                embedding : nx.PlanarEmbedding
117: (8)                    The embedding must be triangulated

51: (4)                 True
52: (4)                 When `G` is planar, a `PlanarEmbedding` instance is returned:
53: (4)                 >>> P.get_data()
54: (4)                 {0: [1, 2], 1: [0], 2: [0]}
55: (4)                 Notes
56: (4)                 -----
57: (4)                 A (combinatorial) embedding consists of cyclic orderings of the incident
58: (4)                 edges at each vertex. Given such an embedding there are multiple
approaches
59: (4)                 discussed in literature to drawing the graph (subject to various
60: (4)                 constraints, e.g. integer coordinates), see e.g. [2].
61: (4)                 The planarity check algorithm and extraction of the combinatorial
embedding
62: (4)                 is based on the Left-Right Planarity Test [1].
63: (4)                 A counterexample is only generated if the corresponding parameter is set,
64: (4)                 because the complexity of the counterexample generation is higher.
65: (4)                 See also
66: (4)                 --------
67: (4)                 is_planar :
68: (8)                     Check for planarity without creating a `PlanarEmbedding` or
counterexample.

563: (0)            class PlanarEmbedding(nx.DiGraph):
564: (4)                """Represents a planar graph with its planar embedding.
565: (4)                The planar embedding is given by a `combinatorial embedding
566: (4)                <https://en.wikipedia.org/wiki/Graph_embedding#Combinatorial_embedding>`_.
567: (4)                .. note:: `check_planarity` is the preferred way to check if a graph is
planar.
568: (4)                **Neighbor ordering:**
569: (4)                In comparison to a usual graph structure, the embedding also stores the
570: (4)                order of all neighbors for every vertex.
571: (4)                The order of the neighbors can be given in clockwise (cw) direction or
572: (4)                counterclockwise (ccw) direction. This order is stored as edge attributes
573: (4)                in the underlying directed graph. For the edge (u, v) the edge attribute
574: (4)                'cw' is set to the neighbor of u that follows immediately after v in
575: (4)                clockwise direction.
576: (4)                In order for a PlanarEmbedding to be valid it must fulfill multiple
577: (4)                conditions. It is possible to check if these conditions are fulfilled with
578: (4)                the method :meth:`check_structure`.
579: (4)                The conditions are:
580: (4)                * Edges must go in both directions (because the edge attributes differ)
581: (4)                * Every edge must have a 'cw' and 'ccw' attribute which corresponds to a
582: (6)                  correct planar embedding.
583: (4)                As long as a PlanarEmbedding is invalid only the following methods should
584: (4)                be called:
585: (4)                * :meth:`add_half_edge`
586: (4)                * :meth:`connect_components`
587: (4)                Even though the graph is a subclass of nx.DiGraph, it can still be used
588: (4)                for algorithms that require undirected graphs, because the method
589: (4)                :meth:`is_directed` is overridden. This is possible, because a valid
590: (4)                PlanarGraph must have edges in both directions.
591: (4)                **Half edges:**
592: (4)                In methods like `add_half_edge` the term "half-edge" is used, which is
593: (4)                a term that is used in `doubly connected edge lists
594: (4)                <https://en.wikipedia.org/wiki/Doubly_connected_edge_list>`_. It is used
595: (4)                to emphasize that the edge is only in one direction and there exists
596: (4)                another half-edge in the opposite direction.
597: (4)                While conventional edges always have two faces (including outer face) next
598: (4)                to them, it is possible to assign each half-edge *exactly one* face.
599: (4)                For a half-edge (u, v) that is oriented such that u is below v then the
600: (4)                face that belongs to (u, v) is to the right of this half-edge.
601: (4)                See Also
602: (4)                --------
603: (4)                is_planar :
604: (8)                    Preferred way to check if an existing graph is planar.
605: (4)                check_planarity :
606: (8)                    A convenient way to create a `PlanarEmbedding`. If not planar,
607: (8)                    it returns a subgraph that shows this.
608: (4)                Examples
609: (4)                --------
610: (4)                Create an embedding of a star graph (compare `nx.star_graph(3)`):
611: (4)                >>> G = nx.PlanarEmbedding()
612: (4)                >>> G.add_half_edge(0, 1)
613: (4)                >>> G.add_half_edge(0, 2, ccw=1)
614: (4)                >>> G.add_half_edge(0, 3, ccw=2)
```

```
(4)                 >>> G.add_half_edge(1, 0)
(4)                 >>> G.add_half_edge(2, 0)
(4)                 >>> G.add_half_edge(3, 0)
(4)                 Alternatively the same embedding can also be defined in counterclockwise
(4)                 orientation. The following results in exactly the same PlanarEmbedding:
(4)                 >>> G = nx.PlanarEmbedding()
(4)                 >>> G.add_half_edge(0, 1)
(4)                 >>> G.add_half_edge(0, 3, cw=1)
(4)                 >>> G.add_half_edge(0, 2, cw=3)
(4)                 >>> G.add_half_edge(1, 0)
(4)                 >>> G.add_half_edge(2, 0)
(4)                 >>> G.add_half_edge(3, 0)
(4)                 After creating a graph, it is possible to validate that the
PlanarEmbedding
(4)                 object is correct:
(4)                 >>> G.check_structure()
(4)                 """

def tutte_polynomial(G):
    r"""Returns the Tutte polynomial of `G`
    This function computes the Tutte polynomial via an iterative version of
    the deletion-contraction algorithm.
    The Tutte polynomial `T_G(x, y)` is a fundamental graph polynomial invariant in
    two variables. It encodes a wide array of information related to the
    edge-connectivity of a graph; "Many problems about graphs can be reduced to
    problems of finding and evaluating the Tutte polynomial at certain values" [1]_.
    In fact, every deletion-contraction-expressible feature of a graph is a
    specialization of the Tutte polynomial [2]_ (see Notes for examples).
    There are several equivalent definitions; here are three:
    Def 1 (rank-nullity expansion): For `G` an undirected graph, `n(G)` the
    number of vertices of `G`, `E` the edge set of `G`, `V` the vertex set of
    `G`, and `c(A)` the number of connected components of the graph with vertex
    set `V` and edge set `A` [3]_:
    .. math::
        T_G(x, y) = \sum_{A \in E} (x-1)^{c(A) - c(E)} (y-1)^{c(A) + |A| - n(G)}
    Def 2 (spanning tree expansion): Let `G` be an undirected graph, `T` a spanning
    tree of `G`, and `E` the edge set of `G`. Let `E` have an arbitrary strict
    linear order `L`. Let `B_e` be the unique minimal nonempty edge cut of
    $E \setminus T \cup {e}$. An edge `e` is internally active with respect to
    `T` and `L` if `e` is the least edge in `B_e` according to the linear order
    `L`. The internal activity of `T` (denoted `i(T)`) is the number of edges
    in $E \setminus T$ that are internally active with respect to `T` and `L`.
    Let `P_e` be the unique path in $T \cup {e}$ whose source and target vertex
    are the same. An edge `e` is externally active with respect to `T` and `L`
    if `e` is the least edge in `P_e` according to the linear order `L`. The
    external activity of `T` (denoted `e(T)`) is the number of edges in
    $E \setminus T$ that are externally active with respect to `T` and `L`.
    Then [4]_ [5]_:
    .. math::
        T_G(x, y) = \sum_{T \text{ a spanning tree of } G} x^{i(T)} y^{e(T)}
    Def 3 (deletion-contraction recurrence): For `G` an undirected graph, `G-e`
    the graph obtained from `G` by deleting edge `e`, `G/e` the graph obtained
    from `G` by contracting edge `e`, `k(G)` the number of cut-edges of `G`,
    and `l(G)` the number of self-loops of `G`:
    .. math::
        T_G(x, y) = \begin{cases}
           x^{k(G)} y^{l(G)}, & \text{if all edges are cut-edges or self-loops} \\
           T_{G-e}(x, y) + T_{G/e}(x, y), & \text{otherwise, for an arbitrary edge $e$ not a cut-edge or loop}
        \end{cases}
```

```
66: (4)                 Parameters
67: (4)                 ----------
68: (4)                 G : NetworkX graph

(4)                 For `G` an undirected graph, `n(G)` the number of vertices of `G`, `k_0 =
0`,
(4)                 and `k_i` the number of distinct ways to color the vertices of `G` with
`i`
(4)                 unique colors (for `i` a natural number at most `n(G)`), `X_G(x)` is the
(4)                 unique Lagrange interpolating polynomial of degree `n(G)` through the
points
(4)                 `(0, k_0), (1, k_1), \dots, (n(G), k_{n(G)})` [2]_.
(4)                 Def 3 (chromatic recurrence):
(4)                 For `G` an undirected graph, `G-e` the graph obtained from `G` by deleting
(4)                 edge `e`, `G/e` the graph obtained from `G` by contracting edge `e`,
`n(G)`
(4)                 the number of vertices of `G`, and `e(G)` the number of edges of `G` [3]_:
(4)                 .. math::
(8)                     X_G(x) = \begin{cases}
(11)                       x^{n(G)}, & \text{if $e(G)=0$} \\
(11)                       X_{G-e}(x) - X_{G/e}(x), & \text{otherwise, for an arbitrary edge
$e$}
(8)                     \end{cases}
(4)                 This formulation is also known as the Fundamental Reduction Theorem [4]_.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX graph
(4)                 Returns
(4)                 -------
(4)                 instance of `sympy.core.add.Add`
(8)                     A Sympy expression representing the chromatic polynomial for `G`.
(4)                 Examples
(4)                 --------
(4)                 >>> C = nx.cycle_graph(5)
(4)                 >>> nx.chromatic_polynomial(C)
(4)                 x**5 - 5*x**4 + 10*x**3 - 10*x**2 + 4*x
(4)                 >>> G = nx.complete_graph(4)
(4)                 >>> nx.chromatic_polynomial(G)
(4)                 x**4 - 6*x**3 + 11*x**2 - 6*x
(4)                 Notes

27: (8)                     null-model for normalization.
28: (4)                 seed : integer, random_state, or None (default)
29: (8)                     Indicator of random number generation state.
30: (8)                     See :ref:`Randomness<randomness>`.
31: (4)                 Returns
32: (4)                 -------
```

```
    rc : dictionary
       A dictionary, keyed by degree, with rich-club coefficient values.
    Raises
    ------
    NetworkXError
        If `G` has fewer than four nodes and ``normalized=True``.
        A randomly sampled graph for normalization cannot be generated in this case.
    Examples
    --------
    >>> G = nx.Graph([(0, 1), (0, 2), (1, 2), (1, 3), (1, 4), (4, 5)])
    >>> rc = nx.rich_club_coefficient(G, normalized=False, seed=42)
    >>> rc[0]
    0.4
    Notes
    -----
    The rich club definition and algorithm are found in [1]_.  This
    algorithm ignores any edge weights and is not defined for directed
    graphs or graphs with parallel edges or self loops.
    Normalization is done by computing the rich club coefficient for a randomly
    sampled graph with the same degree distribution as `G` by
    repeatedly swapping the endpoints of existing edges. For graphs with fewer than 4
    nodes, it is not possible to generate a random graph with a prescribed
    degree distribution, as the degree distribution fully determines the graph
    (hence making the coefficients trivially normalized to 1).
    This function raises an exception in this case.
    Estimates for appropriate values of `Q` are found in [2]_.

53: (4)                 Parameters
```

```
    ----------
    G1, G2: graphs
        The two graphs G1 and G2 must be of the same type.
    node_match : callable
        A function that returns True if node n1 in G1 and n2 in G2
        should be considered equal during matching.
        The function will be called like
           node_match(G1.nodes[n1], G2.nodes[n2]).
        That is, the function will receive the node attribute
        dictionaries for n1 and n2 as inputs.
        Ignored if node_subst_cost is specified.  If neither
        node_match nor node_subst_cost are specified then node
        attributes are not considered.
    edge_match : callable
        A function that returns True if the edge attribute dictionaries
        for the pair of nodes (u1, v1) in G1 and (u2, v2) in G2 should
        be considered equal during matching.
        The function will be called like
           edge_match(G1[u1][v1], G2[u2][v2]).
        That is, the function will receive the edge attribute
        dictionaries of the edges under consideration.
        Ignored if edge_subst_cost is specified.  If neither
        edge_match nor edge_subst_cost are specified then edge
        attributes are not considered.
    node_subst_cost, node_del_cost, node_ins_cost : callable
        Functions that return the costs of node substitution, node
        deletion, and node insertion, respectively.
        The functions will be called like
           node_subst_cost(G1.nodes[n1], G2.nodes[n2]),
           node_del_cost(G1.nodes[n1]),
           node_ins_cost(G2.nodes[n2]).
        That is, the functions will receive the node attribute
        dictionaries as inputs.  The functions are expected to return
        positive numeric values.
        Function node_subst_cost overrides node_match if specified.
        If neither node_match nor node_subst_cost are specified then
        default node substitution cost of 0 is used (node attributes
        are not considered during matching).
        If node_del_cost is not specified then default node deletion
        cost of 1 is used.  If node_ins_cost is not specified then
        default node insertion cost of 1 is used.
    edge_subst_cost, edge_del_cost, edge_ins_cost : callable
        Functions that return the costs of edge substitution, edge
        deletion, and edge insertion, respectively.
        The functions will be called like
           edge_subst_cost(G1[u1][v1], G2[u2][v2]),
           edge_del_cost(G1[u1][v1]),
           edge_ins_cost(G2[u2][v2]).
        That is, the functions will receive the edge attribute
        dictionaries as inputs.  The functions are expected to return
        positive numeric values.
        Function edge_subst_cost overrides edge_match if specified.
        If neither edge_match nor edge_subst_cost are specified then
        default edge substitution cost of 0 is used (edge attributes
        are not considered during matching).
        If edge_del_cost is not specified then default edge deletion
        cost of 1 is used.  If edge_ins_cost is not specified then
        default edge insertion cost of 1 is used.
    roots : 2-tuple
        Tuple where first element is a node in G1 and the second
        is a node in G2.
        These nodes are forced to be matched in the comparison to
        allow comparison between rooted graphs.
    upper_bound : numeric
        Maximum edit distance to consider.  Return None if no edit
        distance under or equal to upper_bound exists.
    timeout : numeric
        Maximum number of seconds to execute.
        After timeout is met, the current best GED is returned.
```

```

```

```
(8)                 should be considered equal during matching.
(8)                 The function will be called like
(11)                   node_match(G1.nodes[n1], G2.nodes[n2]).
(8)                 That is, the function will receive the node attribute
(8)                 dictionaries for n1 and n2 as inputs.
(8)                 Ignored if node_subst_cost is specified.  If neither
(8)                 node_match nor node_subst_cost are specified then node
(8)                 attributes are not considered.
(4)             edge_match : callable
(8)                 A function that returns True if the edge attribute dictionaries
(8)                 for the pair of nodes (u1, v1) in G1 and (u2, v2) in G2 should
(8)                 be considered equal during matching.
(8)                 The function will be called like
(11)                   edge_match(G1[u1][v1], G2[u2][v2]).
(8)                 That is, the function will receive the edge attribute
(8)                 dictionaries of the edges under consideration.
(8)                 Ignored if edge_subst_cost is specified.  If neither
(8)                 edge_match nor edge_subst_cost are specified then edge
(8)                 attributes are not considered.
(4)             node_subst_cost, node_del_cost, node_ins_cost : callable
(8)                 Functions that return the costs of node substitution, node
(8)                 deletion, and node insertion, respectively.
(8)                 The functions will be called like
(11)                   node_subst_cost(G1.nodes[n1], G2.nodes[n2]),
(11)                   node_del_cost(G1.nodes[n1]),
(11)                   node_ins_cost(G2.nodes[n2]).
(8)                 That is, the functions will receive the node attribute
(8)                 dictionaries as inputs.  The functions are expected to return
(8)                 positive numeric values.
(8)                 Function node_subst_cost overrides node_match if specified.
(8)                 If neither node_match nor node_subst_cost are specified then
(8)                 default node substitution cost of 0 is used (node attributes
(8)                 are not considered during matching).
(8)                 If node_del_cost is not specified then default node deletion
(8)                 cost of 1 is used.  If node_ins_cost is not specified then
(8)                 default node insertion cost of 1 is used.
(4)             edge_subst_cost, edge_del_cost, edge_ins_cost : callable
(8)                 Functions that return the costs of edge substitution, edge
(8)                 deletion, and edge insertion, respectively.
(8)                 The functions will be called like
(11)                   edge_subst_cost(G1[u1][v1], G2[u2][v2]),
(11)                   edge_del_cost(G1[u1][v1]),
(11)                   edge_ins_cost(G2[u2][v2]).
(8)                 That is, the functions will receive the edge attribute
(8)                 dictionaries as inputs.  The functions are expected to return
(8)                 positive numeric values.
(8)                 Function edge_subst_cost overrides edge_match if specified.
(8)                 If neither edge_match nor edge_subst_cost are specified then
(8)                 default edge substitution cost of 0 is used (edge attributes
(8)                 are not considered during matching).
(8)                 If edge_del_cost is not specified then default edge deletion
(8)                 cost of 1 is used.  If edge_ins_cost is not specified then
(8)                 default edge insertion cost of 1 is used.
(4)             upper_bound : numeric
(8)                 Maximum edit distance to consider.
(4)             Returns
(4)             -------
(4)             edit_paths : list of tuples (node_edit_path, edge_edit_path)
(8)                 node_edit_path : list of tuples (u, v)
(8)                 edge_edit_path : list of tuples ((u1, v1), (u2, v2))
(4)             cost : numeric
(8)                 Optimal edit path cost (graph edit distance). When the cost
(8)                 is zero, it indicates that `G1` and `G2` are isomorphic.
(4)             Examples
(4)             --------
(4)             >>> G1 = nx.cycle_graph(4)
(4)             >>> G2 = nx.wheel_graph(5)
(4)             >>> paths, cost = nx.optimal_edit_paths(G1, G2)
(4)             >>> len(paths)
```

```
(4)                 40
(4)                 >>> cost
(4)                 5.0
(4)                 Notes
(4)                 -----
(4)                 To transform `G1` into a graph isomorphic to `G2`, apply the node
(4)                 and edge edits in the returned ``edit_paths``.
(4)                 In the case of isomorphic graphs, the cost is zero, and the paths
(4)                 represent different isomorphic mappings (isomorphisms). That is, the
(4)                 edits involve renaming nodes and edges to match the structure of `G2`.

996: (4)                max_iterations : integer
997: (8)                    Maximum number of iterations.
998: (4)                tolerance : float
999: (8)                    Error tolerance used to check convergence. When an iteration of
1000: (8)                   the algorithm finds that no similarity value changes more than
1001: (8)                   this amount, the algorithm halts.
1002: (4)               Returns
1003: (4)               -------
1004: (4)               similarity : dictionary or float
1005: (8)                   If ``source`` and ``target`` are both ``None``, this returns a
1006: (8)                   dictionary of dictionaries, where keys are node pairs and value
1007: (8)                   are similarity of the pair of nodes.
1008: (8)                   If ``source`` is not ``None`` but ``target`` is, this returns a
1009: (8)                   dictionary mapping node to the similarity of ``source`` and that
1010: (8)                   node.
```

```
(8)                 If neither ``source`` nor ``target`` is ``None``, this returns
(8)                 the similarity value for the given pair of nodes.
(4)             Raises
(4)             ------
(4)             ExceededMaxIterations
(8)                 If the algorithm does not converge within ``max_iterations``.
(4)             NodeNotFound
(8)                 If either ``source`` or ``target`` is not in `G`.
(4)             Examples
(4)             --------
(4)             >>> G = nx.cycle_graph(2)
(4)             >>> nx.simrank_similarity(G)
(4)             {0: {0: 1.0, 1: 0.0}, 1: {0: 0.0, 1: 1.0}}
(4)             >>> nx.simrank_similarity(G, source=0)
(4)             {0: 1.0, 1: 0.0}
(4)             >>> nx.simrank_similarity(G, source=0, target=0)
(4)             1.0
(4)             The result of this function can be converted to a numpy array
(4)             representing the SimRank matrix by using the node order of the
(4)             graph to determine which row and column represent each node.
(4)             Other ordering of nodes is also possible.
(4)             >>> import numpy as np
(4)             >>> sim = nx.simrank_similarity(G)
(4)             >>> np.array([[sim[u][v] for v in G] for u in G])
(4)             array([[1., 0.],
(11)                   [0., 1.]])
(4)             >>> sim_1d = nx.simrank_similarity(G, source=0)
(4)             >>> np.array([sim[0][v] for v in G])
(4)             array([1., 0.])

(4)             The SimRank algorithm for determining node similarity is defined in
(4)             [1]_.
(4)             Parameters
(4)             ----------
(4)             G : NetworkX graph
(8)                 A NetworkX graph
(4)             source : node
(8)                 If this is specified, the returned dictionary maps each node
(8)                 ``v`` in the graph to the similarity between ``source`` and
(8)                 ``v``.
(4)             target : node
(8)                 If both ``source`` and ``target`` are specified, the similarity
(8)                 value between ``source`` and ``target`` is returned. If
(8)                 ``target`` is specified but ``source`` is not, this argument is
(8)                 ignored.
(4)             importance_factor : float
(8)                 The relative importance of indirect neighbors with respect to
(8)                 direct neighbors.
(4)             max_iterations : integer
(8)                 Maximum number of iterations.
```

```
    tolerance : float
        Error tolerance used to check convergence. When an iteration of
        the algorithm finds that no similarity value changes more than
        this amount, the algorithm halts.
    Returns
    -------
    similarity : numpy array or float
        If ``source`` and ``target`` are both ``None``, this returns a
        2D array containing SimRank scores of the nodes.
        If ``source`` is not ``None`` but ``target`` is, this returns an
        1D array containing SimRank scores of ``source`` and that
        node.
        If neither ``source`` nor ``target`` is ``None``, this returns
        the similarity value for the given pair of nodes.
    Examples
    --------
    >>> G = nx.cycle_graph(2)
    >>> nx.similarity._simrank_similarity_numpy(G)
    array([[1., 0.],
           [0., 1.]])
    >>> nx.similarity._simrank_similarity_numpy(G, source=0)
    array([1., 0.])
    >>> nx.similarity._simrank_similarity_numpy(G, source=0, target=0)
    1.0

def panther_similarity(
    G, source, k=5, path_length=5, c=0.5, delta=0.1, eps=None, weight="weight"
):
    r"""Returns the Panther similarity of nodes in the graph `G` to node ``v``.
    Panther is a similarity metric that says "two objects are considered
    to be similar if they frequently appear on the same paths." [1]_.
    Parameters
    ----------
    G : NetworkX graph
        A NetworkX graph
    source : node
        Source node for which to find the top `k` similar other nodes
    k : int (default = 5)
```

```
        The number of most similar nodes to return.
    path_length : int (default = 5)
        How long the randomly generated paths should be (``T`` in [1]_)
    c : float (default = 0.5)
        A universal positive constant used to scale the number
        of sample random paths to generate.
    delta : float (default = 0.1)
        The probability that the similarity $S$ is not an epsilon-approximation to (R, phi),
        where $R$ is the number of random paths and $\phi$ is the probability
        that an element sampled from a set $A \subseteq D$, where $D$ is the domain.
    eps : float or None (default = None)
        The error bound. Per [1]_, a good value is ``sqrt(1/|E|)``. Therefore,
        if no value is provided, the recommended computed value will be used.
    weight : string or None, optional (default="weight")
        The name of an edge attribute that holds the numerical value
        used as a weight. If None then each edge has weight 1.
    Returns
    -------
    similarity : dictionary
        Dictionary of nodes to similarity scores (as floats). Note:
        the self-similarity (i.e., ``v``) will not be included in
        the returned dictionary. So, for ``k = 5``, a dictionary of
        top 4 nodes and their similarity scores will be returned.
    Raises
    ------
    NetworkXUnfeasible
        If `source` is an isolated node.
    NodeNotFound
        If `source` is not in `G`.
    Notes
    -----
        The isolated nodes in `G` are ignored.
    Examples
    --------
    >>> G = nx.star_graph(10)
    >>> sim = nx.panther_similarity(G, 0)

(8)                 used as a weight. If None then each edge has weight 1.
(4)             seed : integer, random_state, or None (default)
(8)                 Indicator of random number generation state.
(8)                 See :ref:`Randomness<randomness>`.
(4)             Returns
(4)             -------
(4)             paths : generator of lists
(8)                 Generator of `sample_size` paths each with length `path_length`.
(4)             Examples
(4)             --------
(4)             Note that the return value is the list of paths:
(4)             >>> G = nx.star_graph(3)
(4)             >>> random_path = nx.generate_random_paths(G, 2)
(4)             By passing a dictionary into `index_map`, it will build an
(4)             inverted index mapping of nodes to the paths in which that node is present:
(4)             >>> G = nx.star_graph(3)
(4)             >>> index_map = {}
(4)             >>> random_path = nx.generate_random_paths(G, 3, index_map=index_map)
(4)             >>> paths_containing_node_0 = [
(4)             ...     random_path[path_idx] for path_idx in index_map.get(0, [])
(4)             ... ]
(4)             References

15: (4)                 A *simple path* in a graph is a nonempty sequence of nodes in which
16: (4)                 no node appears more than once in the sequence, and each adjacent
17: (4)                 pair of nodes in the sequence is adjacent in the graph.
18: (4)                 Parameters
19: (4)                 ----------
20: (4)                 G : graph
21: (8)                     A NetworkX graph.
22: (4)                 nodes : list
23: (8)                     A list of one or more nodes in the graph `G`.
```

```
(4)                 Returns
(4)                 -------
(4)                 bool
(8)                     Whether the given list of nodes represents a simple path in `G`.
(4)                 Notes
(4)                 -----
(4)                 An empty list of nodes is not a path but a list of one node is a
(4)                 path. Here's an explanation why.
(4)                 This function operates on *node paths*. One could also consider
(4)                 *edge paths*. There is a bijection between node paths and edge
(4)                 paths.
(4)                 The *length of a path* is the number of edges in the path, so a list
(4)                 of nodes of length *n* corresponds to a path of length *n* - 1.
(4)                 Thus the smallest edge path would be a list of zero edges, the empty
(4)                 path. This corresponds to a list of one node.
(4)                 To convert between a node path and an edge path, you can use code
(4)                 like the following::
(8)                     >>> from networkx.utils import pairwise
(8)                     >>> nodes = [0, 1, 2, 3]
(8)                     >>> edges = list(pairwise(nodes))
(8)                     >>> edges
(8)                     [(0, 1), (1, 2), (2, 3)]
(8)                     >>> nodes = [edges[0][0]] + [v for u, v in edges]
(8)                     >>> nodes
(8)                     [0, 1, 2, 3]
(4)                 Examples
(4)                 --------
(4)                 >>> G = nx.cycle_graph(4)
(4)                 >>> nx.is_simple_path(G, [2, 3, 0])
(4)                 True
(4)                 >>> nx.is_simple_path(G, [0, 2])
(4)                 False
(4)                 """
(4)                 if len(nodes) == 0:
(8)                     return False
(4)                 if len(nodes) == 1:
(8)                     return nodes[0] in G
(4)                 if not all(n in G for n in nodes):
(8)                     return False
(4)                 if len(set(nodes)) != len(nodes):
(8)                     return False
(4)                 return all(v in G[u] for u, v in pairwise(nodes))
(0)             @nx._dispatchable
(0)             def all_simple_paths(G, source, target, cutoff=None):
(4)                 """Generate all simple paths in the graph G from source to target.
(4)                 A simple path is a path with no repeated nodes.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX graph
(4)                 source : node
(7)                    Starting node for path
(4)                 target : nodes
(7)                    Single node or iterable of nodes at which to end path
(4)                 cutoff : integer, optional
(8)                     Depth to stop the search. Only paths of length <= cutoff are returned.
(4)                 Returns
(4)                 -------
(4)                 path_generator: generator
(7)                    A generator that produces lists of simple paths.  If there are no paths
(7)                    between the source and target within the given cutoff the generator
(7)                    produces no output. If it is possible to traverse the same sequence of
(7)                    nodes in multiple ways, namely through parallel edges, then it will be
(7)                    returned multiple times (once for each viable edge combination).
(4)                 Examples
(4)                 --------
(4)                 This iterator generates lists of nodes::
(8)                     >>> G = nx.complete_graph(4)
(8)                     >>> for path in nx.all_simple_paths(G, source=0, target=3):
(8)                     ...     print(path)
```

```
93: (8)                     ...
94: (8)                     [0, 1, 2, 3]
95: (8)                     [0, 1, 3]
96: (8)                     [0, 2, 1, 3]
97: (8)                     [0, 2, 3]
98: (8)                     [0, 3]
99: (4)                 You can generate only those paths that are shorter than a certain
100: (4)                length by using the `cutoff` keyword argument::
101: (8)                    >>> paths = nx.all_simple_paths(G, source=0, target=3, cutoff=2)
102: (8)                    >>> print(list(paths))
103: (8)                    [[0, 1, 3], [0, 2, 3], [0, 3]]
104: (4)                To get each path as the corresponding list of edges, you can use the
105: (4)                :func:`networkx.utils.pairwise` helper function::
106: (8)                    >>> paths = nx.all_simple_paths(G, source=0, target=3)
107: (8)                    >>> for path in map(nx.utils.pairwise, paths):
108: (8)                    ...     print(list(path))
109: (8)                    [(0, 1), (1, 2), (2, 3)]
110: (8)                    [(0, 1), (1, 3)]
111: (8)                    [(0, 2), (2, 1), (1, 3)]
112: (8)                    [(0, 2), (2, 3)]
113: (8)                    [(0, 3)]
114: (4)                Pass an iterable of nodes as target to generate all paths ending in any of
several nodes::
115: (8)                    >>> G = nx.complete_graph(4)
116: (8)                    >>> for path in nx.all_simple_paths(G, source=0, target=[3, 2]):
117: (8)                    ...     print(path)
118: (8)                    ...
119: (8)                    [0, 1, 2]
120: (8)                    [0, 1, 2, 3]
121: (8)                    [0, 1, 3]
122: (8)                    [0, 1, 3, 2]
123: (8)                    [0, 2]

(8)                 [[0, 1, 2], [0, 3, 2]]
(4)             Iterate over each path from the root nodes to the leaf nodes in a
(4)             directed acyclic graph passing all leaves together to avoid unnecessary
(4)             compute::
(8)                 >>> G = nx.DiGraph([(0, 1), (2, 1), (1, 3), (1, 4)])
(8)                 >>> roots = (v for v, d in G.in_degree() if d == 0)
(8)                 >>> leaves = [v for v, d in G.out_degree() if d == 0]
(8)                 >>> all_paths = []
(8)                 >>> for root in roots:
(8)                 ...     paths = nx.all_simple_paths(G, root, leaves)
(8)                 ...     all_paths.extend(paths)
(8)                 >>> all_paths
(8)                 [[0, 1, 3], [0, 1, 4], [2, 1, 3], [2, 1, 4]]
(4)             If parallel edges offer multiple ways to traverse a given sequence of
(4)             nodes, this sequence of nodes will be returned multiple times:
(8)                 >>> G = nx.MultiDiGraph([(0, 1), (0, 1), (1, 2)])
(8)                 >>> list(nx.all_simple_paths(G, 0, 2))
(8)                 [[0, 1, 2], [0, 1, 2]]
(4)             Notes
(4)             -----
(4)             This algorithm uses a modified depth-first search to generate the
(4)             paths [1]_.  A single path can be found in $O(V+E)$ time but the
(4)             number of simple paths in a graph can be very large, e.g. $O(n!)$ in
(4)             the complete graph of order $n$.
(4)             This function does not check that a path exists between `source` and
(4)             `target`. For large graphs, this may result in very long runtimes.
(4)             Consider using `has_path` to check that a path exists between `source` and
(4)             `target` before calling this function on large graphs.

(0)         def all_simple_edge_paths(G, source, target, cutoff=None):
(4)             """Generate lists of edges for all simple paths in G from source to
target.
(4)             A simple path is a path with no repeated nodes.
(4)             Parameters
(4)             ----------
(4)             G : NetworkX graph
(4)             source : node
(7)                Starting node for path
(4)             target : nodes
(7)                Single node or iterable of nodes at which to end path
(4)             cutoff : integer, optional
(8)                 Depth to stop the search. Only paths of length <= cutoff are returned.
(4)             Returns
(4)             -------
(4)             path_generator: generator
(7)                A generator that produces lists of simple paths.  If there are no paths
(7)                between the source and target within the given cutoff the generator
(7)                produces no output.
(7)                For multigraphs, the list of edges have elements of the form `(u,v,k)`.
(7)                Where `k` corresponds to the edge key.
(4)             Examples
(4)             --------
(4)             Print the simple path edges of a Graph::
(8)                 >>> g = nx.Graph([(1, 2), (2, 4), (1, 3), (3, 4)])
(8)                 >>> for path in sorted(nx.all_simple_edge_paths(g, 1, 4)):
(8)                 ...     print(path)
(8)                 [(1, 2), (2, 4)]
```

```
(8)                 [(1, 3), (3, 4)]
(4)             Print the simple path edges of a MultiGraph. Returned edges come with
(4)             their associated keys::
(8)                 >>> mg = nx.MultiGraph()
(8)                 >>> mg.add_edge(1, 2, key="k0")
(8)                 'k0'
(8)                 >>> mg.add_edge(1, 2, key="k1")
(8)                 'k1'
(8)                 >>> mg.add_edge(2, 3, key="k0")
(8)                 'k0'
(8)                 >>> for path in sorted(nx.all_simple_edge_paths(mg, 1, 3)):
(8)                 ...     print(path)
(8)                 [(1, 2, 'k0'), (2, 3, 'k0')]
(8)                 [(1, 2, 'k1'), (2, 3, 'k0')]
(4)             When ``source`` is one of the targets, the empty path starting and ending at
(4)             ``source`` without traversing any edge is considered a valid simple edge path
(4)             and is included in the results:
(8)                 >>> G = nx.Graph()
(8)                 >>> G.add_node(0)
(8)                 >>> paths = list(nx.all_simple_edge_paths(G, 0, 0))
(8)                 >>> for path in paths:
(8)                 ...     print(path)
(8)                 []
(8)                 >>> len(paths)
(8)                 1
(4)             Notes

560: (0)            ):
561: (4)                """Dijkstra's algorithm for shortest paths using bidirectional search.
```

```
(4)    This function returns the shortest path between source and target
(4)    ignoring nodes and edges in the containers ignore_nodes and
(4)    ignore_edges.
(4)    This is a custom modification of the standard Dijkstra bidirectional
(4)    shortest path implementation at networkx.algorithms.weighted
(4)    Parameters
(4)    ----------
(4)    G : NetworkX graph
(4)    source : node
(7)       Starting node.
(4)    target : node
(7)       Ending node.
(4)    weight: string, function, optional (default='weight')
(7)       Edge data key or weight function corresponding to the edge weight
(4)    ignore_nodes : container of nodes
(7)       nodes to ignore, optional
(4)    ignore_edges : container of edges
(7)       edges to ignore, optional
(4)    Returns
(4)    -------
(4)    length : number
(8)        Shortest path length.
(4)    Returns a tuple of two dictionaries keyed by node.
(4)    The first dictionary stores distance from the source.
(4)    The second stores the path from the source to that node.
(4)    Raises
(4)    ------
(4)    NetworkXNoPath
(8)        If no path exists between source and target.
(4)    Notes
(4)    -----
(4)    Edge weight attributes must be numerical.
(4)    Distances are calculated as sums of weighted edges traversed.
(4)    In practice  bidirectional Dijkstra is much more than twice as fast as
(4)    ordinary Dijkstra.
(4)    Ordinary Dijkstra expands nodes in a sphere-like manner from the
(4)    source. The radius of this sphere will eventually be the length
(4)    of the shortest path. Bidirectional Dijkstra will expand nodes
(4)    from both the source and the target, making two spheres of half
(4)    this radius. Volume of the first sphere is pi*r*r while the
(4)    others are 2*pi*r/2*r/2, making up half the volume.
(4)    This algorithm is not guaranteed to work if edge weights
(4)    are negative or are floating point numbers
(4)    (overflows and roundoff errors can cause problems).

40: (4)                 r"""Returns the effective size of all nodes in the graph ``G``.
41: (4)                 The *effective size* of a node's ego network is based on the concept
42: (4)                 of redundancy. A person's ego network has redundancy to the extent
43: (4)                 that her contacts are connected to each other as well. The
44: (4)                 nonredundant part of a person's relationships is the effective
```

```
size of her ego network [1]_.  Formally, the effective size of a
node $u$, denoted $e(u)$, is defined by
.. math::
   e(u) = \sum_{v \in N(u) \setminus \{u\}}
   \left(1 - \sum_{w \in N(v)} p_{uw} m_{vw}\right)
where $N(u)$ is the set of neighbors of $u$ and $p_{uw}$ is the
normalized mutual weight of the (directed or undirected) edges
joining $u$ and $v$, for each vertex $u$ and $v$ [1]_. And $m_{vw}$
is the mutual weight of $v$ and $w$ divided by $v$ highest mutual
weight with any of its neighbors. The *mutual weight* of $u$ and $v$
is the sum of the weights of edges joining them (edge weights are
assumed to be one if the graph is unweighted).
For the case of unweighted and undirected graphs, Borgatti proposed
a simplified formula to compute effective size [2]_
.. math::
   e(u) = n - \frac{2t}{n}
where `t` is the number of ties in the ego network (not including
ties to ego) and `n` is the number of nodes (excluding ego).
Parameters
----------
G : NetworkX graph
    The graph containing ``v``. Directed graphs are treated like
    undirected graphs when computing neighbors of ``v``.
nodes : container, optional
    Container of nodes in the graph ``G`` to compute the effective size.
    If None, the effective size of every node is computed.
weight : None or string, optional
  If None, all edge weights are considered equal.
  Otherwise holds the name of the edge attribute used as weight.
Returns
-------
dict
    Dictionary with nodes as keys and the effective size of the node as values.
Notes
-----
Burt also defined the related concept of *efficiency* of a node's ego
network, which is its effective size divided by the degree of that
node [1]_. So you can easily compute efficiency:
>>> G = nx.DiGraph()
>>> G.add_edges_from([(0, 1), (0, 2), (1, 0), (2, 1)])
>>> esize = nx.effective_size(G)
>>> efficiency = {n: v / G.degree(n) for n, v in esize.items()}

File 54 - summarization.py:

```
1: (0)              """
2: (0)              Graph summarization finds smaller representations of graphs resulting in
faster
3: (0)              runtime of algorithms, reduced storage needs, and noise reduction.
4: (0)              Summarization has applications in areas such as visualization, pattern mining,
5: (0)              clustering and community detection, and more.  Core graph summarization
6: (0)              techniques are grouping/aggregation, bit-compression,
7: (0)              simplification/sparsification, and influence based. Graph summarization
8: (0)              algorithms often produce either summary graphs in the form of supergraphs or
9: (0)              sparsified graphs, or a list of independent structures. Supergraphs are the
10: (0)             most common product, which consist of supernodes and original nodes and are
11: (0)             connected by edges and superedges, which represent aggregate edges between
12: (0)             nodes and supernodes.
13: (0)             Grouping/aggregation based techniques compress graphs by representing
14: (0)             close/connected nodes and edges in a graph by a single node/edge in a
15: (0)             supergraph. Nodes can be grouped together into supernodes based on their
16: (0)             structural similarities or proximity within a graph to reduce the total number
17: (0)             of nodes in a graph. Edge-grouping techniques group edges into lossy/lossless
18: (0)             nodes called compressor or virtual nodes to reduce the total number of edges
in
19: (0)             a graph. Edge-grouping techniques can be lossless, meaning that they can be
20: (0)             used to re-create the original graph, or techniques can be lossy, requiring
21: (0)             less space to store the summary graph, but at the expense of lower
```

```
 22: (0)             reconstruction accuracy of the original graph.
 23: (0)             Bit-compression techniques minimize the amount of information needed to
 24: (0)             describe the original graph, while revealing structural patterns in the
 25: (0)             original graph.  The two-part minimum description length (MDL) is often used
to
 26: (0)             represent the model and the original graph in terms of the model.  A key
 27: (0)             difference between graph compression and graph summarization is that graph
 28: (0)             summarization focuses on finding structural patterns within the original
graph,
 29: (0)             whereas graph compression focuses on compressions the original graph to be as
 30: (0)             small as possible.  **NOTE**: Some bit-compression methods exist solely to
 31: (0)             compress a graph without creating a summary graph or finding comprehensible
 32: (0)             structural patterns.
 33: (0)             Simplification/Sparsification techniques attempt to create a sparse
 34: (0)             representation of a graph by removing unimportant nodes and edges from the
 35: (0)             graph.  Sparsified graphs differ from supergraphs created by
 36: (0)             grouping/aggregation by only containing a subset of the original nodes and
 37: (0)             edges of the original graph.
 38: (0)             Influence based techniques aim to find a high-level description of influence
 39: (0)             propagation in a large graph.  These methods are scarce and have been mostly
 40: (0)             applied to social graphs.
 41: (0)             *dedensification* is a grouping/aggregation based technique to compress the
 42: (0)             neighborhoods around high-degree nodes in unweighted graphs by adding
 43: (0)             compressor nodes that summarize multiple edges of the same type to
 44: (0)             high-degree nodes (nodes with a degree greater than a given threshold).
 45: (0)             Dedensification was developed for the purpose of increasing performance of
 46: (0)             query processing around high-degree nodes in graph databases and enables
direct
 47: (0)             operations on the compressed graph.  The structural patterns surrounding
 48: (0)             high-degree nodes in the original is preserved while using fewer edges and
 49: (0)             adding a small number of compressor nodes.  The degree of nodes present in the
 50: (0)             original graph is also preserved. The current implementation of
dedensification
 51: (0)             supports graphs with one edge type.
 52: (0)             For more information on graph summarization, see `Graph Summarization Methods
 53: (0)             and Applications: A Survey <https://dl.acm.org/doi/abs/10.1145/3186727>`_
 54: (0)             """

 81: (4)                 Notes
 82: (4)                 -----
 83: (4)                 According to the algorithm in [1]_, removes edges in a graph by
 84: (4)                 compressing/decompressing the neighborhoods around high degree nodes by
```

```
    adding compressor nodes that summarize multiple edges of the same type
    to high-degree nodes.  Dedensification will only add a compressor node when

    doing so will reduce the total number of edges in the given graph. This
    implementation currently supports graphs with a single edge type.
    Examples
    --------
    Dedensification will only add compressor nodes when doing so would result
    in fewer edges::
        >>> original_graph = nx.DiGraph()
        >>> original_graph.add_nodes_from(
        ...     ["1", "2", "3", "4", "5", "6", "A", "B", "C"]
        ... )
        >>> original_graph.add_edges_from(
        ...     [
        ...         ("1", "C"), ("1", "B"),
        ...         ("2", "C"), ("2", "B"), ("2", "A"),
        ...         ("3", "B"), ("3", "A"), ("3", "6"),
        ...         ("4", "C"), ("4", "B"), ("4", "A"),
        ...         ("5", "B"), ("5", "A"),
        ...         ("6", "5"),
        ...         ("A", "6")
        ...     ]
        ... )
        >>> c_graph, c_nodes = nx.dedensify(original_graph, threshold=2)
        >>> original_graph.number_of_edges()
        15
        >>> c_graph.number_of_edges()
        14
    A dedensified, directed graph can be "densified" to reconstruct the
    original graph::
        >>> original_graph = nx.DiGraph()
        >>> original_graph.add_nodes_from(
        ...     ["1", "2", "3", "4", "5", "6", "A", "B", "C"]
        ... )
        >>> original_graph.add_edges_from(
        ...     [
        ...         ("1", "C"), ("1", "B"),
        ...         ("2", "C"), ("2", "B"), ("2", "A"),
        ...         ("3", "B"), ("3", "A"), ("3", "6"),
        ...         ("4", "C"), ("4", "B"), ("4", "A"),
        ...         ("5", "B"), ("5", "A"),
        ...         ("6", "5"),
        ...         ("A", "6")
        ...     ]
        ... )
        >>> c_graph, c_nodes = nx.dedensify(original_graph, threshold=2)
        >>> # re-densifies the compressed graph into the original graph
        >>> for c_node in c_nodes:
        ...     all_neighbors = set(nx.all_neighbors(c_graph, c_node))
        ...     out_neighbors = set(c_graph.neighbors(c_node))
        ...     for out_neighbor in out_neighbors:
        ...         c_graph.remove_edge(c_node, out_neighbor)
        ...     in_neighbors = all_neighbors - out_neighbors
        ...     for in_neighbor in in_neighbors:
        ...         c_graph.remove_edge(in_neighbor, c_node)
        ...         for out_neighbor in out_neighbors:
        ...             c_graph.add_edge(in_neighbor, out_neighbor)
        ...     c_graph.remove_node(c_node)
        ...
        >>> nx.is_isomorphic(original_graph, c_graph)
        True

359: (4)                """Creates a summary graph based on attributes and connectivity.
360: (4)                This function uses the Summarization by Grouping Nodes on Attributes
361: (4)                and Pairwise edges (SNAP) algorithm for summarizing a given
362: (4)                graph by grouping nodes by node attributes and their edge attributes
363: (4)                into supernodes in a summary graph.  This name SNAP should not be
364: (4)                confused with the Stanford Network Analysis Project (SNAP).
365: (4)                Here is a high-level view of how this algorithm works:
366: (4)                1) Group nodes by node attribute values.
367: (4)                2) Iteratively split groups until all nodes in each group have edges
368: (4)                to nodes in the same groups. That is, until all the groups are homogeneous
369: (4)                in their member nodes' edges to other groups.  For example,
370: (4)                if all the nodes in group A only have edge to nodes in group B, then the
371: (4)                group is homogeneous and does not need to be split. If all nodes in group
B
372: (4)                have edges with nodes in groups {A, C}, but some also have edges with
other
373: (4)                nodes in B, then group B is not homogeneous and needs to be split into
374: (4)                groups have edges with {A, C} and a group of nodes having
375: (4)                edges with {A, B, C}.  This way, viewers of the summary graph can
376: (4)                assume that all nodes in the group have the exact same node attributes and
377: (4)                the exact same edges.
378: (4)                3) Build the output summary graph, where the groups are represented by
379: (4)                super-nodes. Edges represent the edges shared between all the nodes in
each
380: (4)                respective groups.
381: (4)                A SNAP summary graph can be used to visualize graphs that are too large to
display
382: (4)                or visually analyze, or to efficiently identify sets of similar nodes with
similar connectivity
383: (4)                patterns to other sets of similar nodes based on specified node and/or
edge attributes in a graph.
384: (4)                Parameters
385: (4)                ----------
386: (4)                G: graph
387: (8)                    Networkx Graph to be summarized
388: (4)                node_attributes: iterable, required
389: (8)                    An iterable of the node attributes used to group nodes in the
summarization process. Nodes
390: (8)                    with the same values for these attributes will be grouped together in
the summary graph.
391: (4)                edge_attributes: iterable, optional
392: (8)                    An iterable of the edge attributes considered in the summarization
process.  If provided, unique
393: (8)                    combinations of the attribute values found in the graph are used to
394: (8)                    determine the edge types in the graph.  If not provided, all edges
395: (8)                    are considered to be of the same type.
396: (4)                prefix: str
397: (8)                    The prefix used to denote supernodes in the summary graph. Defaults to
'Supernode-'.
```

```
    supernode_attribute: str
        The node attribute for recording the supernode groupings of nodes. Defaults to 'group'.
    superedge_attribute: str
        The edge attribute for recording the edge types of multiple edges. Defaults to 'types'.
    Returns
    -------
    networkx.Graph: summary graph
    Examples
    --------
    SNAP aggregation takes a graph and summarizes it in the context of user-provided
    node and edge attributes such that a viewer can more easily extract and
    analyze the information represented by the graph
    >>> nodes = {
    ...     "A": dict(color="Red"),
    ...     "B": dict(color="Red"),
    ...     "C": dict(color="Red"),
    ...     "D": dict(color="Red"),
    ...     "E": dict(color="Blue"),
    ...     "F": dict(color="Blue"),
    ... }
    >>> edges = [
    ...     ("A", "E", "Strong"),
    ...     ("B", "F", "Strong"),
    ...     ("C", "E", "Weak"),
    ...     ("D", "F", "Weak"),
    ... ]
    >>> G = nx.Graph()
    >>> for node in nodes:
    ...     attributes = nodes[node]
    ...     G.add_node(node, **attributes)
    >>> for source, target, type in edges:
    ...     G.add_edge(source, target, type=type)
    >>> node_attributes = ("color",)
    >>> edge_attributes = ("type",)
    >>> summary_graph = nx.snap_aggregation(
    ...     G, node_attributes=node_attributes, edge_attributes=edge_attributes
    ... )
    Notes
    -----
    The summary graph produced is called a maximum Attribute-edge
    compatible (AR-compatible) grouping.  According to [1]_, an
    AR-compatible grouping means that all nodes in each group have the same
    exact node attribute values and the same exact edges and
    edge types to one or more nodes in the same groups.  The maximal
    AR-compatible grouping is the grouping with the minimal cardinality.
    The AR-compatible grouping is the most detailed grouping provided by
    any of the SNAP algorithms.

(4)                 """Attempts the specified number of double-edge swaps in the graph `G`.
(4)                 A double-edge swap removes two randomly chosen edges `(u, v)` and `(x,
(4)                 y)` and creates the new edges `(u, x)` and `(v, y)`::
(5)                  u--v            u  v
(12)                        becomes  |  |
(5)                  x--y            x  y
(4)                 If either `(u, x)` or `(v, y)` already exist, then no swap is performed
(4)                 so the actual number of swapped edges is always *at most* `nswap`.
(4)                 Parameters
(4)                 ----------
(4)                 G : graph
(7)                    An undirected graph
(4)                 nswap : integer (optional, default=1)
(7)                    Number of double-edge swaps to perform
(4)                 _window_threshold : integer
(7)                    The window size below which connectedness of the graph will be checked
(7)                    after each swap.
(7)                    The "window" in this function is a dynamically updated integer that
(7)                    represents the number of swap attempts to make before checking if the
(7)                    graph remains connected. It is an optimization used to decrease the
(7)                    running time of the algorithm in exchange for increased complexity of
(7)                    implementation.
(7)                    If the window size is below this threshold, then the algorithm checks
(7)                    after each swap if the graph remains connected by checking if there is
a
(7)                    path joining the two nodes whose edge was just removed. If the window
(7)                    size is above this threshold, then the algorithm performs do all the
(7)                    swaps in the window and only then check if the graph is still
connected.
(4)                 seed : integer, random_state, or None (default)
(8)                     Indicator of random number generation state.
(8)                     See :ref:`Randomness<randomness>`.
(4)                 Returns
(4)                 -------
(4)                 int
(7)                    The number of successful swaps
(4)                 Raises
(4)                 ------
(4)                 NetworkXError
(7)                    If the input graph is not connected, or if the graph has fewer than
four
(7)                    nodes.
(4)                 Notes
(4)                 -----

(0)            ):
(4)                """
(4)                Returns a creation sequence for a threshold graph
(4)                determined by the weights and threshold given as input.
(4)                If the sum of two node weights is greater than the
(4)                threshold value, an edge is created between these nodes.
(4)                The creation sequence is a list of single characters 'd'
(4)                or 'i': 'd' for dominating or 'i' for isolated vertices.
(4)                Dominating vertices are connected to all vertices present
(4)                when it is added.  The first node added is by convention 'd'.
(4)                If with_labels==True:
(4)                Returns a list of 2-tuples containing the vertex number
(4)                and a character 'd' or 'i' which describes the type of vertex.
(4)                If compact==True:
(4)                Returns the creation sequence in a compact form that is the number
(4)                of 'i's and 'd's alternating.
(4)                Examples:
(4)                [1,2,2,3] represents d,i,i,d,d,i,i,i
(4)                [3,1,2] represents d,d,d,i,d,d
(4)                Notice that the first number is the first vertex to be used for
(4)                construction and so is always 'd'.
(4)                with_labels and compact cannot both be True.

14: (4)                 Parameters
```

```
15: (4)                 ----------
16: (4)                 G : graph
17: (7)                    A directed networkx graph whose nodes have `time` attributes and
optionally
18: (7)                    `weight` attributes (if a weight is not given, it is considered 1).
19: (4)                 node : node
20: (7)                    The node for which the CD index is calculated.
21: (4)                 time_delta : numeric or timedelta
22: (7)                    Amount of time after the `time` attribute of the `node`. The value of
23: (7)                    `time_delta` must support comparison with the `time` node attribute.
For
24: (7)                    example, if the `time` attribute of the nodes are `datetime.datetime`
25: (7)                    objects, then `time_delta` should be a `datetime.timedelta` object.
26: (4)                 time : string (Optional, default is "time")
27: (8)                     The name of the node attribute that will be used for the calculations.
28: (4)                 weight : string (Optional, default is None)
29: (8)                     The name of the node attribute used as weight.
30: (4)                 Returns
31: (4)                 -------
32: (4)                 float
33: (7)                    The CD index calculated for the node `node` within the graph `G`.
34: (4)                 Raises
35: (4)                 ------
36: (4)                 NetworkXError
37: (7)                    If not all nodes have a `time` attribute or
38: (7)                    `time_delta` and `time` attribute types are not compatible or
39: (7)                    `n` equals 0.
40: (4)                 NetworkXNotImplemented
41: (8)                     If `G` is a non-directed graph or a multigraph.
42: (4)                 Examples
43: (4)                 --------
44: (4)                 >>> from datetime import datetime, timedelta
45: (4)                 >>> G = nx.DiGraph()
46: (4)                 >>> nodes = {
47: (4)                 ...     1: {"time": datetime(2015, 1, 1)},
48: (4)                 ...     2: {"time": datetime(2012, 1, 1), "weight": 4},
49: (4)                 ...     3: {"time": datetime(2010, 1, 1)},
50: (4)                 ...     4: {"time": datetime(2008, 1, 1)},
51: (4)                 ...     5: {"time": datetime(2014, 1, 1)},
52: (4)                 ... }
53: (4)                 >>> G.add_nodes_from([(n, nodes[n]) for n in nodes])
54: (4)                 >>> edges = [(1, 3), (1, 4), (2, 3), (3, 4), (3, 5)]
55: (4)                 >>> G.add_edges_from(edges)
56: (4)                 >>> delta = timedelta(days=5 * 365)
57: (4)                 >>> nx.cd_index(G, 3, time_delta=delta, time="time")
58: (4)                 0.5
59: (4)                 >>> nx.cd_index(G, 3, time_delta=delta, time="time", weight="weight")
60: (4)                 0.12
61: (4)                 Integers can also be used for the time values:
62: (4)                 >>> node_times = {1: 2015, 2: 2012, 3: 2010, 4: 2008, 5: 2014}
63: (4)                 >>> nx.set_node_attributes(G, node_times, "new_time")
64: (4)                 >>> nx.cd_index(G, 3, time_delta=4, time="new_time")
65: (4)                 0.5
66: (4)                 >>> nx.cd_index(G, 3, time_delta=4, time="new_time", weight="weight")
67: (4)                 0.12
68: (4)                 Notes
69: (4)                 -----
70: (4)                 This method implements the algorithm for calculating the CD index,
71: (4)                 as described in the paper by Funk and Owen-Smith [1]_. The CD index
72: (4)                 is used in order to check how consolidating or destabilizing a patent
73: (4)                 is, hence the nodes of the graph represent patents and the edges show
74: (4)                 the citations between these patents. The mathematical model is given
75: (4)                 below:
76: (4)                 .. math::
77: (8)                     CD_{t}=\frac{1}{n_{t}}\sum_{i=1}^{n}\frac{-2f_{it}b_{it}+f_{it}}
{w_{it}},
78: (4)                 where `f_{it}` equals 1 if `i` cites the focal patent else 0, `b_{it}`
equals
79: (4)                 1 if `i` cites any of the focal patents successors else 0, `n_{t}` is the
```

```
number
80: (4)                 of forward citations in `i` and `w_{it}` is a matrix of weight for patent
`i`
81: (4)                 at time `t`.
82: (4)                 The `datetime.timedelta` package can lead to off-by-one issues when
converting
83: (4)                 from years to days. In the example above `timedelta(days=5 * 365)` looks
like
84: (4)                 5 years, but it isn't because of leap year days. So it gives the same
result
85: (4)                 as `timedelta(days=4 * 365)`. But using `timedelta(days=5 * 365 + 1)`
gives
86: (4)                 a 5 year delta **for this choice of years** but may not if the 5 year gap
has
87: (4)                 more than 1 leap year. To avoid these issues, use integers to represent
years,
88: (4)                 or be very careful when you convert units of time.

112: (4)                The triadic census is a count of how many of the 16 possible types of
113: (4)                triads are present in a directed graph. If a list of nodes is passed, then
114: (4)                only those triads are taken into account which have elements of nodelist
in them.
115: (4)                Parameters
```

```
    ----------
    G : digraph
       A NetworkX DiGraph
    nodelist : list
        List of nodes for which you want to calculate triadic census
    Returns
    -------
    census : dict
       Dictionary with triad type as keys and number of occurrences as values.
    Examples
    --------
    >>> G = nx.DiGraph([(1, 2), (2, 3), (3, 1), (3, 4), (4, 1), (4, 2)])
    >>> triadic_census = nx.triadic_census(G)
    >>> for key, value in triadic_census.items():
    ...     print(f"{key}: {value}")
    003: 0
    012: 0
    102: 0
    021D: 0
    021U: 0
    021C: 0
    111D: 0
    111U: 0
    030T: 2
    030C: 2
    201: 0
    120D: 0
    120U: 0
    120C: 0
    210: 0
    300: 0
    Notes
    -----
    This algorithm has complexity $O(m)$ where $m$ is the number of edges in
    the graph.
    For undirected graphs, the triadic census can be computed by first converting
    the graph into a directed graph using the ``G.to_directed()`` method.
    After this conversion, only the triad types 003, 102, 201 and 300 will be
    present in the undirected scenario.
    Raises
    ------
    ValueError
        If `nodelist` contains duplicate nodes or nodes not in `G`.
        If you want to ignore this you can preprocess with `set(nodelist) & G.nodes`
    See also

(4)                Notes
(4)                -----
```

```
379: (4)                There can be 6 unique edges in a triad (order-3 DiGraph) (so 2^^6=64
unique
380: (4)                triads given 3 nodes). These 64 triads each display exactly 1 of 16
381: (4)                topologies of triads (topologies can be permuted). These topologies are
382: (4)                identified by the following notation:
383: (4)                {m}{a}{n}{type} (for example: 111D, 210, 102)
384: (4)                Here:
385: (4)                {m}     = number of mutual ties (takes 0, 1, 2, 3); a mutual tie is (0,1)
386: (14)                         AND (1,0)
387: (4)                {a}     = number of asymmetric ties (takes 0, 1, 2, 3); an asymmetric tie
388: (14)                         is (0,1) BUT NOT (1,0) or vice versa
389: (4)                {n}     = number of null ties (takes 0, 1, 2, 3); a null tie is NEITHER
390: (14)                         (0,1) NOR (1,0)
391: (4)                {type}  = a letter (takes U, D, C, T) corresponding to up, down, cyclical
392: (14)                         and transitive. This is only used for topologies that can have
393: (14)                         more than one form (eg: 021D and 021U).
394: (4)                References

       random_triad is deprecated and will be removed in version 3.5.
       Use random sampling directly instead::
          G.subgraph(random.sample(list(G), 3))
    Parameters
    ----------
    G : digraph
       A NetworkX DiGraph
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
    Returns
    -------
    G2 : subgraph
       A randomly selected triad (order-3 NetworkX DiGraph)
    Raises
    ------
    NetworkXError
        If the input Graph has less than 3 nodes.
    Examples
    --------
    >>> G = nx.DiGraph([(1, 2), (1, 3), (2, 3), (3, 1), (5, 6), (5, 4), (6, 7)])
    >>> triad = nx.random_triad(G, seed=1)
    >>> triad.edges
    OutEdgeView([(1, 2)])
    """
    import warnings
    warnings.warn(

    """Returns the closeness vitality for nodes in the graph.
    The *closeness vitality* of a node, defined in Section 3.6.2 of [1],
    is the change in the sum of distances between all node pairs when
    excluding that node.
    Parameters
    ----------
    G : NetworkX graph
        A strongly-connected graph.
```

```
17: (4)                 weight : string
18: (8)                     The name of the edge attribute used as weight. This is passed
19: (8)                     directly to the :func:`~networkx.wiener_index` function.
20: (4)                 node : object
21: (8)                     If specified, only the closeness vitality for this node will be
22: (8)                     returned. Otherwise, a dictionary mapping each node to its
23: (8)                     closeness vitality will be returned.
24: (4)                 Other parameters
25: (4)                 ----------------
26: (4)                 wiener_index : number
27: (8)                     If you have already computed the Wiener index of the graph
28: (8)                     `G`, you can provide that value here. Otherwise, it will be
29: (8)                     computed for you.
30: (4)                 Returns
31: (4)                 -------
32: (4)                 dictionary or float
33: (8)                     If `node` is None, this function returns a dictionary
34: (8)                     with nodes as keys and closeness vitality as the
35: (8)                     value. Otherwise, it returns only the closeness vitality for the
36: (8)                     specified `node`.
37: (8)                     The closeness vitality of a node may be negative infinity if
38: (8)                     removing that node would disconnect the graph.
39: (4)                 Examples
40: (4)                 --------
41: (4)                 >>> G = nx.cycle_graph(3)

File 61 - voronoi.py:

1: (0)              """Functions for computing the Voronoi cells of a graph."""
2: (0)              import networkx as nx
3: (0)              from networkx.utils import groups
4: (0)              __all__ = ["voronoi_cells"]
5: (0)              @nx._dispatchable(edge_attrs="weight")
6: (0)              def voronoi_cells(G, center_nodes, weight="weight"):
7: (4)                  """Returns the Voronoi cells centered at `center_nodes` with respect
8: (4)                  to the shortest-path distance metric.
9: (4)                  If $C$ is a set of nodes in the graph and $c$ is an element of $C$,
10: (4)                 the *Voronoi cell* centered at a node $c$ is the set of all nodes
11: (4)                 $v$ that are closer to $c$ than to any other center node in $C$ with
12: (4)                 respect to the shortest-path distance metric. [1]_
13: (4)                 For directed graphs, this will compute the "outward" Voronoi cells,
14: (4)                 as defined in [1]_, in which distance is measured from the center
15: (4)                 nodes to the target node. For the "inward" Voronoi cells, use the
16: (4)                 :meth:`DiGraph.reverse` method to reverse the orientation of the
17: (4)                 edges before invoking this function on the directed graph.
18: (4)                 Parameters
19: (4)                 ----------
```

```
20: (4)                 G : NetworkX graph
21: (4)                 center_nodes : set
22: (8)                     A nonempty set of nodes in the graph `G` that represent the
23: (8)                     center of the Voronoi cells.
24: (4)                 weight : string or function
25: (8)                     The edge attribute (or an arbitrary function) representing the
26: (8)                     weight of an edge. This keyword argument is as described in the
27: (8)                     documentation for :func:`~networkx.multi_source_dijkstra_path`,
28: (8)                     for example.
29: (4)                 Returns
30: (4)                 -------
31: (4)                 dictionary
32: (8)                     A mapping from center node to set of all nodes in the graph
33: (8)                     closer to that center node than to any other center node. The
34: (8)                     keys of the dictionary are the element of `center_nodes`, and
35: (8)                     the values of the dictionary form a partition of the nodes of
36: (8)                     `G`.
37: (4)                 Examples
38: (4)                 --------
39: (4)                 To get only the partition of the graph induced by the Voronoi cells,
40: (4)                 take the collection of all values in the returned dictionary::

File 62 - walks.py:

```
1: (0)              """Function for computing walks in a graph.
2: (0)              """
3: (0)              import networkx as nx
4: (0)              __all__ = ["number_of_walks"]
5: (0)              @nx._dispatchable
6: (0)              def number_of_walks(G, walk_length):
7: (4)                  """Returns the number of walks connecting each pair of nodes in `G`
8: (4)                  A *walk* is a sequence of nodes in which each adjacent pair of nodes
9: (4)                  in the sequence is adjacent in the graph. A walk can repeat the same
10: (4)                 edge and go in the opposite direction just as people can walk on a
11: (4)                 set of paths, but standing still is not counted as part of the walk.
12: (4)                 This function only counts the walks with `walk_length` edges. Note that
13: (4)                 the number of nodes in the walk sequence is one more than `walk_length`.
14: (4)                 The number of walks can grow very quickly on a larger graph
15: (4)                 and with a larger walk length.
16: (4)                 Parameters
17: (4)                 ----------
18: (4)                 G : NetworkX graph
19: (4)                 walk_length : int
```

```
20: (8)                 A nonnegative integer representing the length of a walk.
21: (4)             Returns
22: (4)             -------
23: (4)             dict
24: (8)                 A dictionary of dictionaries in which outer keys are source
25: (8)                 nodes, inner keys are target nodes, and inner values are the
26: (8)                 number of walks of length `walk_length` connecting those nodes.
27: (4)             Raises
28: (4)             ------
29: (4)             ValueError
30: (8)                 If `walk_length` is negative
31: (4)             Examples
32: (4)             --------
33: (4)             >>> G = nx.Graph([(0, 1), (1, 2)])
34: (4)             >>> walks = nx.number_of_walks(G, 2)
35: (4)             >>> walks
36: (4)             {0: {0: 1, 1: 0, 2: 1}, 1: {0: 0, 1: 2, 2: 0}, 2: {0: 1, 1: 0, 2: 1}}
37: (4)             >>> total_walks = sum(sum(tgts.values()) for _, tgts in walks.items())
38: (4)             You can also get the number of walks from a specific source node using the
39: (4)             returned dictionary. For example, number of walks of length 1 from node 0
40: (4)             can be found as follows:
41: (4)             >>> walks = nx.number_of_walks(G, 1)
42: (4)             >>> walks[0]
43: (4)             {0: 0, 1: 1, 2: 0}
44: (4)             >>> sum(walks[0].values())  # walks from 0 of length 1
45: (4)             1
46: (4)             Similarly, a target node can also be specified:
47: (4)             >>> walks[0][1]
48: (4)             1
49: (4)             """
50: (4)             import numpy as np
51: (4)             if walk_length < 0:
52: (8)                 raise ValueError(f"`walk_length` cannot be negative: {walk_length}")
53: (4)             A = nx.adjacency_matrix(G, weight=None)
54: (4)             power = np.linalg.matrix_power(A.toarray(), walk_length)
55: (4)             result = {
56: (8)                 u: {v: power.item(u_idx, v_idx) for v_idx, v in enumerate(G)}
57: (8)                 for u_idx, u in enumerate(G)
58: (4)             }
59: (4)             return result
```

19: (0)         def wiener_index(G, weight=None):
20: (4)             """Returns the Wiener index of the given graph.
21: (4)             The *Wiener index* of a graph is the sum of the shortest-path
22: (4)             (weighted) distances between each pair of reachable nodes.
23: (4)             For pairs of nodes in undirected graphs, only one orientation
24: (4)             of the pair is counted.
```

```
 25: (4)                Parameters
 26: (4)                ----------
 27: (4)                G : NetworkX graph
 28: (4)                weight : string or None, optional (default: None)
 29: (8)                    If None, every edge has weight 1.
 30: (8)                    If a string, use this edge attribute as the edge weight.
 31: (8)                    Any edge attribute not present defaults to 1.
 32: (8)                    The edge weights are used to computing shortest-path distances.
 33: (4)                Returns
 34: (4)                -------
 35: (4)                number
 36: (8)                    The Wiener index of the graph `G`.
 37: (4)                Raises
 38: (4)                ------
 39: (4)                NetworkXError
 40: (8)                    If the graph `G` is not connected.
 41: (4)                Notes
 42: (4)                -----
 43: (4)                If a pair of nodes is not reachable, the distance is assumed to be
 44: (4)                infinity. This means that for graphs that are not
 45: (4)                strongly-connected, this function returns ``inf``.
 46: (4)                The Wiener index is not usually defined for directed graphs, however
 47: (4)                this function uses the natural generalization of the Wiener index to
 48: (4)                directed graphs.
 49: (4)                Examples
 50: (4)                --------
 51: (4)                The Wiener index of the (unweighted) complete graph on *n* nodes
 52: (4)                equals the number of pairs of the *n* nodes, since each pair of
 53: (4)                nodes is at distance one::
 54: (8)                    >>> n = 10
 55: (8)                    >>> G = nx.complete_graph(n)
 56: (8)                    >>> nx.wiener_index(G) == n * (n - 1) / 2
 57: (8)                    True
 58: (4)                Graphs that are not strongly-connected have infinite Wiener index::
 59: (8)                    >>> G = nx.empty_graph(2)
 60: (8)                    >>> nx.wiener_index(G)

43: (4)                 4
44: (4)                 Notes
45: (4)                 -----
46: (4)                 This algorithm [1]_ finds node independents paths between two nodes by
47: (4)                 computing their shortest path using BFS, marking the nodes of the path
48: (4)                 found as 'used' and then searching other shortest paths excluding the
49: (4)                 nodes marked as used until no more paths exist. It is not exact because
50: (4)                 a shortest path could use nodes that, if the path were longer, may belong
51: (4)                 to two different node independent paths. Thus it only guarantees an
52: (4)                 strict lower bound on node connectivity.
53: (4)                 Note that the authors propose a further refinement, losing accuracy and
54: (4)                 gaining speed, which is not implemented yet.

(4)                 Returns
(4)                 -------
(4)                 K : integer
(8)                     Node connectivity of G, or local node connectivity if source
(8)                     and target are provided.
(4)                 Examples
(4)                 --------
(4)                 >>> # Platonic octahedral graph is 4-node-connected
(4)                 >>> from networkx.algorithms import approximation as approx
(4)                 >>> G = nx.octahedral_graph()
(4)                 >>> approx.node_connectivity(G)
(4)                 4
(4)                 Notes
(4)                 -----
(4)                 This algorithm [1]_ finds node independents paths between two nodes by
(4)                 computing their shortest path using BFS, marking the nodes of the path
(4)                 found as 'used' and then searching other shortest paths excluding the
(4)                 nodes marked as used until no more paths exist. It is not exact because
(4)                 a shortest path could use nodes that, if the path were longer, may belong
(4)                 to two different node independent paths. Thus it only guarantees an
(4)                 strict lower bound on node connectivity.

(4)             """Compute node connectivity between all pairs of nodes.
(4)             Pairwise or local node connectivity between two distinct and nonadjacent
(4)             nodes is the minimum number of nodes that must be removed (minimum
(4)             separating cutset) to disconnect them. By Menger's theorem, this is equal
(4)             to the number of node independent paths (paths that share no nodes other
(4)             than source and target). Which is what we compute in this function.
(4)             This algorithm is a fast approximation that gives an strict lower
(4)             bound on the actual number of node independent paths between two nodes
[1]_.
(4)             It works for both directed and undirected graphs.
(4)             Parameters
(4)             ----------
(4)             G : NetworkX graph
(4)             nbunch: container
(8)                 Container of nodes. If provided node connectivity will be computed
(8)                 only over pairs of nodes in nbunch.
(4)             cutoff : integer
(8)                 Maximum node connectivity to consider. If None, the minimum degree
(8)                 of source or target is used as a cutoff in each pair of nodes.
(8)                 Default value None.
(4)             Returns
(4)             -------
(4)             K : dictionary
(8)                 Dictionary, keyed by source and target, of pairwise node connectivity
(4)             Examples
(4)             --------
(4)             A 3 node cycle with one extra node attached has connectivity 2 between all
(4)             nodes in the cycle and connectivity 1 between the extra node and the rest:
(4)             >>> G = nx.cycle_graph(3)
(4)             >>> G.add_edge(2, 3)
(4)             >>> import pprint  # for nice dictionary formatting
(4)             >>> pprint.pprint(nx.all_pairs_node_connectivity(G))
(4)             {0: {1: 2, 2: 2, 3: 1},
(5)              1: {0: 2, 2: 2, 3: 1},

30: (8)                     A set of nodes, the sum of whose weights is no more than `(\log
31: (8)                     w(V)) w(V^*)`, where `w(V)` denotes the sum of the weights of
32: (8)                     each node in the graph and `w(V^*)` denotes the sum of the
33: (8)                     weights of each node in the minimum weight dominating set.
34: (4)                 Examples
```

```
    --------
    >>> G = nx.Graph([(0, 1), (0, 4), (1, 4), (1, 2), (2, 3), (3, 4), (2, 5)])
    >>> nx.approximation.min_weighted_dominating_set(G)
    {1, 2, 4}
    Raises
    ------
    NetworkXNotImplemented
        If G is directed.
    Notes
    -----
    This algorithm computes an approximate minimum weighted dominating
    set for the graph `G`. The returned solution has weight `(\log
    w(V)) w(V^*)`, where `w(V)` denotes the sum of the weights of each
    node in the graph and `w(V^*)` denotes the sum of the weights of
    each node in the minimum weight dominating set for the graph.
    This implementation of the algorithm runs in $O(m)$ time, where $m$
    is the number of edges in the graph.

__all__ = ["k_components"]
@not_implemented_for("directed")
@nx._dispatchable(name="approximate_k_components")
def k_components(G, min_density=0.95):
    r"""Returns the approximate k-component structure of a graph G.
    A `k`-component is a maximal subgraph of a graph G that has, at least,
    node connectivity `k`: we need to remove at least `k` nodes to break it
    into more components. `k`-components have an inherent hierarchical
    structure because they are nested in terms of connectivity: a connected
    graph can contain several 2-components, each of which can contain
    one or more 3-components, and so forth.
    This implementation is based on the fast heuristics to approximate
    the `k`-component structure of a graph [1]_. Which, in turn, it is based
on
    a fast approximation algorithm for finding good lower bounds of the number
    of node independent paths between two nodes [2]_.
    Parameters
    ----------
    G : NetworkX graph
        Undirected graph
    min_density : Float
        Density relaxation threshold. Default value 0.95
    Returns
    -------
    k_components : dict
        Dictionary with connectivity level `k` as key and a list of
        sets of nodes that form a k-component of level `k` as values.
    Raises
    ------
    NetworkXNotImplemented
        If G is directed.
    Examples
    --------
    >>> # Petersen graph has 10 nodes and it is triconnected, thus all
    >>> # nodes are in a single component on all three connectivity levels
    >>> from networkx.algorithms import approximation as apxa
    >>> G = nx.petersen_graph()
    >>> k_components = apxa.k_components(G)
    Notes
    -----
    The logic of the approximation algorithm for computing the `k`-component
    structure [1]_ is based on repeatedly applying simple and fast algorithms
    for `k`-cores and biconnected components in order to narrow down the
    number of pairs of nodes over which we have to compute White and Newman's
    approximation algorithm for finding node independent paths [2]_. More
    formally, this algorithm is based on Whitney's theorem, which states
    an inclusion relation among node connectivity, edge connectivity, and
    minimum degree for any graph G. This theorem implies that every
    `k`-component is nested inside a `k`-edge-component, which in turn,
    is contained in a `k`-core. Thus, this algorithm computes node independent
    paths among pairs of nodes in each biconnected part of each `k`-core,
    and repeats this procedure for each `k` from 3 to the maximal core number
    of a node in the input graph.
    Because, in practice, many nodes of the core of level `k` inside a
    bicomponent actually are part of a component of level k, the auxiliary
    graph needed for the algorithm is likely to be very dense. Thus, we use
    a complement graph data structure (see `AntiGraph`) to save memory.
    AntiGraph only stores information of the edges that are *not* present
    in the actual auxiliary graph. When applying algorithms to this
    complement graph data structure, it behaves as if it were the dense
    version.

    """Compute a random partitioning of the graph nodes and its cut value.
    A partitioning is calculated by observing each node
    and deciding to add it to the partition with probability `p`,
    returning a random cut and its corresponding value (the
    sum of weights of edges connecting different partitions).
    Parameters
    ----------
    G : NetworkX graph
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
    p : scalar
        Probability for each node to be part of the first partition.
        Should be in [0,1]
    weight : object
        Edge attribute key to use as weight. If not specified, edges
        have weight one.
    Returns
    -------
    cut_size : scalar
        Value of the minimum cut.
    partition : pair of node sets
        A partitioning of the nodes that defines a minimum cut.
    Examples
    --------
    >>> G = nx.complete_graph(5)
    >>> cut_size, partition = nx.approximation.randomized_partitioning(G, seed=1)

    >>> cut_size
    6
    >>> partition
    ({0, 3, 4}, {1, 2})
    Raises
    ------
    NetworkXNotImplemented
        If the graph is directed or is a multigraph.

91: (4)                 r"""Return an approximation to the minimum Steiner tree of a graph.
92: (4)                 The minimum Steiner tree of `G` w.r.t a set of `terminal_nodes` (also *S*)
93: (4)                 is a tree within `G` that spans those nodes and has minimum size (sum of
94: (4)                 edge weights) among all such trees.
95: (4)                 The approximation algorithm is specified with the `method` keyword
96: (4)                 argument. All three available algorithms produce a tree whose weight is
97: (4)                 within a ``(2 - (2 / l))`` factor of the weight of the optimal Steiner
tree,
98: (4)                 where ``l`` is the minimum number of leaf nodes across all possible
Steiner
99: (4)                 trees.
100: (4)                * ``"kou"`` [2]_ (runtime $O(|S| |V|^2)$) computes the minimum spanning
tree of
101: (6)                  the subgraph of the metric closure of *G* induced by the terminal nodes,
102: (6)                  where the metric closure of *G* is the complete graph in which each edge
is
103: (6)                  weighted by the shortest path distance between the nodes in *G*.
104: (4)                * ``"mehlhorn"`` [3]_ (runtime $O(|E|+|V|\log|V|)$) modifies Kou et al.'s
105: (6)                  algorithm, beginning by finding the closest terminal node for each
106: (6)                  non-terminal. This data is used to create a complete graph containing
only
107: (6)                  the terminal nodes, in which edge is weighted with the shortest path
```

```
108: (6)                  distance between them. The algorithm then proceeds in the same way as
Kou
109: (6)                  et al..
110: (4)                Parameters
111: (4)                ----------

2: (0)              ================================
3: (0)              Travelling Salesman Problem (TSP)
4: (0)              ================================
```

```
5: (0)              Implementation of approximate algorithms
6: (0)              for solving and approximating the TSP problem.
7: (0)              Categories of algorithms which are implemented:
8: (0)              - Christofides (provides a 3/2-approximation of TSP)
9: (0)              - Greedy
10: (0)             - Simulated Annealing (SA)
11: (0)             - Threshold Accepting (TA)
12: (0)             - Asadpour Asymmetric Traveling Salesman Algorithm
13: (0)             The Travelling Salesman Problem tries to find, given the weight
14: (0)             (distance) between all points where a salesman has to visit, the
15: (0)             route so that:
16: (0)             - The total distance (cost) which the salesman travels is minimized.
17: (0)             - The salesman returns to the starting point.
18: (0)             - Note that for a complete graph, the salesman visits each point once.
19: (0)             The function `travelling_salesman_problem` allows for incomplete
20: (0)             graphs by finding all-pairs shortest paths, effectively converting
21: (0)             the problem to a complete graph problem. It calls one of the
22: (0)             approximate methods on that problem and then converts the result
23: (0)             back to the original graph using the previously found shortest paths.
24: (0)             TSP is an NP-hard problem in combinatorial optimization,
25: (0)             important in operations research and theoretical computer science.

157: (0)            @nx._dispatchable(edge_attrs="weight")
158: (0)            def traveling_salesman_problem(
159: (4)                G, weight="weight", nodes=None, cycle=True, method=None, **kwargs
160: (0)            ):
161: (4)                """Find the shortest path in `G` connecting specified nodes
162: (4)                This function allows approximate solution to the traveling salesman
163: (4)                problem on networks that are not complete graphs and/or where the
164: (4)                salesman does not need to visit all nodes.
165: (4)                This function proceeds in two steps. First, it creates a complete
166: (4)                graph using the all-pairs shortest_paths between nodes in `nodes`.
167: (4)                Edge weights in the new graph are the lengths of the paths
168: (4)                between each pair of nodes in the original graph.
169: (4)                Second, an algorithm (default: `christofides` for undirected and
170: (4)                `asadpour_atsp` for directed) is used to approximate the minimal
Hamiltonian
171: (4)                cycle on this new graph. The available algorithms are:
172: (5)                 - christofides
173: (5)                 - greedy_tsp
174: (5)                 - simulated_annealing_tsp
175: (5)                 - threshold_accepting_tsp
176: (5)                 - asadpour_atsp
177: (4)                Once the Hamiltonian Cycle is found, this function post-processes to
178: (4)                accommodate the structure of the original graph. If `cycle` is ``False``,
179: (4)                the biggest weight edge is removed to make a Hamiltonian path.
180: (4)                Then each edge on the new complete graph used for that analysis is
181: (4)                replaced by the shortest_path between those nodes on the original graph.
182: (4)                If the input graph `G` includes edges with weights that do not adhere to
183: (4)                the triangle inequality, such as when `G` is not a complete graph (i.e
184: (4)                length of non-existent edges is infinity), then the returned path may
185: (4)                contain some repeating nodes (other than the starting node).
186: (4)                Parameters
187: (4)                ----------
188: (4)                G : NetworkX graph
189: (8)                    A possibly weighted graph
190: (4)                nodes : collection of nodes (default=G.nodes)
191: (8)                    collection (list, set, etc.) of nodes to visit
192: (4)                weight : string, optional (default="weight")
193: (8)                    Edge data key corresponding to the edge weight.
194: (8)                    If any edge does not have this attribute the weight is set to 1.
195: (4)                cycle : bool (default: True)
196: (8)                    Indicates whether a cycle should be returned, or a path.
197: (8)                    Note: the cycle is the approximate minimal cycle.
198: (8)                    The path simply removes the biggest edge in that cycle.
199: (4)                method : function (default: None)
200: (8)                    A function that returns a cycle on all nodes and approximates
201: (8)                    the solution to the traveling salesman problem on a complete
202: (8)                    graph. The returned cycle is then used to find a corresponding
203: (8)                    solution on `G`. `method` should be callable; take inputs
204: (8)                    `G`, and `weight`; and return a list of nodes along the cycle.
205: (8)                    Provided options include :func:`christofides`, :func:`greedy_tsp`,
206: (8)                    :func:`simulated_annealing_tsp` and :func:`threshold_accepting_tsp`.
207: (8)                    If `method is None`: use :func:`christofides` for undirected `G` and
208: (8)                    :func:`asadpour_atsp` for directed `G`.
209: (4)                **kwargs : dict
210: (8)                    Other keyword arguments to be passed to the `method` function passed
```

```
in.
    Returns
    -------
    list
        List of nodes in `G` along a path with an approximation of the minimal
        path through `nodes`.
    Raises
    ------
    NetworkXError
        If `G` is a directed graph it has to be strongly connected or the
        complete version cannot be generated.
    Examples
    --------
    >>> tsp = nx.approximation.traveling_salesman_problem
    >>> G = nx.cycle_graph(9)
    >>> G[4][5]["weight"] = 5  # all other weights are 1
    >>> tsp(G, nodes=[3, 6])
    [3, 2, 1, 0, 8, 7, 6, 7, 8, 0, 1, 2, 3]
    >>> path = tsp(G, cycle=False)
    >>> path in ([4, 3, 2, 1, 0, 8, 7, 6, 5], [5, 6, 7, 8, 0, 1, 2, 3, 4])
    True
    While no longer required, you can still build (curry) your own function
    to provide parameter values to the methods.
    >>> SA_tsp = nx.approximation.simulated_annealing_tsp
    >>> method = lambda G, weight: SA_tsp(G, "greedy", weight=weight,
temp=500)
    >>> path = tsp(G, cycle=False, method=method)
    >>> path in ([4, 3, 2, 1, 0, 8, 7, 6, 5], [5, 6, 7, 8, 0, 1, 2, 3, 4])
    True
    Otherwise, pass other keyword arguments directly into the tsp function.
    >>> path = tsp(
    ...     G,
    ...     cycle=False,
    ...     method=nx.approximation.simulated_annealing_tsp,
    ...     init_cycle="greedy",
    ...     temp=500,
    ... )
    >>> path in ([4, 3, 2, 1, 0, 8, 7, 6, 5], [5, 6, 7, 8, 0, 1, 2, 3, 4])
    True
    """

(4)                Minimizes the Held-Karp relaxation of the TSP for `G`
(4)                Solves the Held-Karp relaxation of the input complete digraph and scales
(4)                the output solution for use in the Asadpour [1]_ ASTP algorithm.
(4)                The Held-Karp relaxation defines the lower bound for solutions to the
(4)                ATSP, although it does return a fractional solution. This is used in the
(4)                Asadpour algorithm as an initial solution which is later rounded to a
(4)                integral tree within the spanning tree polytopes. This function solves
(4)                the relaxation with the branch and bound method in [2]_.
(4)                Parameters
(4)                ----------
```

```
    G : nx.DiGraph
        The graph should be a complete weighted directed graph.
        The distance between all paris of nodes should be included.
    weight : string, optional (default="weight")
        Edge data key corresponding to the edge weight.
        If any edge does not have this attribute the weight is set to 1.
    Returns
    -------
    OPT : float
        The cost for the optimal solution to the Held-Karp relaxation
    z : dict or nx.Graph
        A symmetrized and scaled version of the optimal solution to the
        Held-Karp relaxation for use in the Asadpour algorithm.
        If an integral solution is found, then that is an optimal solution for
        the ATSP problem and that is returned instead.

    """
    Find the asadpour exponential distribution of spanning trees.
    Solves the Maximum Entropy Convex Program in the Asadpour algorithm [1]_
    using the approach in section 7 to build an exponential distribution of
    undirected spanning trees.
    This algorithm ensures that the probability of any edge in a spanning
    tree is proportional to the sum of the probabilities of the tress
    containing that edge over the sum of the probabilities of all spanning
    trees of the graph.
    Parameters
    ----------
    G : nx.MultiGraph
        The undirected support graph for the Held Karp relaxation
    z : dict
        The output of `held_karp_ascent()`, a scaled version of the Held-Karp
        solution.
    Returns
    -------
    gamma : dict
        The probability distribution which approximately preserves the marginal
        probabilities of `z`.
    """

(0)             def greedy_tsp(G, weight="weight", source=None):
(4)                 """Return a low cost cycle starting at `source` and its cost.
(4)                 This approximates a solution to the traveling salesman problem.
(4)                 It finds a cycle of all the nodes that a salesman can visit in order
(4)                 to visit many nodes while minimizing total distance.
(4)                 It uses a simple greedy algorithm.
(4)                 In essence, this function returns a large cycle given a source point
(4)                 for which the total cost of the cycle is minimized.
(4)                 Parameters
(4)                 ----------
(4)                 G : Graph
(8)                     The Graph should be a complete weighted undirected graph.
(8)                     The distance between all pairs of nodes should be included.
(4)                 weight : string, optional (default="weight")
(8)                     Edge data key corresponding to the edge weight.
(8)                     If any edge does not have this attribute the weight is set to 1.
(4)                 source : node, optional (default: first node in list(G))
(8)                     Starting node.  If None, defaults to ``next(iter(G))``
(4)                 Returns
(4)                 -------
(4)                 cycle : list of nodes
(8)                     Returns the cycle (list of nodes) that a salesman
(8)                     can follow to minimize total weight of the trip.
(4)                 Raises
(4)                 ------
(4)                 NetworkXError
(8)                     If `G` is not complete, the algorithm raises an exception.
(4)                 Examples
(4)                 --------
(4)                 >>> from networkx.algorithms import approximation as approx
(4)                 >>> G = nx.DiGraph()
(4)                 >>> G.add_weighted_edges_from(
(4)                 ...     {
(4)                 ...         ("A", "B", 3),
(4)                 ...         ("A", "C", 17),
(4)                 ...         ("A", "D", 14),
(4)                 ...         ("B", "A", 3),
(4)                 ...         ("B", "C", 12),
(4)                 ...         ("B", "D", 16),
(4)                 ...         ("C", "A", 13),
(4)                 ...         ("C", "B", 12),
(4)                 ...         ("C", "D", 4),
(4)                 ...         ("D", "A", 14),
(4)                 ...         ("D", "B", 15),
(4)                 ...         ("D", "C", 2),
(4)                 ...     }

793: (4)                """Returns an approximate solution to the traveling salesman problem.
794: (4)                This function uses simulated annealing to approximate the minimal cost
795: (4)                cycle through the nodes. Starting from a suboptimal solution, simulated
796: (4)                annealing perturbs that solution, occasionally accepting changes that make
797: (4)                the solution worse to escape from a locally optimal solution. The chance
798: (4)                of accepting such changes decreases over the iterations to encourage
799: (4)                an optimal result.  In summary, the function returns a cycle starting
800: (4)                at `source` for which the total cost is minimized. It also returns the
cost.
801: (4)                The chance of accepting a proposed change is related to a parameter called
802: (4)                the temperature (annealing has a physical analogue of steel hardening
803: (4)                as it cools). As the temperature is reduced, the chance of moves that
804: (4)                increase cost goes down.
805: (4)                Parameters
806: (4)                ----------
807: (4)                G : Graph
808: (8)                    `G` should be a complete weighted graph.
809: (8)                    The distance between all pairs of nodes should be included.
```

```
(4)                 init_cycle : list of all nodes or "greedy"
(8)                     The initial solution (a cycle through all nodes returning to the start).
(8)                     This argument has no default to make you think about it.
(8)                     If "greedy", use `greedy_tsp(G, weight)`.
(8)                     Other common starting cycles are `list(G) + [next(iter(G))]` or the final
(8)                     result of `simulated_annealing_tsp` when doing `threshold_accepting_tsp`.
(4)                 weight : string, optional (default="weight")
(8)                     Edge data key corresponding to the edge weight.
(8)                     If any edge does not have this attribute the weight is set to 1.
(4)                 source : node, optional (default: first node in list(G))
(8)                     Starting node.  If None, defaults to ``next(iter(G))``
(4)                 temp : int, optional (default=100)
(8)                     The algorithm's temperature parameter. It represents the initial
(8)                     value of temperature
(4)                 move : "1-1" or "1-0" or function, optional (default="1-1")
(8)                     Indicator of what move to use when finding new trial solutions.
(8)                     Strings indicate two special built-in moves:
(8)                     - "1-1": 1-1 exchange which transposes the position
(10)                      of two elements of the current solution.
(10)                      The function called is :func:`swap_two_nodes`.
(10)                      For example if we apply 1-1 exchange in the solution
(10)                      ``A = [3, 2, 1, 4, 3]``
(10)                      we can get the following by the transposition of 1 and 4 elements:
(10)                      ``A' = [3, 2, 4, 1, 3]``
(8)                     - "1-0": 1-0 exchange which moves an node in the solution
(10)                      to a new position.
(10)                      The function called is :func:`move_one_node`.
(10)                      For example if we apply 1-0 exchange in the solution
(10)                      ``A = [3, 2, 1, 4, 3]``
(10)                      we can transfer the fourth element to the second position:
(10)                      ``A' = [3, 4, 2, 1, 3]``
(8)                     You may provide your own functions to enact a move from
(8)                     one solution to a neighbor solution. The function must take
(8)                     the solution as input along with a `seed` input to control
(8)                     random number generation (see the `seed` input here).
(8)                     Your function should maintain the solution as a cycle with
(8)                     equal first and last node and all others appearing once.
(8)                     Your function should return the new solution.
(4)                 max_iterations : int, optional (default=10)
(8)                     Declared done when this number of consecutive iterations of
(8)                     the outer loop occurs without any change in the best cost solution.
(4)                 N_inner : int, optional (default=100)
(8)                     The number of iterations of the inner loop.
(4)                 alpha : float between (0, 1), optional (default=0.01)
(8)                     Percentage of temperature decrease in each iteration
(8)                     of outer loop
(4)                 seed : integer, random_state, or None (default)
(8)                     Indicator of random number generation state.
(8)                     See :ref:`Randomness<randomness>`.
(4)                 Returns
(4)                 -------
(4)                 cycle : list of nodes
(8)                     Returns the cycle (list of nodes) that a salesman
(8)                     can follow to minimize total weight of the trip.
(4)                 Raises
(4)                 ------
(4)                 NetworkXError
(8)                     If `G` is not complete the algorithm raises an exception.
(4)                 Examples
(4)                 --------
(4)                 >>> from networkx.algorithms import approximation as approx
(4)                 >>> G = nx.DiGraph()

(4)                 31
(4)                 Notes
(4)                 -----
(4)                 Simulated Annealing is a metaheuristic local search algorithm.
(4)                 The main characteristic of this algorithm is that it accepts
(4)                 even solutions which lead to the increase of the cost in order
(4)                 to escape from low quality local optimal solutions.
(4)                 This algorithm needs an initial solution. If not provided, it is
(4)                 constructed by a simple greedy algorithm. At every iteration, the
(4)                 algorithm selects thoughtfully a neighbor solution.
(4)                 Consider $c(x)$ cost of current solution and $c(x')$ cost of a
(4)                 neighbor solution.
(4)                 If $c(x') - c(x) <= 0$ then the neighbor solution becomes the current
(4)                 solution for the next iteration. Otherwise, the algorithm accepts
(4)                 the neighbor solution with probability $p = exp - ([c(x') - c(x)] /
temp)$.
(4)                 Otherwise the current solution is retained.
(4)                 `temp` is a parameter of the algorithm and represents temperature.
(4)                 Time complexity:
(4)                 For $N_i$ iterations of the inner loop and $N_o$ iterations of the
(4)                 outer loop, this algorithm has running time $O(N_i * N_o * |V|)$.
(4)                 For more information and how the algorithm is inspired see:

(4)                 """Returns an approximate solution to the traveling salesman problem.
(4)                 This function uses threshold accepting methods to approximate the minimal
cost
(4)                 cycle through the nodes. Starting from a suboptimal solution, threshold
(4)                 accepting methods perturb that solution, accepting any changes that make
(4)                 the solution no worse than increasing by a threshold amount. Improvements
(4)                 in cost are accepted, but so are changes leading to small increases in
cost.
(4)                 This allows the solution to leave suboptimal local minima in solution
space.
(4)                 The threshold is decreased slowly as iterations proceed helping to ensure
(4)                 an optimum. In summary, the function returns a cycle starting at `source`
(4)                 for which the total cost is minimized.
(4)                 Parameters
(4)                 ----------
(4)                 G : Graph
(8)                     `G` should be a complete weighted graph.
(8)                     The distance between all pairs of nodes should be included.
(4)                 init_cycle : list or "greedy"
(8)                     The initial solution (a cycle through all nodes returning to the
start).
(8)                     This argument has no default to make you think about it.
(8)                     If "greedy", use `greedy_tsp(G, weight)`.
```

```
(8)                 Other common starting cycles are `list(G) + [next(iter(G))]` or the final
(8)                 result of `simulated_annealing_tsp` when doing `threshold_accepting_tsp`.
(4)             weight : string, optional (default="weight")
(8)                 Edge data key corresponding to the edge weight.
(8)                 If any edge does not have this attribute the weight is set to 1.
(4)             source : node, optional (default: first node in list(G))
(8)                 Starting node.  If None, defaults to ``next(iter(G))``
(4)             threshold : int, optional (default=1)
(8)                 The algorithm's threshold parameter. It represents the initial
(8)                 threshold's value
(4)             move : "1-1" or "1-0" or function, optional (default="1-1")
(8)                 Indicator of what move to use when finding new trial solutions.
(8)                 Strings indicate two special built-in moves:
(8)                 - "1-1": 1-1 exchange which transposes the position
(10)                  of two elements of the current solution.
(10)                  The function called is :func:`swap_two_nodes`.
(10)                  For example if we apply 1-1 exchange in the solution
(10)                  ``A = [3, 2, 1, 4, 3]``
(10)                  we can get the following by the transposition of 1 and 4 elements:
(10)                  ``A' = [3, 2, 4, 1, 3]``
(8)                 - "1-0": 1-0 exchange which moves an node in the solution
(10)                  to a new position.
(10)                  The function called is :func:`move_one_node`.
(10)                  For example if we apply 1-0 exchange in the solution
(10)                  ``A = [3, 2, 1, 4, 3]``
(10)                  we can transfer the fourth element to the second position:
(10)                  ``A' = [3, 4, 2, 1, 3]``
(8)                 You may provide your own functions to enact a move from
(8)                 one solution to a neighbor solution. The function must take
(8)                 the solution as input along with a `seed` input to control
(8)                 random number generation (see the `seed` input here).
(8)                 Your function should maintain the solution as a cycle with
(8)                 equal first and last node and all others appearing once.
(8)                 Your function should return the new solution.
(4)             max_iterations : int, optional (default=10)
(8)                 Declared done when this number of consecutive iterations of
(8)                 the outer loop occurs without any change in the best cost solution.
(4)             N_inner : int, optional (default=100)
(8)                 The number of iterations of the inner loop.
(4)             alpha : float between (0, 1), optional (default=0.1)
(8)                 Percentage of threshold decrease when there is at
(8)                 least one acceptance of a neighbor solution.
(8)                 If no inner loop moves are accepted the threshold remains unchanged.
(4)             seed : integer, random_state, or None (default)
(8)                 Indicator of random number generation state.
(8)                 See :ref:`Randomness<randomness>`.
(4)             Returns
(4)             -------
(4)             cycle : list of nodes
(8)                 Returns the cycle (list of nodes) that a salesman
(8)                 can follow to minimize total weight of the trip.
(4)             Raises
(4)             ------
(4)             NetworkXError
(8)                 If `G` is not complete the algorithm raises an exception.
(4)             Examples
(4)             --------
(4)             >>> from networkx.algorithms import approximation as approx
(4)             >>> G = nx.DiGraph()
(4)             >>> G.add_weighted_edges_from(
(4)             ...     {
(4)             ...         ("A", "B", 3),
(4)             ...         ("A", "C", 17),
(4)             ...         ("A", "D", 14),
(4)             ...         ("B", "A", 3),
(4)             ...         ("B", "C", 12),
(4)             ...         ("B", "D", 16),
```

```
(4)                 ...         ("C", "A", 13),
(4)                 ...         ("C", "B", 12),
(4)                 ...         ("C", "D", 4),
(4)                 ...         ("D", "A", 14),
(4)                 ...         ("D", "B", 15),
(4)                 ...         ("D", "C", 2),
(4)                 ...     }
(4)                 ... )
(4)                 >>> cycle = approx.threshold_accepting_tsp(G, "greedy", source="D")
(4)                 >>> cost = sum(G[n][nbr]["weight"] for n, nbr in nx.utils.pairwise(cycle))
(4)                 >>> cycle
(4)                 ['D', 'C', 'B', 'A', 'D']
(4)                 >>> cost
(4)                 31
(4)                 >>> incycle = ["D", "B", "A", "C", "D"]
(4)                 >>> cycle = approx.threshold_accepting_tsp(G, incycle, source="D")
(4)                 >>> cost = sum(G[n][nbr]["weight"] for n, nbr in nx.utils.pairwise(cycle))
(4)                 >>> cycle
(4)                 ['D', 'C', 'B', 'A', 'D']
(4)                 >>> cost
(4)                 31
(4)                 Notes
(4)                 -----
(4)                 Threshold Accepting is a metaheuristic local search algorithm.
(4)                 The main characteristic of this algorithm is that it accepts
(4)                 even solutions which lead to the increase of the cost in order
(4)                 to escape from low quality local optimal solutions.
(4)                 This algorithm needs an initial solution. This solution can be
(4)                 constructed by a simple greedy algorithm. At every iteration, it
(4)                 selects thoughtfully a neighbor solution.
(4)                 Consider $c(x)$ cost of current solution and $c(x')$ cost of
(4)                 neighbor solution.
(4)                 If $c(x') - c(x) <= threshold$ then the neighbor solution becomes the
current
(4)                 solution for the next iteration, where the threshold is named threshold.
(4)                 In comparison to the Simulated Annealing algorithm, the Threshold
(4)                 Accepting algorithm does not accept very low quality solutions
(4)                 (due to the presence of the threshold value). In the case of
(4)                 Simulated Annealing, even a very low quality solution can
(4)                 be accepted with probability $p$.
(4)                 Time complexity:
(4)                 It has a running time $O(m * n * |V|)$ where $m$ and $n$ are the number
(4)                 of times the outer and inner loop run respectively.
(4)                 For more information and how algorithm is inspired see:
(4)                 https://doi.org/10.1016/0021-9991(90)90201-B

```

```
nodes=None):
    """Compute degree assortativity of graph.
    Assortativity measures the similarity of connections
    in the graph with respect to the node degree.
    This is the same as degree_assortativity_coefficient but uses the
    potentially faster scipy.stats.pearsonr function.
    Parameters
    ----------
    G : NetworkX graph
    x: string ('in','out')
       The degree type for source node (directed graphs only).
    y: string ('in','out')
       The degree type for target node (directed graphs only).
    weight: string or None, optional (default=None)
       The edge attribute that holds the numerical value used
       as a weight.  If None, then each edge has weight 1.
       The degree is the sum of the edge weights adjacent to the node.
    nodes: list or iterable (optional)
        Compute pearson correlation of degrees only for specified nodes.
        The default is all nodes.
    Returns
    -------
    r : float
       Assortativity of graph by degree.
    Examples
    --------
    >>> G = nx.path_graph(4)
    >>> r = nx.degree_pearson_correlation_coefficient(G)
    >>> print(f"{r:3.1f}")
    -0.5
    Notes
    -----
    This calls scipy.stats.pearsonr.

    """Returns mixing matrix for attribute.
    Parameters
    ----------
    G : graph
       NetworkX graph object.
    attribute : string
       Node attribute key.
    nodes: list or iterable (optional)
        Use only nodes in container to build the matrix. The default is
        all nodes.
    mapping : dictionary, optional
       Mapping from node attribute to integer index in matrix.
       If not specified, an arbitrary ordering will be used.
    normalized : bool (default=True)
       Return counts if False or probabilities if True.
    Returns
    -------
    m: numpy array
       Counts or joint probability of occurrence of attribute pairs.
    Notes
    -----
    If each node has a unique attribute value, the unnormalized mixing matrix
    will be equal to the adjacency matrix. To get a denser mixing matrix,
    the rounding can be performed to form groups of nodes with equal values.
    For example, the exact height of persons in cm (180.79155222, 163.9080892,
    163.30095355, 167.99016217, 168.21590163, ...) can be rounded to (180, 163,
    163, 168, 168, ...).
    Definitions of attribute mixing matrix vary on whether the matrix
    should include rows for attribute values that don't arise. Here we
    do not include such empty-rows. But you can force them to appear
    by inputting a `mapping` that includes those values.
    Examples
    --------
    >>> G = nx.path_graph(3)
    >>> gender = {0: "male", 1: "female", 2: "female"}
    >>> nx.set_node_attributes(G, gender, "gender")
    >>> mapping = {"male": 0, "female": 1}

62: (7)                    The edge attribute that holds the numerical value used
63: (7)                    as a weight.  If None, then each edge has weight 1.
64: (7)                    The degree is the sum of the edge weights adjacent to the node.
65: (4)                 nodes: list or iterable (optional)
66: (8)                     Use only edges that are adjacency to specified nodes.
67: (8)                     The default is all nodes.
68: (4)                 Returns
69: (4)                 -------
70: (4)                 (x, y): 2-tuple
71: (8)                     Generates 2-tuple of (degree, degree) values.
72: (4)                 Examples
73: (4)                 --------
74: (4)                 >>> G = nx.DiGraph()
75: (4)                 >>> G.add_edge(1, 2)
76: (4)                 >>> list(nx.node_degree_xy(G, x="out", y="in"))
77: (4)                 [(1, 1)]
78: (4)                 >>> list(nx.node_degree_xy(G, x="in", y="out"))
79: (4)                 [(0, 0)]
80: (4)                 Notes
81: (4)                 -----
82: (4)                 For undirected graphs each edge is produced twice, once for each edge
83: (4)                 representation (u, v) and (v, u), with the exception of self-loop edges
84: (4)                 which only appear once.
85: (4)                 """

```

```
r""" This module provides functions and operations for bipartite
graphs.  Bipartite graphs `B = (U, V, E)` have two node sets `U,V` and edges in
`E` that only connect nodes from opposite sets. It is common in the literature
to use an spatial analogy referring to the two node sets as top and bottom nodes.
The bipartite algorithms are not imported into the networkx namespace
at the top level so the easiest way to use them is with:
>>> from networkx.algorithms import bipartite
NetworkX does not have a custom bipartite graph class but the Graph()
or DiGraph() classes can be used to represent bipartite graphs. However,
you have to keep track of which set each node belongs to, and make
sure that there is no edge between nodes of the same set. The convention used
in NetworkX is to use a node attribute named `bipartite` with values 0 or 1 to
identify the sets each node belongs to. This convention is not enforced in
the source code of bipartite functions, it's only a recommendation.
For example:
>>> B = nx.Graph()
>>> # Add nodes with the node attribute "bipartite"
>>> B.add_nodes_from([1, 2, 3, 4], bipartite=0)
>>> B.add_nodes_from(["a", "b", "c"], bipartite=1)
>>> # Add edges only between nodes of opposite node sets
>>> B.add_edges_from([(1, "a"), (1, "b"), (2, "b"), (2, "c"), (3, "c"), (4, "a")])
Many algorithms of the bipartite module of NetworkX require, as an argument, a
container with all the nodes that belong to one set, in addition to the bipartite
graph `B`. The functions in the bipartite package do not check that the node set
is actually correct nor that the input graph is actually bipartite.
If `B` is connected, you can find the two node sets using a two-coloring
algorithm:
>>> nx.is_connected(B)
True
>>> bottom_nodes, top_nodes = bipartite.sets(B)
However, if the input graph is not connected, there are more than one possible
colorations. This is the reason why we require the user to pass a container
with all nodes of one bipartite node set as an argument to most bipartite
functions. In the face of ambiguity, we refuse the temptation to guess and
raise an :exc:`AmbiguousSolution <networkx.AmbiguousSolution>`
Exception if the input graph for
:func:`bipartite.sets <networkx.algorithms.bipartite.basic.sets>`
is disconnected.
Using the `bipartite` node attribute, you can easily get the two node sets:
>>> top_nodes = {n for n, d in B.nodes(data=True) if d["bipartite"] == 0}
>>> bottom_nodes = set(B) - top_nodes
So you can easily use the bipartite algorithms that require, as an argument, a
container with all nodes that belong to one node set:
>>> print(round(bipartite.density(B, bottom_nodes), 2))
0.5
>>> G = bipartite.projected_graph(B, top_nodes)
All bipartite graph generators in NetworkX build bipartite graphs with the
`bipartite` node attribute. Thus, you can use the same approach:
>>> RB = bipartite.random_graph(5, 7, 0.2)
>>> RB_top = {n for n, d in RB.nodes(data=True) if d["bipartite"] == 0}
>>> RB_bottom = set(RB) - RB_top
>>> list(RB_top)
[0, 1, 2, 3, 4]
>>> list(RB_bottom)
[5, 6, 7, 8, 9, 10, 11]
For other bipartite graph generators see
:mod:`Generators <networkx.algorithms.bipartite.generators>`.

    Raises an exception if the graph is not bipartite or if the input
    graph is disconnected and thus more than one valid solution exists.
    See :mod:`bipartite documentation <networkx.algorithms.bipartite>`
    for further details on how bipartite graphs are handled in NetworkX.
    Parameters
    ----------
    G : NetworkX graph
    top_nodes : container, optional
      Container with all nodes in one bipartite node set. If not supplied
      it will be computed. But if more than one solution exists an exception
      will be raised.
    Returns
    -------
    X : set
      Nodes from one side of the bipartite graph.
    Y : set
      Nodes from the other side.
    Raises
    ------
    AmbiguousSolution
      Raised if the input bipartite graph is disconnected and no container
      with all nodes in one bipartite set is provided. When determining
      the nodes in each bipartite set more than one valid solution is
      possible if the input graph is disconnected.
    NetworkXError
      Raised if the input graph is not bipartite.
    Examples
    --------
    >>> from networkx.algorithms import bipartite
    >>> G = nx.path_graph(4)
    >>> X, Y = bipartite.sets(G)
    >>> list(X)
    [0, 2]
    >>> list(Y)
    [1, 3]

(4)             :func:`~networkx.algorithms.bipartite.basic.is_bipartite`
(4)             Notes
(4)             -----
(4)             The nodes input parameter must contain all nodes in one bipartite node
set,
(4)             but the dictionary returned contains all nodes from both node sets.
(4)             See :mod:`bipartite documentation <networkx.algorithms.bipartite>`
(4)             for further details on how bipartite graphs are handled in NetworkX.
(4)             Closeness centrality is normalized by the minimum distance possible.
(4)             In the bipartite case the minimum distance for a node in one bipartite
(4)             node set is 1 from all nodes in the other node set and 2 from all
(4)             other nodes in its own set [1]_. Thus the closeness centrality
(4)             for node `v`  in the two bipartite sets `U` with
(4)             `n` nodes and `V` with `m` nodes is
(4)             .. math::
(8)                 c_{v} = \frac{m + 2(n - 1)}{d}, \mbox{for} v \in U,
(8)                 c_{v} = \frac{n + 2(m - 1)}{d}, \mbox{for} v \in V,
(4)             where `d` is the sum of the distances from `v` to all
(4)             other nodes.
(4)             Higher values of closeness  indicate higher centrality.
(4)             As in the unipartite case, setting normalized=True causes the
(4)             values to normalized further to n-1 / size(G)-1 where n is the
(4)             number of nodes in the connected part of graph containing the
```

30: (4)                 -----
31: (4)                 Definition:
32: (4)                 Let `G` be a simple, connected, undirected and bipartite graph with a
perfect
33: (4)                 matching M and bipartition (U,V). The residual graph of `G`, denoted by
$G_M$,
34: (4)                 is the graph obtained from G by directing the edges of M from V to U and
the
35: (4)                 edges that do not belong to M from U to V.
36: (4)                 Lemma [1]_ :
37: (4)                 Let M be a perfect matching of `G`. `G` is $k$-extendable if and only if
its residual
38: (4)                 graph $G_M$ is strongly connected and there are $k$ vertex-disjoint
directed
39: (4)                 paths between every vertex of U and every vertex of V.
40: (4)                 Assuming that input graph `G` is undirected, simple, connected, bipartite
and contains
41: (4)                 a perfect matching M, this function constructs the residual graph $G_M$ of
G and
```

```
42: (4)                 returns the minimum value among the maximum vertex-disjoint directed paths
between
43: (4)                 every vertex of U and every vertex of V in $G_M$. By combining the
definitions
44: (4)                 and the lemma, this value represents the extendability of the graph `G`.
45: (4)                 Time complexity O($n^3$ $m^2$)) where $n$ is the number of vertices
46: (4)                 and $m$ is the number of edges.

20: (4)                 used instead of 1.
```

```
(4)                 Parameters
(4)                 ----------
(4)                 G : graph
(7)                    A NetworkX graph
(4)                 row_order : list of nodes
(7)                    The rows of the matrix are ordered according to the list of nodes.
(4)                 column_order : list, optional
(7)                    The columns of the matrix are ordered according to the list of nodes.
(7)                    If column_order is None, then the ordering of columns is arbitrary.
(4)                 dtype : NumPy data-type, optional
(8)                     A valid NumPy dtype used to initialize the array. If None, then the
(8)                     NumPy default is used.
(4)                 weight : string or None, optional (default='weight')
(7)                    The edge data key used to provide each value in the matrix.
(7)                    If None, then each edge has weight 1.
(4)                 format : str in {'bsr', 'csr', 'csc', 'coo', 'lil', 'dia', 'dok'}
(8)                     The type of the matrix to be returned (default 'csr').  For
(8)                     some algorithms different implementations of sparse matrices
(8)                     can perform better.  See [2]_ for details.
(4)                 Returns
(4)                 -------
(4)                 M : SciPy sparse array
(8)                     Biadjacency matrix representation of the bipartite graph G.
(4)                 Notes
(4)                 -----
(4)                 No attempt is made to check that the input graph is bipartite.
(4)                 For directed bipartite graphs only successors are considered as neighbors.
(4)                 To obtain an adjacency matrix with ones (or weight values) for both
(4)                 predecessors and successors you have to generate two biadjacency matrices
(4)                 where the rows of one of them are the columns of the other, and then add
(4)                 one to the transpose of the other.

```
1: (0)              """Provides functions for computing maximum cardinality matchings and minimum
2: (0)              weight full matchings in a bipartite graph.
3: (0)              If you don't care about the particular implementation of the maximum matching
4: (0)              algorithm, simply use the :func:`maximum_matching`. If you do care, you can
5: (0)              import one of the named maximum matching algorithms directly.
6: (0)              For example, to find a maximum matching in the complete bipartite graph with
7: (0)              two vertices on the left and three vertices on the right:
8: (0)              >>> G = nx.complete_bipartite_graph(2, 3)
9: (0)              >>> left, right = nx.bipartite.sets(G)
10: (0)             >>> list(left)
11: (0)             [0, 1]
12: (0)             >>> list(right)
13: (0)             [2, 3, 4]
14: (0)             >>> nx.bipartite.maximum_matching(G)
15: (0)             {0: 2, 1: 3, 2: 0, 3: 1}
16: (0)             The dictionary returned by :func:`maximum_matching` includes a mapping for
```

```
vertices in both the left and right vertex sets.
Similarly, :func:`minimum_weight_full_matching` produces, for a complete
weighted bipartite graph, a matching whose cardinality is the cardinality of
the smaller of the two partitions, and for which the sum of the weights of the
edges included in the matching is minimal.

]
INFINITY = float("inf")
@nx._dispatchable
def hopcroft_karp_matching(G, top_nodes=None):
    """Returns the maximum cardinality matching of the bipartite graph `G`.
    A matching is a set of edges that do not share any nodes. A maximum
    cardinality matching is a matching with the most edges possible. It
    is not always unique. Finding a matching in a bipartite graph can be
    treated as a networkx flow problem.
    The functions ``hopcroft_karp_matching`` and ``maximum_matching``
    are aliases of the same function.
    Parameters
    ----------
    G : NetworkX graph
      Undirected bipartite graph
    top_nodes : container of nodes
      Container with all nodes in one bipartite node set. If not supplied
      it will be computed. But if more than one solution exists an exception
      will be raised.
    Returns
    -------
    matches : dictionary
      The matching is returned as a dictionary, `matches`, such that
      ``matches[v] == w`` if node `v` is matched to node `w`. Unmatched
      nodes do not occur as a key in `matches`.
    Raises
    ------
    AmbiguousSolution
      Raised if the input bipartite graph is disconnected and no container
      with all nodes in one bipartite set is provided. When determining
      the nodes in each bipartite set more than one valid solution is
      possible if the input graph is disconnected.
    Notes
    -----
    This function is implemented with the `Hopcroft--Karp matching algorithm
    <https://en.wikipedia.org/wiki/Hopcroft%E2%80%93Karp_algorithm>`_ for
    bipartite graphs.
    See :mod:`bipartite documentation <networkx.algorithms.bipartite>`
    for further details on how bipartite graphs are handled in NetworkX.

23: (6)                   The input graph should be bipartite.
24: (4)                 nodes : list or iterable
25: (6)                   Nodes to project onto (the "bottom" nodes).
26: (4)                 multigraph: bool (default=False)
```

```
   If True return a multigraph where the multiple edges represent multiple
   shared neighbors.  They edge key in the multigraph is assigned to the
   label of the neighbor.
Returns
-------
Graph : NetworkX graph or multigraph
   A graph that is the projection onto the given nodes.
Examples
--------
>>> from networkx.algorithms import bipartite
>>> B = nx.path_graph(4)
>>> G = bipartite.projected_graph(B, [1, 3])
>>> list(G)
[1, 3]
>>> list(G.edges())
[(1, 3)]
If nodes `a`, and `b` are connected through both nodes 1 and 2 then
building a multigraph results in two edges in the projection onto
[`a`, `b`]:
>>> B = nx.Graph()
>>> B.add_edges_from([("a", 1), ("b", 1), ("a", 2), ("b", 2)])
>>> G = bipartite.projected_graph(B, ["a", "b"], multigraph=True)
>>> print([sorted((u, v)) for u, v in G.edges()])
[['a', 'b'], ['a', 'b']]
Notes
-----
No attempt is made to verify that the input graph B is bipartite.
Returns a simple graph that is the projection of the bipartite graph B
onto the set of nodes given in list nodes.  If multigraph=True then
a multigraph is returned with an edge for every shared neighbor.
Directed graphs are allowed as input.  The output will also then
be a directed graph with edges if there is a directed path between
the nodes.
The graph and node properties are (shallow) copied to the projected graph.
See :mod:`bipartite documentation <networkx.algorithms.bipartite>`
for further details on how bipartite graphs are handled in NetworkX.

13: (6)                   Nodes to return value of spectral bipartivity contribution.
14: (4)                 weight : string or None  optional (default = 'weight')
15: (6)                   Edge data key to use for edge weights. If None, weights set to 1.
16: (4)                 Returns
17: (4)                 -------
18: (4)                 sb : float or dict
19: (7)                    A single number if the keyword nodes is not specified, or
20: (7)                    a dictionary keyed by node with the spectral bipartivity contribution
21: (7)                    of that node as the value.
22: (4)                 Examples
23: (4)                 --------
24: (4)                 >>> from networkx.algorithms import bipartite
25: (4)                 >>> G = nx.path_graph(4)
26: (4)                 >>> bipartite.spectral_bipartivity(G)
27: (4)                 1.0
28: (4)                 Notes
29: (4)                 -----
30: (4)                 This implementation uses Numpy (dense) matrices which are not efficient
31: (4)                 for storing large sparse graphs.
32: (4)                 See Also
33: (4)                 --------

@py_random_state(5)
@nx._dispatchable(edge_attrs="weight")
def betweenness_centrality(
    G, k=None, normalized=True, weight=None, endpoints=False, seed=None
):
    r"""Compute the shortest-path betweenness centrality for nodes.
    Betweenness centrality of a node $v$ is the sum of the
    fraction of all-pairs shortest paths that pass through $v$
    .. math::
       c_B(v) =\sum_{s,t \in V} \frac{\sigma(s, t|v)}{\sigma(s, t)}
    where $V$ is the set of nodes, $\sigma(s, t)$ is the number of
    shortest $(s, t)$-paths,  and $\sigma(s, t|v)$ is the number of
    those paths  passing through some  node $v$ other than $s, t$.
    If $s = t$, $\sigma(s, t) = 1$, and if $v \in {s, t}$,
    $\sigma(s, t|v) = 0$ [2]_.
    Parameters
    ----------
    G : graph
      A NetworkX graph.
    k : int, optional (default=None)
      If k is not None use k node samples to estimate betweenness.
      The value of k <= n where n is the number of nodes in the graph.
      Higher values give better approximation.
    normalized : bool, optional
      If True the betweenness values are normalized by `2/((n-1)(n-2))`
      for graphs, and `1/((n-1)(n-2))` for directed graphs where `n`
      is the number of nodes in G.
    weight : None or string, optional (default=None)
      If None, all edge weights are considered equal.
      Otherwise holds the name of the edge attribute used as weight.
      Weights are used to calculate weighted shortest paths, so they are
      interpreted as distances.
    endpoints : bool, optional
      If True include the endpoints in the shortest path counts.
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
        Note that this is only used if k is not None.
    Returns
    -------
    nodes : dictionary
       Dictionary of nodes with betweenness centrality as the value.
    See Also
    --------
    edge_betweenness_centrality
    load_centrality
    Notes
    -----
    The algorithm is from Ulrik Brandes [1]_.
    See [4]_ for the original first published version and [2]_ for details on
    algorithms for variations and related metrics.
    For approximate betweenness calculations set k=#samples to use
    k nodes ("pivots") to estimate the betweenness values. For an estimate
    of the number of pivots needed see [3]_.
    For weighted graphs the edge weights must be greater than zero.
    Zero edge weights can produce an infinite number of equal length
    paths between pairs of nodes.
    The total number of paths between source and target is counted
    differently for directed and undirected graphs. Directed paths
    are easy to count. Undirected paths are tricky: should a path
    from "u" to "v" count as 1 undirected path or as 2 directed paths?
    For betweenness_centrality we report the number of undirected
    paths when G is undirected.
    For betweenness_centrality_subset the reporting is different.
    If the source and target subsets are the same, then we want
```

```
 75: (4)                 to count undirected paths. But if the source and target subsets
 76: (4)                 differ -- for example, if sources is {0} and targets is {1},
 77: (4)                 then we are only counting the paths in one direction. They are
 78: (4)                 undirected paths but we are counting them in a directed way.
 79: (4)                 To count them as undirected paths, each should count as half a path.
 80: (4)                 This algorithm is not guaranteed to be correct if edge weights
 81: (4)                 are floating point numbers. As a workaround you can use integer
 82: (4)                 numbers by multiplying the relevant edge attributes by a convenient
 83: (4)                 constant factor (eg 100) and converting to integers.

```

```
(4)                 edge_betweenness_centrality
(4)                 load_centrality
(4)                 Notes
(4)                 -----
(4)                 The basic algorithm is from [1]_.
(4)                 For weighted graphs the edge weights must be greater than zero.
(4)                 Zero edge weights can produce an infinite number of equal length
(4)                 paths between pairs of nodes.
(4)                 The normalization might seem a little strange but it is
(4)                 designed to make betweenness_centrality(G) be the same as
(4)                 betweenness_centrality_subset(G,sources=G.nodes(),targets=G.nodes()).
(4)                 The total number of paths between source and target is counted
(4)                 differently for directed and undirected graphs. Directed paths
(4)                 are easy to count. Undirected paths are tricky: should a path
(4)                 from "u" to "v" count as 1 undirected path or as 2 directed paths?
(4)                 For betweenness_centrality we report the number of undirected
(4)                 paths when G is undirected.
(4)                 For betweenness_centrality_subset the reporting is different.
(4)                 If the source and target subsets are the same, then we want
(4)                 to count undirected paths. But if the source and target subsets
(4)                 differ -- for example, if sources is {0} and targets is {1},
(4)                 then we are only counting the paths in one direction. They are
(4)                 undirected paths but we are counting them in a directed way.
(4)                 To count them as undirected paths, each should count as half a path.

11: (4)                 r"""Compute closeness centrality for nodes.
12: (4)                 Closeness centrality [1]_ of a node `u` is the reciprocal of the
13: (4)                 average shortest path distance to `u` over all `n-1` reachable nodes.
14: (4)                 .. math::
15: (8)                     C(u) = \frac{n - 1}{\sum_{v=1}^{n-1} d(v, u)},
16: (4)                 where `d(v, u)` is the shortest-path distance between `v` and `u`,
17: (4)                 and `n-1` is the number of nodes reachable from `u`. Notice that the
18: (4)                 closeness distance function computes the incoming distance to `u`
19: (4)                 for directed graphs. To use outward distance, act on `G.reverse()`.
20: (4)                 Notice that higher values of closeness indicate higher centrality.
21: (4)                 Wasserman and Faust propose an improved formula for graphs with
22: (4)                 more than one connected component. The result is "a ratio of the
23: (4)                 fraction of actors in the group who are reachable, to the average
24: (4)                 distance" from the reachable actors [2]_. You might think this
```

```
(4)                 scale factor is inverted but it is not. As is, nodes from small
(4)                 components receive a smaller closeness value. Letting `N` denote
(4)                 the number of nodes in the graph,
(4)                 .. math::
(8)                     C_{WF}(u) = \frac{n-1}{N-1} \frac{n - 1}{\sum_{v=1}^{n-1} d(v, u)},
(4)                 Parameters
(4)                 ----------
(4)                 G : graph
(6)                   A NetworkX graph
(4)                 u : node, optional
(6)                   Return only the value for node u
(4)                 distance : edge attribute key, optional (default=None)
(6)                   Use the specified edge attribute as the edge distance in shortest
(6)                   path calculations.  If `None` (the default) all edges have a distance of
1.
(6)                   Absent edge attributes are assigned a distance of 1. Note that no check
(6)                   is performed to ensure that edges have the provided attribute.
(4)                 wf_improved : bool, optional (default=True)
(6)                   If True, scale by the fraction of nodes reachable. This gives the
(6)                   Wasserman and Faust improved formula. For single component graphs
(6)                   it is the same as the original formula.
(4)                 Returns
(4)                 -------
(4)                 nodes : dictionary
(6)                   Dictionary of nodes with closeness centrality as the value.
(4)                 Examples
(4)                 --------
(4)                 >>> G = nx.Graph([(0, 1), (0, 2), (0, 3), (1, 2), (1, 3)])
(4)                 >>> nx.closeness_centrality(G)
(4)                 {0: 1.0, 1: 1.0, 2: 0.75, 3: 0.75}
(4)                 See Also
(4)                 --------
(4)                 betweenness_centrality, load_centrality, eigenvector_centrality,
(4)                 degree_centrality, incremental_closeness_centrality
(4)                 Notes
(4)                 -----
(4)                 The closeness centrality is normalized to `(n-1)/(|G|-1)` where
(4)                 `n` is the number of nodes in the connected part of graph
(4)                 containing the node.  If the graph is not completely connected,
(4)                 this algorithm computes the closeness centrality for each
(4)                 connected part separately scaled by that parts size.
(4)                 If the 'distance' keyword is set to an edge attribute key then the
(4)                 shortest-path length will be computed using Dijkstra's algorithm with
(4)                 that edge attribute as the edge weight.
(4)                 The closeness centrality uses *inward* distance to a node, not outward.
(4)                 If you want to use outword distances apply the function to `G.reverse()`
(4)                 In NetworkX 2.2 and earlier a bug caused Dijkstra's algorithm to use the
(4)                 outward distance rather than the inward distance. If you use a 'distance'
(4)                 keyword and a DiGraph, your results will change between v2.2 and v2.3.

115: (4)                Compute closeness centrality for nodes using level-based work filtering
116: (4)                as described in Incremental Algorithms for Closeness Centrality by
Sariyuce et al.
117: (4)                Level-based work filtering detects unnecessary updates to the closeness
118: (4)                centrality and filters them out.
119: (4)                ---
120: (4)                From "Incremental Algorithms for Closeness Centrality":
121: (4)                Theorem 1: Let :math:`G = (V, E)` be a graph and u and v be two vertices
in V
122: (4)                such that there is no edge (u, v) in E. Let :math:`G' = (V, E \cup uv)`
123: (4)                Then :math:`cc[s] = cc'[s]` if and only if :math:`\left|dG(s, u) - dG(s,
v)\right| \leq 1`.
124: (4)                Where :math:`dG(u, v)` denotes the length of the shortest path between
125: (4)                two vertices u, v in a graph G, cc[s] is the closeness centrality for a
126: (4)                vertex s in V, and cc'[s] is the closeness centrality for a
127: (4)                vertex s in V, with the (u, v) edge added.
128: (4)                ---
129: (4)                We use Theorem 1 to filter out updates when adding or removing an edge.
130: (4)                When adding an edge (u, v), we compute the shortest path lengths from all
131: (4)                other nodes to u and to v before the node is added. When removing an edge,
132: (4)                we compute the shortest path lengths after the edge is removed. Then we
133: (4)                apply Theorem 1 to use previously computed closeness centrality for nodes
134: (4)                where :math:`\left|dG(s, u) - dG(s, v)\right| \leq 1`. This works only for
135: (4)                undirected, unweighted graphs; the distance argument is not supported.
136: (4)                Closeness centrality [1]_ of a node `u` is the reciprocal of the
137: (4)                sum of the shortest path distances from `u` to all `n-1` other nodes.
138: (4)                Since the sum of distances depends on the number of nodes in the
139: (4)                graph, closeness is normalized by the sum of minimum possible
140: (4)                distances `n-1`.
141: (4)                .. math::
142: (8)                    C(u) = \frac{n - 1}{\sum_{v=1}^{n-1} d(v, u)},
143: (4)                where `d(v, u)` is the shortest-path distance between `v` and `u`,
144: (4)                and `n` is the number of nodes in the graph.
145: (4)                Notice that higher values of closeness indicate higher centrality.
146: (4)                Parameters

    r"""Compute the approximate current-flow betweenness centrality for nodes.
    Approximates the current-flow betweenness centrality within absolute
    error of epsilon with high probability [1]_.
    Parameters
    ----------
    G : graph
      A NetworkX graph
    normalized : bool, optional (default=True)
      If True the betweenness values are normalized by 2/[(n-1)(n-2)] where
      n is the number of nodes in G.
    weight : string or None, optional (default=None)
      Key for edge data used as the edge weight.
      If None, then use 1 as each edge weight.
      The weight reflects the capacity or the strength of the
      edge.
    dtype : data type (float)
      Default data type for internal matrices.
      Set to np.float32 for lower memory consumption.
    solver : string (default='full')
       Type of linear solver to use for computing the flow matrix.
       Options are "full" (uses most memory), "lu" (recommended), and
       "cg" (uses least memory).
    epsilon: float
        Absolute error tolerance.
    kmax: int
       Maximum number of sample node pairs to use for approximation.
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
    Returns
    -------
    nodes : dictionary
       Dictionary of nodes with betweenness centrality as the value.
    See Also
    --------
    current_flow_betweenness_centrality
    Notes
    -----
    The running time is $O((1/\epsilon^2)m{\sqrt k} \log n)$

File 139 - dispersion.py:
```

```
(0)  from itertools import combinations
(0)  import networkx as nx
(0)  __all__ = ["dispersion"]
(0)  @nx._dispatchable
(0)  def dispersion(G, u=None, v=None, normalized=True, alpha=1.0, b=0.0, c=0.0):
(4)      r"""Calculate dispersion between `u` and `v` in `G`.
(4)      A link between two actors (`u` and `v`) has a high dispersion when their
(4)      mutual ties (`s` and `t`) are not well connected with each other.
(4)      Parameters
(4)      ----------
(4)      G : graph
(8)          A NetworkX graph.
(4)      u : node, optional
(8)          The source for the dispersion score (e.g. ego node of the network).
(4)      v : node, optional
(8)          The target of the dispersion score if specified.
(4)      normalized : bool
(8)          If True (default) normalize by the embeddedness of the nodes (u and
v).
(4)      alpha, b, c : float
(8)          Parameters for the normalization procedure. When `normalized` is True,
(8)          the dispersion value is normalized by::
(12)             result = ((dispersion + b) ** alpha) / (embeddedness + c)
(8)          as long as the denominator is nonzero.
(4)      Returns
(4)      -------
(4)      nodes : dictionary
(8)          If u (v) is specified, returns a dictionary of nodes with dispersion
(8)          score for all "target" ("source") nodes. If neither u nor v is
(8)          specified, returns a dictionary of dictionaries for all nodes 'u' in
the
(8)          graph with a dispersion score for each node 'v'.
(4)      Notes
(4)      -----
(4)      This implementation follows Lars Backstrom and Jon Kleinberg [1]_. Typical
(4)      usage would be to run dispersion on the ego network $G_u$ if $u$ were
(4)      specified.  Running :func:`dispersion` with neither $u$ nor $v$ specified
(4)      can take some time to complete.

11: (4)                 the centrality of its predecessors. The centrality for node $i$ is the
12: (4)                 $i$-th element of a left eigenvector associated with the eigenvalue
$\lambda$
13: (4)                 of maximum modulus that is positive. Such an eigenvector $x$ is
14: (4)                 defined up to a multiplicative constant by the equation
15: (4)                 .. math::
16: (9)                      \lambda x^T = x^T A,
17: (4)                 where $A$ is the adjacency matrix of the graph G. By definition of
18: (4)                 row-column product, the equation above is equivalent to
19: (4)                 .. math::
20: (8)                     \lambda x_i = \sum_{j\to i}x_j.
21: (4)                 That is, adding the eigenvector centralities of the predecessors of
22: (4)                 $i$ one obtains the eigenvector centrality of $i$ multiplied by
23: (4)                 $\lambda$. In the case of undirected graphs, $x$ also solves the familiar
24: (4)                 right-eigenvector equation $Ax = \lambda x$.
25: (4)                 By virtue of the Perron–Frobenius theorem [1]_, if G is strongly
26: (4)                 connected there is a unique eigenvector $x$, and all its entries
27: (4)                 are strictly positive.
28: (4)                 If G is not strongly connected there might be several left
29: (4)                 eigenvectors associated with $\lambda$, and some of their elements
30: (4)                 might be zero.
31: (4)                 Parameters
32: (4)                 ----------
33: (4)                 G : graph
34: (6)                   A networkx graph.
35: (4)                 max_iter : integer, optional (default=100)
36: (6)                   Maximum number of power iterations.
37: (4)                 tol : float, optional (default=1.0e-6)
38: (6)                   Error tolerance (in Euclidean norm) used to check convergence in
39: (6)                   power iteration.
40: (4)                 nstart : dictionary, optional (default=None)
41: (6)                   Starting value of power iteration for each node. Must have a nonzero
42: (6)                   projection on the desired eigenvector for the power method to converge.
43: (6)                   If None, this implementation uses an all-ones vector, which is a safe
44: (6)                   choice.
45: (4)                 weight : None or string, optional (default=None)
46: (6)                   If None, all edge weights are considered equal. Otherwise holds the
47: (6)                   name of the edge attribute used as weight. In this measure the
48: (6)                   weight is interpreted as the connection strength.
49: (4)                 Returns

(4)                 Notes
(4)                 -----
(4)                 Eigenvector centrality was introduced by Landau [2]_ for chess
(4)                 tournaments. It was later rediscovered by Wei [3]_ and then
(4)                 popularized by Kendall [4]_ in the context of sport ranking. Berge
(4)                 introduced a general definition for graphs based on social connections
(4)                 [5]_. Bonacich [6]_ reintroduced again eigenvector centrality and made
(4)                 it popular in link analysis.
(4)                 This function computes the left dominant eigenvector, which corresponds
(4)                 to adding the centrality of predecessors: this is the usual approach.
(4)                 To add the centrality of successors first reverse the graph with
(4)                 ``G.reverse()``.
(4)                 The implementation uses power iteration [7]_ to compute a dominant
(4)                 eigenvector starting from the provided vector `nstart`. Convergence is
(4)                 guaranteed as long as `nstart` has a nonzero projection on a dominant
(4)                 eigenvector, which certainly happens using the default value.
(4)                 The method stops when the change in the computed vector between two
(4)                 iterations is smaller than an error tolerance of ``G.number_of_nodes()
(4)                 * tol`` or after ``max_iter`` iterations, but in the second case it
(4)                 raises an exception.
(4)                 This implementation uses $(A + I)$ rather than the adjacency matrix
(4)                 $A$ because the change preserves eigenvectors, but it shifts the
(4)                 spectrum, thus guaranteeing convergence even for networks with
(4)                 negative eigenvalues of maximum modulus.

(4)             nodes : dictionary
```

```
   Dictionary of nodes with eigenvector centrality as the value. The
   associated vector has unit Euclidean norm and the values are
   nonegative.
Examples
--------
>>> G = nx.path_graph(4)
>>> centrality = nx.eigenvector_centrality_numpy(G)
>>> print([f"{node} {centrality[node]:0.2f}" for node in centrality])
['0 0.37', '1 0.60', '2 0.60', '3 0.37']
Raises
------
NetworkXPointlessConcept
    If the graph G is the null graph.
ArpackNoConvergence
    When the requested convergence is not obtained. The currently
    converged eigenvalues and eigenvectors can be found as
    eigenvalues and eigenvectors attributes of the exception object.

which group betweenness
36: (6)                   centrality is to be calculated.
37: (4)                 normalized : bool, optional (default=True)
38: (6)                   If True, group betweenness is normalized by `1/((|V|-|C|)(|V|-|C|-1))`
39: (6)                   where `|V|` is the number of nodes in G and `|C|` is the number of nodes
in C.
40: (4)                 weight : None or string, optional (default=None)
41: (6)                   If None, all edge weights are considered equal.
42: (6)                   Otherwise holds the name of the edge attribute used as weight.
43: (6)                   The weight of an edge is treated as the length or distance between the
two sides.
44: (4)                 endpoints : bool, optional (default=False)
45: (6)                   If True include the endpoints in the shortest path counts.
46: (4)                 Raises
47: (4)                 ------
48: (4)                 NodeNotFound
49: (7)                    If node(s) in C are not present in G.
50: (4)                 Returns
51: (4)                 -------
52: (4)                 betweenness : list of floats or float
```

```
53: (7)                    If C is a single group then return a float. If C is a list with
54: (7)                    several groups then return a list of group betweenness centralities.
55: (4)                 See Also

57: (4)                 betweenness_centrality
58: (4)                 Notes
59: (4)                 -----
60: (4)                 Group betweenness centrality is described in [1]_ and its importance
discussed in [3]_.
61: (4)                 The initial implementation of the algorithm is mentioned in [2]_. This
function uses
62: (4)                 an improved algorithm presented in [4]_.
63: (4)                 The number of nodes in the group must be a maximum of n - 2 where `n`
64: (4)                 is the total number of nodes in the graph.
65: (4)                 For weighted graphs the edge weights must be greater than zero.
66: (4)                 Zero edge weights can produce an infinite number of equal length
67: (4)                 paths between pairs of nodes.
68: (4)                 The total number of paths between source and target is counted
69: (4)                 differently for directed and undirected graphs. Directed paths
70: (4)                 between "u" and "v" are counted as two possible paths (one each
71: (4)                 direction) while undirected paths between "u" and "v" are counted
72: (4)                 as one path. Said another way, the sum in the expression above is
73: (4)                 over all ``s != t`` for directed graphs and for ``s < t`` for undirected
graphs.

```

```
(4)                 -----
(4)                 Group betweenness centrality is described in [1]_ and its importance discussed in [3]_.
(4)                 The algorithm is described in [2]_ and is based on techniques mentioned in [4]_.
(4)                 The number of nodes in the group must be a maximum of ``n - 2`` where ``n``
(4)                 is the total number of nodes in the graph.
(4)                 For weighted graphs the edge weights must be greater than zero.
(4)                 Zero edge weights can produce an infinite number of equal length
(4)                 paths between pairs of nodes.
(4)                 The total number of paths between source and target is counted
(4)                 differently for directed and undirected graphs. Directed paths
(4)                 between "u" and "v" are counted as two possible paths (one each
(4)                 direction) while undirected paths between "u" and "v" are counted
(4)                 as one path. Said another way, the sum in the expression above is
(4)                 over all ``s != t`` for directed graphs and for ``s < t`` for undirected graphs.

(0)             def group_closeness_centrality(G, S, weight=None):
(4)                 r"""Compute the group closeness centrality for a group of nodes.
(4)                 Group closeness centrality of a group of nodes $S$ is a measure
(4)                 of how close the group is to the other nodes in the graph.
(4)                 .. math::
(7)                    c_{close}(S) = \frac{|V-S|}{\sum_{v \in V-S} d_{S, v}}
(7)                    d_{S, v} = min_{u \in S} (d_{u, v})
(4)                 where $V$ is the set of nodes, $d_{S, v}$ is the distance of
(4)                 the group $S$ from $v$ defined as above. ($V-S$ is the set of nodes
(4)                 in $V$ that are not in $S$).
(4)                 Parameters
(4)                 ----------
(4)                 G : graph
(7)                    A NetworkX graph.
(4)                 S : list or set
(7)                    S is a group of nodes which belong to G, for which group closeness
(7)                    centrality is to be calculated.
(4)                 weight : None or string, optional (default=None)
(7)                    If None, all edge weights are considered equal.
(7)                    Otherwise holds the name of the edge attribute used as weight.
(7)                    The weight of an edge is treated as the length or distance between the
two sides.
(4)                 Raises
(4)                 ------
(4)                 NodeNotFound
(7)                    If node(s) in S are not present in G.
(4)                 Returns
(4)                 -------
(4)                 closeness : float
(7)                    Group closeness centrality of the group S.
(4)                 See Also
(4)                 --------
(4)                 closeness_centrality
(4)                 Notes
(4)                 -----
(4)                 The measure was introduced in [1]_.
(4)                 The formula implemented here is described in [2]_.
(4)                 Higher values of closeness indicate greater centrality.
(4)                 It is assumed that 1 / 0 is 0 (required in the case of directed graphs,
(4)                 or when a shortest path length is 0).
(4)                 The number of nodes in the group must be a maximum of n - 1 where `n`
(4)                 is the total number of nodes in the graph.
(4)                 For directed graphs, the incoming distance is utilized here. To use the
(4)                 outward distance, act on `G.reverse()`.
(4)                 For weighted graphs the edge weights must be greater than zero.
(4)                 Zero edge weights can produce an infinite number of equal length
(4)                 paths between pairs of nodes.

91: (4)               Notes
92: (4)               -----
93: (4)               Katz centrality was introduced by [2]_.
94: (4)               This algorithm it uses the power method to find the eigenvector
95: (4)               corresponding to the largest eigenvalue of the adjacency matrix of ``G``.
96: (4)               The parameter ``alpha`` should be strictly less than the inverse of
largest
97: (4)               eigenvalue of the adjacency matrix for the algorithm to converge.
98: (4)               You can use ``max(nx.adjacency_spectrum(G))`` to get $\lambda_{\max}$ the
largest
99: (4)               eigenvalue of the adjacency matrix.
100: (4)              The iteration will stop after ``max_iter`` iterations or an error
tolerance of
101: (4)              ``number_of_nodes(G) * tol`` has been reached.
102: (4)              For strongly connected graphs, as $\alpha \to 1/\lambda_{\max}$, and
$\beta > 0$,
103: (4)              Katz centrality approaches the results for eigenvector centrality.
104: (4)              For directed graphs this finds "left" eigenvectors which corresponds
105: (4)              to the in-edges in the graph. For out-edges Katz centrality,
106: (4)              first reverse the graph with ``G.reverse()``.

(4)                 Notes
(4)                 -----
(4)                 Katz centrality was introduced by [2]_.
(4)                 This algorithm uses a direct linear solver to solve the above equation.
(4)                 The parameter ``alpha`` should be strictly less than the inverse of
largest
(4)                 eigenvalue of the adjacency matrix for there to be a solution.
(4)                 You can use ``max(nx.adjacency_spectrum(G))`` to get $\lambda_{\max}$ the
largest
(4)                 eigenvalue of the adjacency matrix.
(4)                 For strongly connected graphs, as $\alpha \to 1/\lambda_{\max}$, and
$\beta > 0$,
(4)                 Katz centrality approaches the results for eigenvector centrality.
(4)                 For directed graphs this finds "left" eigenvectors which corresponds
(4)                 to the in-edges in the graph. For out-edges Katz centrality,
(4)                 first reverse the graph with ``G.reverse()``.

8: (4)                  G, normalized=True, nodelist=None, weight="weight", walk_type=None,
alpha=0.95
9: (0)              ):
10: (4)                 r"""Compute the Laplacian centrality for nodes in the graph `G`.
11: (4)                 The Laplacian Centrality of a node ``i`` is measured by the drop in the
12: (4)                 Laplacian Energy after deleting node ``i`` from the graph. The Laplacian
Energy
13: (4)                 is the sum of the squared eigenvalues of a graph's Laplacian matrix.
14: (4)                 .. math::
15: (8)                     C_L(u_i,G) = \frac{(\Delta E)_i}{E_L (G)} = \frac{E_L (G)-E_L (G_i)}
{E_L (G)}
16: (8)                     E_L (G) = \sum_{i=0}^n \lambda_i^2
```

```
Where $E_L (G)$ is the Laplacian energy of graph `G`,
E_L (G_i) is the Laplacian energy of graph `G` after deleting node ``i``
and $\lambda_i$ are the eigenvalues of `G`'s Laplacian matrix.
This formula shows the normalized value. Without normalization,
the numerator on the right side is returned.
Parameters
----------
G : graph
    A networkx graph
normalized : bool (default = True)
    If True the centrality score is scaled so the sum over all nodes is 1.
    If False the centrality score for each node is the drop in Laplacian
    energy when that node is removed.
nodelist : list, optional (default = None)
    The rows and columns are ordered according to the nodes in nodelist.
    If nodelist is None, then the ordering is produced by G.nodes().
weight: string or None, optional (default=`weight`)
    Optional parameter `weight` to compute the Laplacian matrix.
    The edge data key used to compute each value in the matrix.
    If None, then each edge has weight 1.
walk_type : string or None, optional (default=None)
    Optional parameter `walk_type` used when calling
    :func:`directed_laplacian_matrix <networkx.directed_laplacian_matrix>`.
    One of ``"random"``, ``"lazy"``, or ``"pagerank"``. If ``walk_type=None``
    (the default), then a value is selected according to the properties of `G`:
    - ``walk_type="random"`` if `G` is strongly connected and aperiodic
    - ``walk_type="lazy"`` if `G` is strongly connected but not aperiodic
    - ``walk_type="pagerank"`` for all other cases.
alpha : real (default = 0.95)
    Optional parameter `alpha` used when calling
    :func:`directed_laplacian_matrix <networkx.directed_laplacian_matrix>`.
    (1 - alpha) is the teleportation probability used with pagerank.
Returns
-------
nodes : dictionary
   Dictionary of nodes with Laplacian centrality as the value.
Examples
--------
>>> G = nx.Graph()
>>> edges = [(0, 1, 4), (0, 2, 2), (2, 1, 1), (1, 3, 2), (1, 4, 2), (4, 5, 1)]
>>> G.add_weighted_edges_from(edges)
>>> sorted((v, f"{c:0.2f}") for v, c in laplacian_centrality(G).items())
[(0, '0.70'), (1, '0.90'), (2, '0.28'), (3, '0.22'), (4, '0.26'), (5, '0.04')]
Notes
-----
The algorithm is implemented based on [1]_ with an extension to directed graphs
using the ``directed_laplacian_matrix`` function.
Raises
------
NetworkXPointlessConcept
    If the graph `G` is the null graph.
ZeroDivisionError
    If the graph `G` has no edges (is empty) and normalization is requested.

15: (4)                 This measure quantifies relative impact of nodes based on their
16: (4)                 topological connectivity, as well as their percolation states.
17: (4)                 Percolation states of nodes are used to depict network percolation
```

```
scenarios (such as during infection transmission in a social network
of individuals, spreading of computer viruses on computer networks, or
transmission of disease over a network of towns) over time. In this
measure usually the percolation state is expressed as a decimal
between 0.0 and 1.0.
When all nodes are in the same percolated state this measure is
equivalent to betweenness centrality.
Parameters
----------
G : graph
  A NetworkX graph.
attribute : None or string, optional (default='percolation')
  Name of the node attribute to use for percolation state, used
  if `states` is None. If a node does not set the attribute the
  state of that node will be set to the default value of 1.
  If all nodes do not have the attribute all nodes will be set to
  1 and the centrality measure will be equivalent to betweenness
centrality.
states : None or dict, optional (default=None)
  Specify percolation states for the nodes, nodes as keys states
  as values.
weight : None or string, optional (default=None)
  If None, all edge weights are considered equal.
  Otherwise holds the name of the edge attribute used as weight.
  The weight of an edge is treated as the length or distance between the
two sides.
Returns
-------
nodes : dictionary
   Dictionary of nodes with percolation centrality as the value.
See Also
--------
betweenness_centrality
Notes
-----
The algorithm is from Mahendra Piraveenan, Mikhail Prokopenko, and
Liaquat Hossain [1]_
Pair dependencies are calculated and accumulated using [2]_
For weighted graphs the edge weights must be greater than zero.
Zero edge weights can produce an infinite number of equal length
paths between pairs of nodes.

    """Returns the local reaching centrality of a node in a directed
    graph.
    The *local reaching centrality* of a node in a directed graph is the
    proportion of other nodes reachable from that node [1]_.
    Parameters
    ----------
    G : DiGraph
        A NetworkX DiGraph.
    v : node
        A node in the directed graph `G`.
    paths : dictionary (default=None)
        If this is not `None` it must be a dictionary representation
        of single-source shortest paths, as computed by, for example,
        :func:`networkx.shortest_path` with source node `v`. Use this
        keyword argument if you intend to invoke this function many
        times but don't want the paths to be recomputed each time.
    weight : None or string, optional (default=None)
        Attribute to use for edge weights.  If `None`, each edge weight
        is assumed to be one. A higher weight implies a stronger
        connection between nodes and a *shorter* path length.
    normalized : bool, optional (default=True)
        Whether to normalize the edge weights by the total sum of edge
        weights.
    Returns
    -------
    h : float
        The local reaching centrality of the node ``v`` in the graph
        ``G``.
    Examples
    --------
```

```
120: (4)                >>> G = nx.DiGraph()
121: (4)                >>> G.add_edges_from([(1, 2), (1, 3)])

(4)                 Raises
(4)                 ------
(4)                 NetworkXException
(8)                     If the graph G is empty, non connected or has negative weights.
(4)                 See Also
(4)                 --------
(4)                 betweenness_centrality
(4)                 Notes
(4)                 -----
(4)                 Lower values of second order centrality indicate higher centrality.
(4)                 The algorithm is from Kermarrec, Le Merrer, Sericola and Trédan [1]_.
(4)                 This code implements the analytical version of the algorithm, i.e.,
(4)                 there is no simulation of a random walk process involved. The random walk
(4)                 is here unbiased (corresponding to eq 6 of the paper [1]_), thus the
(4)                 centrality values are the standard deviations for random walk return times
(4)                 on the transformed input graph G (equal in-degree at each nodes by adding
(4)                 self-loops).
(4)                 Complexity of this implementation, made to run locally on a single
machine,
(4)                 is O(n^3), with n the size of G, which makes it viable only for small
(4)                 graphs.
(4)                 References
(4)                 ----------
