File 363 - beamsearch.py:

```
1: (0)              """Basic algorithms for breadth-first searching the nodes of a graph."""
2: (0)              import networkx as nx
3: (0)              __all__ = ["bfs_beam_edges"]
4: (0)              @nx._dispatchable
5: (0)              def bfs_beam_edges(G, source, value, width=None):
6: (4)                  """Iterates over edges in a beam search.
7: (4)                  The beam search is a generalized breadth-first search in which only
8: (4)                  the "best" *w* neighbors of the current node are enqueued, where *w*
9: (4)                  is the beam width and "best" is an application-specific
10: (4)                 heuristic. In general, a beam search with a small beam width might
11: (4)                 not visit each node in the graph.
12: (4)                 .. note::
13: (7)                    With the default value of ``width=None`` or `width` greater than the
14: (7)                    maximum degree of the graph, this function equates to a slower
15: (7)                    version of
`~networkx.algorithms.traversal.breadth_first_search.bfs_edges`.
16: (7)                    All nodes will be visited, though the order of the reported edges may
17: (7)                    vary. In such cases, `value` has no effect - consider using `bfs_edges`
18: (7)                    directly instead.
19: (4)                 Parameters
20: (4)                 ----------
21: (4)                 G : NetworkX graph
22: (4)                 source : node
23: (8)                     Starting node for the breadth-first search; this function
24: (8)                     iterates over only those edges in the component reachable from
25: (8)                     this node.
26: (4)                 value : function
27: (8)                     A function that takes a node of the graph as input and returns a
28: (8)                     real number indicating how "good" it is. A higher value means it
29: (8)                     is more likely to be visited sooner during the search. When
30: (8)                     visiting a new node, only the `width` neighbors with the highest
31: (8)                     `value` are enqueued (in decreasing order of `value`).
32: (4)                 width : int (default = None)
33: (8)                     The beam width for the search. This is the number of neighbors
34: (8)                     (ordered by `value`) to enqueue when visiting each new node.
35: (4)                 Yields
36: (4)                 ------
37: (4)                 edge
38: (8)                     Edges in the beam search starting from `source`, given as a pair
39: (8)                     of nodes.
40: (4)                 Examples
41: (4)                 --------
42: (4)                 To give nodes with, for example, a higher centrality precedence
43: (4)                 during the search, set the `value` function to return the centrality
44: (4)                 value of the node:
45: (4)                 >>> G = nx.karate_club_graph()
46: (4)                 >>> centrality = nx.eigenvector_centrality(G)
47: (4)                 >>> list(nx.bfs_beam_edges(G, source=0, value=centrality.get, width=3))
48: (4)                 [(0, 2), (0, 1), (0, 8), (2, 32), (1, 13), (8, 33)]
49: (4)                 """
50: (4)                 if width is None:

17: (4)                 The breadth-first search begins at `source` and enqueues the
18: (4)                 neighbors of newly visited nodes specified by the `neighbors`
19: (4)                 function.
20: (4)                 Parameters
21: (4)                 ----------
22: (4)                 G : NetworkX graph
23: (4)                 source : node
24: (8)                     Starting node for the breadth-first search; this function
25: (8)                     iterates over only those edges in the component reachable from
26: (8)                     this node.
27: (4)                 neighbors : function
28: (8)                     A function that takes a newly visited node of the graph as input
29: (8)                     and returns an *iterator* (not just a list) of nodes that are
30: (8)                     neighbors of that node with custom ordering. If not specified, this is
31: (8)                     just the ``G.neighbors`` method, but in general it can be any function
32: (8)                     that returns an iterator over some or all of the neighbors of a
33: (8)                     given node, in any order.
34: (4)                 depth_limit : int, optional(default=len(G))
35: (8)                     Specify the maximum search depth.
36: (4)                 sort_neighbors : Callable (default=None)
37: (8)                     .. deprecated:: 3.2
38: (11)                       The sort_neighbors parameter is deprecated and will be removed in
39: (11)                       version 3.4. A custom (e.g. sorted) ordering of neighbors can be
40: (11)                       specified with the `neighbors` parameter.
41: (8)                     A function that takes an iterator over nodes as the input, and
42: (8)                     returns an iterable of the same nodes with a custom ordering.
43: (8)                     For example, `sorted` will sort the nodes in increasing order.
44: (4)                 Yields
45: (4)                 ------
46: (4)                 edge
47: (8)                     Edges in the breadth-first search starting from `source`.
48: (4)                 Examples
49: (4)                 --------
50: (4)                 >>> G = nx.path_graph(7)
51: (4)                 >>> list(nx.generic_bfs_edges(G, source=0))
52: (4)                 [(0, 1), (1, 2), (2, 3), (3, 4), (4, 5), (5, 6)]
53: (4)                 >>> list(nx.generic_bfs_edges(G, source=2))
54: (4)                 [(2, 1), (2, 3), (1, 0), (3, 4), (4, 5), (5, 6)]
55: (4)                 >>> list(nx.generic_bfs_edges(G, source=2, depth_limit=2))
56: (4)                 [(2, 1), (2, 3), (1, 0), (3, 4)]
57: (4)                 The `neighbors` param can be used to specify the visitation order of each
58: (4)                 node's neighbors generically. In the following example, we modify the
default
59: (4)                 neighbor to return *odd* nodes first:
60: (4)                 >>> def odd_first(n):
61: (4)                 ...     return sorted(G.neighbors(n), key=lambda x: x % 2, reverse=True)
62: (4)                 >>> G = nx.star_graph(5)
63: (4)                 >>> list(nx.generic_bfs_edges(G, source=0))  # Default neighbor ordering
64: (4)                 [(0, 1), (0, 2), (0, 3), (0, 4), (0, 5)]
65: (4)                 >>> list(nx.generic_bfs_edges(G, source=0, neighbors=odd_first))
66: (4)                 [(0, 1), (0, 3), (0, 5), (0, 2), (0, 4)]
67: (4)                 Notes
68: (4)                 -----
```

(8)                 >>> nodes
(8)                 [2, 1, 0]
(4)             Notes
(4)             -----
(4)             The naming of this function is very similar to
(4)             :func:`~networkx.algorithms.traversal.edgebfs.edge_bfs`. The difference
(4)             is that ``edge_bfs`` yields edges even if they extend back to an already
(4)             explored node while this generator yields the edges of the tree that
results
(4)             from a breadth-first-search (BFS) so no edges are reported if they extend
(4)             to already explored nodes. That means ``edge_bfs`` reports all edges while
(4)             ``bfs_edges`` only reports those traversed by a node-based BFS. Yet
another
(4)             description is that ``bfs_edges`` reports the edges traversed during BFS
(4)             while ``edge_bfs`` reports all edges in the order they are explored.
(4)             Based on the breadth-first search implementation in PADS [1]_
(4)             by D. Eppstein, July 2004; with modifications to allow depth limits
(4)             as described in [2]_.

(4)                 We generate triple of the form (*u*, *v*, *d*), where (*u*, *v*) is the
(4)                 edge being explored in the breadth-first search and *d* is one of the
```

```
    strings 'tree', 'forward', 'level', or 'reverse'.  A 'tree' edge is one in
    which *v* is first discovered and placed into the layer below *u*.  A
    'forward' edge is one in which *u* is on the layer above *v* and *v* has
    already been discovered.  A 'level' edge is one in which both *u* and *v*
    occur on the same layer.  A 'reverse' edge is one in which *u* is on a layer

    below *v*.
    We emit each edge exactly once.  In an undirected graph, 'reverse' edges do

    not occur, because each is discovered either as a 'tree' or 'forward' edge.
    Parameters
    ----------
    G : NetworkX graph
        A graph over which to find the layers using breadth-first search.
    sources : node in `G` or list of nodes in `G`
        Starting nodes for single source or multiple sources breadth-first search

    Yields
    ------
    edges: generator
       A generator of triples (*u*, *v*, *d*) where (*u*, *v*) is the edge being

       explored and *d* is described above.
    Examples
    --------
    >>> G = nx.cycle_graph(4, create_using=nx.DiGraph)
    >>> list(nx.bfs_labeled_edges(G, 0))
    [(0, 1, 'tree'), (1, 2, 'tree'), (2, 3, 'tree'), (3, 0, 'reverse')]

(4)                sort_neighbors : function (default=None)
(8)                    A function that takes an iterator over nodes as the input, and
(8)                    returns an iterable of the same nodes with a custom ordering.
(8)                    For example, `sorted` will sort the nodes in increasing order.
(4)                Returns
(4)                -------
(4)                edges: generator
(7)                   A generator of triples of the form (*u*, *v*, *d*), where (*u*,
(7)                   *v*) is the edge being explored in the depth-first search and *d*
(7)                   is one of the strings 'forward', 'nontree', 'reverse', or 'reverse-
depth_limit'.
(7)                   A 'forward' edge is one in which *u* has been visited but *v* has
(7)                   not. A 'nontree' edge is one in which both *u* and *v* have been
(7)                   visited but the edge is not in the DFS tree. A 'reverse' edge is
(7)                   one in which both *u* and *v* have been visited and the edge is in
(7)                   the DFS tree. When the `depth_limit` is reached via a 'forward' edge,
(7)                   a 'reverse' edge is immediately generated rather than the subtree
(7)                   being explored. To indicate this flavor of 'reverse' edge, the string
(7)                   yielded is 'reverse-depth_limit'.

`source`.
15: (4)                 Yield the edges of G in a breadth-first-search order continuing until
16: (4)                 all edges are generated.
17: (4)                 Parameters
18: (4)                 ----------
19: (4)                 G : graph
20: (8)                     A directed/undirected graph/multigraph.
21: (4)                 source : node, list of nodes
22: (8)                     The node from which the traversal begins. If None, then a source
23: (8)                     is chosen arbitrarily and repeatedly until all edges from each node in
24: (8)                     the graph are searched.
25: (4)                 orientation : None | 'original' | 'reverse' | 'ignore' (default: None)
26: (8)                     For directed graphs and directed multigraphs, edge traversals need not
27: (8)                     respect the original orientation of the edges.
28: (8)                     When set to 'reverse' every edge is traversed in the reverse
direction.
29: (8)                     When set to 'ignore', every edge is treated as undirected.
30: (8)                     When set to 'original', every edge is treated as directed.
31: (8)                     In all three cases, the yielded edge tuples add a last entry to
32: (8)                     indicate the direction in which that edge was traversed.
33: (8)                     If orientation is None, the yielded edge has no direction indicated.
34: (8)                     The direction is respected, but not reported.
35: (4)                 Yields
36: (4)                 ------
37: (4)                 edge : directed edge
38: (8)                     A directed edge indicating the path taken by the breadth-first-search.
39: (8)                     For graphs, `edge` is of the form `(u, v)` where `u` and `v`
40: (8)                     are the tail and head of the edge as determined by the traversal.
41: (8)                     For multigraphs, `edge` is of the form `(u, v, key)`, where `key` is
42: (8)                     the key of the edge. When the graph is directed, then `u` and `v`
43: (8)                     are always in the order of the actual directed edge.
44: (8)                     If orientation is not None then the edge tuple is extended to include
45: (8)                     the direction of traversal ('forward' or 'reverse') on that edge.
46: (4)                 Examples
47: (4)                 --------
48: (4)                 >>> nodes = [0, 1, 2, 3]

```

```
(4)     -----
(4)     The goal of this function is to visit edges. It differs from the more
(4)     familiar breadth-first-search of nodes, as provided by
(4)     :func:`networkx.algorithms.traversal.breadth_first_search.bfs_edges`, in
(4)     that it does not stop once every node has been visited. In a directed
graph
(4)     with edges [(0, 1), (1, 2), (2, 1)], the edge (2, 1) would not be visited
(4)     if not for the functionality provided by this function.
(4)     The naming of this function is very similar to bfs_edges. The difference
(4)     is that 'edge_bfs' yields edges even if they extend back to an already
(4)     explored node while 'bfs_edges' yields the edges of the tree that results
(4)     from a breadth-first-search (BFS) so no edges are reported if they extend
(4)     to already explored nodes. That means 'edge_bfs' reports all edges while
(4)     'bfs_edges' only report those traversed by a node-based BFS. Yet another
(4)     description is that 'bfs_edges' reports the edges traversed during BFS
(4)     while 'edge_bfs' reports all edges in the order they are explored.

14: (4)                 Yield the edges of G in a depth-first-search order continuing until
15: (4)                 all edges are generated.
16: (4)                 Parameters
17: (4)                 ----------
18: (4)                 G : graph
19: (8)                     A directed/undirected graph/multigraph.
20: (4)                 source : node, list of nodes
21: (8)                     The node from which the traversal begins. If None, then a source
22: (8)                     is chosen arbitrarily and repeatedly until all edges from each node in
23: (8)                     the graph are searched.
24: (4)                 orientation : None | 'original' | 'reverse' | 'ignore' (default: None)
25: (8)                     For directed graphs and directed multigraphs, edge traversals need not
26: (8)                     respect the original orientation of the edges.
27: (8)                     When set to 'reverse' every edge is traversed in the reverse
direction.
28: (8)                     When set to 'ignore', every edge is treated as undirected.
29: (8)                     When set to 'original', every edge is treated as directed.
30: (8)                     In all three cases, the yielded edge tuples add a last entry to
31: (8)                     indicate the direction in which that edge was traversed.
32: (8)                     If orientation is None, the yielded edge has no direction indicated.
33: (8)                     The direction is respected, but not reported.
34: (4)                 Yields
35: (4)                 ------
36: (4)                 edge : directed edge
37: (8)                     A directed edge indicating the path taken by the depth-first
traversal.
38: (8)                     For graphs, `edge` is of the form `(u, v)` where `u` and `v`
39: (8)                     are the tail and head of the edge as determined by the traversal.
40: (8)                     For multigraphs, `edge` is of the form `(u, v, key)`, where `key` is
41: (8)                     the key of the edge. When the graph is directed, then `u` and `v`
42: (8)                     are always in the order of the actual directed edge.
43: (8)                     If orientation is not None then the edge tuple is extended to include
44: (8)                     the direction of traversal ('forward' or 'reverse') on that edge.
45: (4)                 Examples
46: (4)                 --------
47: (4)                 >>> nodes = [0, 1, 2, 3]

199: (4)                Notes
200: (4)                -----
```

```
    While this algorithm can find a minimum branching, since it isn't required
    to be spanning, the minimum branching is always from the set of negative
    weight edges which is most likely the empty set for most graphs.

        So we need the code in _init and find_optimum to successfully run edmonds algorithm.
        Responsibilities of the _init function:
        - Check that the kind argument is in {min, max} or raise a NetworkXException.
        - Transform the graph if we need a minimum arborescence/branching.
          - The current method is to map weight -> -weight. This is NOT a good approach since
            the algorithm can and does choose to ignore negative weights when creating a branching
            since that is always optimal when maximzing the weights. I think we should set the edge
            weights to be (max_weight + 1) - edge_weight.
        - Transform the graph into a MultiDiGraph, adding the partition information and potoentially
          other edge attributes if we set preserve_attrs = True.
        - Setup the buckets and union find data structures required for the algorithm.

        """
        Returns a branching from G.
        Parameters
        ----------
        attr : str
            The edge attribute used to in determining optimality.
        default : float
            The value of the edge attribute used if an edge does not have
            the attribute `attr`.
        kind : {'min', 'max'}
            The type of optimum to search for, either 'min' or 'max'.
        style : {'branching', 'arborescence'}
            If 'branching', then an optimal branching is found. If `style` is
            'arborescence', then a branching is found, such that if the
            branching is also an arborescence, then the branching is an
            optimal spanning arborescences. A given graph G need not have
            an optimal spanning arborescence.
        preserve_attrs : bool
            If True, preserve the other edge attributes of the original
            graph (that are not the one passed to `attr`)
        partition : str
            The edge attribute holding edge partition data. Used in the
            spanning arborescence iterator.
        seed : integer, random_state, or None (default)
            Indicator of random number generation state.
            See :ref:`Randomness<randomness>`.
        Returns
        -------
        H : (multi)digraph
            The branching.

class ArborescenceIterator:
    """
    Iterate over all spanning arborescences of a graph in either increasing or
    decreasing cost.
    Notes
    -----
    This iterator uses the partition scheme from [1]_ (included edges,
    excluded edges and open edges). It generates minimum spanning
    arborescences using a modified Edmonds' Algorithm which respects the
    partition of edges. For arborescences with the same weight, ties are
    broken arbitrarily.

29: (4)                 The nested tuple representation of a tree is defined
30: (4)                 recursively. The tree with one node and no edges is represented by
31: (4)                 the empty tuple, ``()``. A tree with ``k`` subtrees is represented
32: (4)                 by a tuple of length ``k`` in which each element is the nested tuple
33: (4)                 representation of a subtree.
34: (4)                 Parameters
35: (4)                 ----------
36: (4)                 T : NetworkX graph
37: (8)                     An undirected graph object representing a tree.
38: (4)                 root : node
39: (8)                     The node in ``T`` to interpret as the root of the tree.
40: (4)                 canonical_form : bool
41: (8)                     If ``True``, each tuple is sorted so that the function returns
42: (8)                     a canonical form for rooted trees. This means "lighter" subtrees
43: (8)                     will appear as nested tuples before "heavier" subtrees. In this
44: (8)                     way, each isomorphic rooted tree has the same nested tuple
45: (8)                     representation.
46: (4)                 Returns
47: (4)                 -------
48: (4)                 tuple
49: (8)                     A nested tuple representation of the tree.
50: (4)                 Notes
51: (4)                 -----
52: (4)                 This function is *not* the inverse of :func:`from_nested_tuple`; the
53: (4)                 only guarantee is that the rooted trees are isomorphic.
54: (4)                 See also
55: (4)                 --------
56: (4)                 from_nested_tuple
57: (4)                 to_prufer_sequence
58: (4)                 Examples
59: (4)                 --------
```

```
(4)                 The tree need not be a balanced binary tree::
(8)                     >>> T = nx.Graph()
(8)                     >>> T.add_edges_from([(0, 1), (0, 2), (0, 3)])
(8)                     >>> T.add_edges_from([(1, 4), (1, 5)])
(8)                     >>> T.add_edges_from([(3, 6), (3, 7)])
(8)                     >>> root = 0
(8)                     >>> nx.to_nested_tuple(T, root)
(8)                     ((((), ()), (), ((), ()))
(4)                 Continuing the above example, if ``canonical_form`` is ``True``, the
(4)                 nested tuples will be sorted::
(8)                     >>> nx.to_nested_tuple(T, root, canonical_form=True)
(8)                     ((), ((), ()), ((), ()))
(4)                 Even the path graph can be interpreted as a tree::
(8)                     >>> T = nx.path_graph(4)
(8)                     >>> root = 0
(8)                     >>> nx.to_nested_tuple(T, root)
(8)                     ((((),),),)
(4)                 """
(4)                 def _make_tuple(T, root, _parent):

(4)                 """Returns the rooted tree corresponding to the given nested tuple.
(4)                 The nested tuple representation of a tree is defined
(4)                 recursively. The tree with one node and no edges is represented by
(4)                 the empty tuple, ``()``. A tree with ``k`` subtrees is represented
(4)                 by a tuple of length ``k`` in which each element is the nested tuple
(4)                 representation of a subtree.
(4)                 Parameters
(4)                 ----------
(4)                 sequence : tuple
(8)                     A nested tuple representing a rooted tree.
(4)                 sensible_relabeling : bool
(8)                     Whether to relabel the nodes of the tree so that nodes are
(8)                     labeled in increasing order according to their breadth-first
(8)                     search order from the root node.
(4)                 Returns
(4)                 -------
(4)                 NetworkX graph
(8)                     The tree corresponding to the given nested tuple, whose root
(8)                     node is node 0. If ``sensible_labeling`` is ``True``, nodes will
(8)                     be labeled in breadth-first search order starting from the root
(8)                     node.
(4)                 Notes
(4)                 -----
(4)                 This function is *not* the inverse of :func:`to_nested_tuple`; the
(4)                 only guarantee is that the rooted trees are isomorphic.
(4)                 See also
(4)                 --------

```

```
    Examples
    --------
    Sensible relabeling ensures that the nodes are labeled from the root
    starting at 0::
        >>> balanced = ((((), ()), ((), ()))
        >>> T = nx.from_nested_tuple(balanced, sensible_relabeling=True)
        >>> edges = [(0, 1), (0, 2), (1, 3), (1, 4), (2, 5), (2, 6)]
        >>> all((u, v) in T.edges() or (v, u) in T.edges() for (u, v) in
edges)
        True
    """
    def _make_tree(sequence):
        """Recursively creates a tree from the given sequence of nested
        tuples.
        This function employs the :func:`~networkx.tree.join` function
        to recursively join subtrees into a larger tree.
        """
        if len(sequence) == 0:
            return nx.empty_graph(1)
        return nx.tree.join_trees([(_make_tree(child), 0) for child in
sequence])
    T = _make_tree(sequence)
    if sensible_relabeling:
        bfs_nodes = chain([0], (v for u, v in nx.bfs_edges(T, 0)))
        labels = {v: i for i, v in enumerate(bfs_nodes)}
        T = nx.relabel_nodes(T, labels)
    return T
@not_implemented_for("directed")
@nx._dispatchable(graphs="T")
def to_prufer_sequence(T):
    r"""Returns the Prüfer sequence of the given tree.
    A *Prüfer sequence* is a list of *n* - 2 numbers between 0 and
    *n* - 1, inclusive. The tree corresponding to a given Prüfer
    sequence can be recovered by repeatedly joining a node in the
    sequence with a node with the smallest potential degree according to
    the sequence.
    Parameters
    ----------
    T : NetworkX graph
        An undirected graph object representing a tree.
    Returns
    -------
    list
        The Prüfer sequence of the given tree.
    Raises
    ------
    NetworkXPointlessConcept
        If the number of nodes in `T` is less than two.
    NotATree
        If `T` is not a tree.
    KeyError
        If the set of nodes in `T` is not {0, …, *n* - 1}.
    Notes
    -----
    There is a bijection from labeled trees to Prüfer sequences. This
    function is the inverse of the :func:`from_prufer_sequence`
    function.
    Sometimes Prüfer sequences use nodes labeled from 1 to *n* instead
    of from 0 to *n* - 1. This function requires nodes to be labeled in
    the latter form. You can use :func:`~networkx.relabel_nodes` to
    relabel the nodes of your tree to the appropriate format.
    This implementation is from [1]_ and has a running time of
    $O(n)$.

9: (0)              def junction_tree(G):
10: (4)                 r"""Returns a junction tree of a given graph.
11: (4)                 A junction tree (or clique tree) is constructed from a (un)directed graph
G.
12: (4)                 The tree is constructed based on a moralized and triangulated version of
```

```
G.
13: (4)                 The tree's nodes consist of maximal cliques and sepsets of the revised
graph.
14: (4)                 The sepset of two cliques is the intersection of the nodes of these
cliques,
15: (4)                 e.g. the sepset of (A,B,C) and (A,C,E,F) is (A,C). These nodes are often
called
16: (4)                 "variables" in this literature. The tree is bipartite with each sepset
17: (4)                 connected to its two cliques.
18: (4)                 Junction Trees are not unique as the order of clique consideration
determines
19: (4)                 which sepsets are included.
20: (4)                 The junction tree algorithm consists of five steps [1]_:
21: (4)                 1. Moralize the graph
22: (4)                 2. Triangulate the graph
23: (4)                 3. Find maximal cliques
24: (4)                 4. Build the tree from cliques, connecting cliques with shared
25: (7)                    nodes, set edge-weight to number of shared variables
26: (4)                 5. Find maximum spanning tree

(0)             ):
(4)                 """Generate edges in a minimum spanning forest of an undirected
(4)                 weighted graph.
(4)                 A minimum spanning tree is a subgraph of the graph (a tree)
(4)                 with the minimum sum of edge weights.  A spanning forest is a
(4)                 union of the spanning trees for each connected component of the graph.
(4)                 Parameters
(4)                 ----------
(4)                 G : undirected Graph
(7)                    An undirected graph. If `G` is connected, then the algorithm finds a
(7)                    spanning tree. Otherwise, a spanning forest is found.
(4)                 algorithm : string
(7)                    The algorithm to use when finding a minimum spanning tree. Valid
(7)                    choices are 'kruskal', 'prim', or 'boruvka'. The default is 'kruskal'.
(4)                 weight : string
(7)                    Edge data key to use for weight (default 'weight').
(4)                 keys : bool
(7)                    Whether to yield edge key in multigraphs in addition to the edge.
(7)                    If `G` is not a multigraph, this is ignored.
(4)                 data : bool, optional
(7)                    If True yield the edge data along with the edge.
(4)                 ignore_nan : bool (default: False)
(8)                     If a NaN is found as an edge weight normally an exception is raised.
(8)                     If `ignore_nan is True` then that edge is ignored instead.
(4)                 Returns
(4)                 -------
(4)                 edges : iterator
(7)                    An iterator over edges in a maximum spanning tree of `G`.
(7)                    Edges connecting nodes `u` and `v` are represented as tuples:
(7)                    `(u, v, k, d)` or `(u, v, k)` or `(u, v, d)` or `(u, v)`
(7)                    If `G` is a multigraph, `keys` indicates whether the edge key `k` will
(7)                    be reported in the third position in the edge tuple. `data` indicates
(7)                    whether the edge datadict `d` will appear at the end of the edge tuple.
(7)                    If `G` is not a multigraph, the tuples are `(u, v, d)` if `data` is True
(7)                    or `(u, v)` if `data` is False.
(4)                 Examples
(4)                 --------
(4)                 >>> from networkx.algorithms import tree
(4)                 Find minimum spanning edges by Kruskal's algorithm
(4)                 >>> G = nx.cycle_graph(4)

@nx._dispatchable(preserve_all_attrs=True, returns_graph=True)
def partition_spanning_tree(
    G, minimum=True, weight="weight", partition="partition", ignore_nan=False
):
    """
    Find a spanning tree while respecting a partition of edges.
    Edges can be flagged as either `INCLUDED` which are required to be in the
    returned tree, `EXCLUDED`, which cannot be in the returned tree and `OPEN`.
    This is used in the SpanningTreeIterator to create new partitions following
    the algorithm of Sörensen and Janssens [1]_.
    Parameters
    ----------
    G : undirected graph
        An undirected graph.
    minimum : bool (default: True)
        Determines whether the returned tree is the minimum spanning tree of
        the partition of the maximum one.
    weight : str
        Data key to use for edge weights.
    partition : str
        The key for the edge attribute containing the partition
        data on the graph. Edges can be included, excluded or open using the
        `EdgePartition` enum.
    ignore_nan : bool (default: False)
        If a NaN is found as an edge weight normally an exception is raised.
        If `ignore_nan is True` then that edge is ignored instead.
    Returns
    -------
    G : NetworkX Graph
        A minimum spanning tree using all of the included edges in the graph and
        none of the excluded edges.
    References
    ----------
    .. [1] G.K. Janssens, K. Sörensen, An algorithm to generate all spanning
           trees in order of increasing cost, Pesquisa Operacional, 2005-08,

def maximum_spanning_tree(G, weight="weight", algorithm="kruskal", ignore_nan=False):
    """Returns a maximum spanning tree or forest on an undirected graph `G`.
    Parameters
    ----------
```

```
    G : undirected graph
        An undirected graph. If `G` is connected, then the algorithm finds a
        spanning tree. Otherwise, a spanning forest is found.
    weight : str
       Data key to use for edge weights.
    algorithm : string
       The algorithm to use when finding a maximum spanning tree. Valid
       choices are 'kruskal', 'prim', or 'boruvka'. The default is
       'kruskal'.
    ignore_nan : bool (default: False)
        If a NaN is found as an edge weight normally an exception is raised.
        If `ignore_nan is True` then that edge is ignored instead.
    Returns
    -------
    G : NetworkX Graph
       A maximum spanning tree or forest.
    Examples
    --------
    >>> G = nx.cycle_graph(4)
    >>> G.add_edge(0, 3, weight=2)
    >>> T = nx.maximum_spanning_tree(G)
    >>> sorted(T.edges(data=True))
    [(0, 1, {}), (0, 3, {'weight': 2}), (1, 2, {})]
    Notes
    -----
    For Borůvka's algorithm, each edge must have a weight attribute, and
    each edge weight must be distinct.
    For the other algorithms, if the graph edges do not have a weight
    attribute a default weight of 1 will be used.
    There may be more than one tree with the same minimum or maximum weight.
    See :mod:`networkx.tree.recognition` for more detailed definitions.
    Isolated nodes with self-loops are in the tree as edgeless isolated nodes.

@py_random_state(3)
@nx._dispatchable(preserve_edge_attrs=True, returns_graph=True)
def random_spanning_tree(G, weight=None, *, multiplicative=True, seed=None):
    """
    Sample a random spanning tree using the edges weights of `G`.
    This function supports two different methods for determining the
    probability of the graph. If ``multiplicative=True``, the probability
    is based on the product of edge weights, and if ``multiplicative=False``
    it is based on the sum of the edge weight. However, since it is
    easier to determine the total weight of all spanning trees for the
    multiplicative version, that is significantly faster and should be used if
    possible. Additionally, setting `weight` to `None` will cause a spanning tree

    to be selected with uniform probability.
    The function uses algorithm A8 in [1]_ .
    Parameters
    ----------
    G : nx.Graph
        An undirected version of the original graph.
    weight : string
        The edge key for the edge attribute holding edge weight.
    multiplicative : bool, default=True
        If `True`, the probability of each tree is the product of its edge weight

        over the sum of the product of all the spanning trees in the graph. If
        `False`, the probability is the sum of its edge weight over the sum of
        the sum of weights for all spanning trees in the graph.
```

```
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
    Returns
    -------
    nx.Graph
        A spanning tree using the distribution defined by the weight of the tree.
    References
    ----------
    .. [1] V. Kulkarni, Generating random combinatorial objects, Journal of
       Algorithms, 11 (1990), pp. 185–207
    """
    def find_node(merged_nodes, node):
        """
        We can think of clusters of contracted nodes as having one
        representative in the graph. Each node which is not in merged_nodes
        is still its own representative. Since a representative can be later
        contracted, we need to recursively search though the dict to find
        the final representative, but once we know it we can use path
        compression to speed up the access of the representative for next time.
        This cannot be replaced by the standard NetworkX union_find since that
        data structure will merge nodes with less representing nodes into the
        one with more representing nodes but this function requires we merge
        them using the order that contract_edges contracts using.
        Parameters
        ----------
        merged_nodes : dict
            The dict storing the mapping from node to representative
        node
            The node whose representative we seek
        Returns
        -------
        The representative of the `node`
        """

(0)             @nx._dispatchable(edge_attrs="weight")
(0)             def number_of_spanning_trees(G, *, root=None, weight=None):
(4)                 """Returns the number of spanning trees in `G`.
(4)                 A spanning tree for an undirected graph is a tree that connects
(4)                 all nodes in the graph. For a directed graph, the analog of a
(4)                 spanning tree is called a (spanning) arborescence. The arborescence
(4)                 includes a unique directed path from the `root` node to each other node.
(4)                 The graph must be weakly connected, and the root must be a node
(4)                 that includes all nodes as successors [3]_. Note that to avoid
(4)                 discussing sink-roots and reverse-arborescences, we have reversed
(4)                 the edge orientation from [3]_ and use the in-degree laplacian.
(4)                 This function (when `weight` is `None`) returns the number of
(4)                 spanning trees for an undirected graph and the number of
(4)                 arborescences from a single root node for a directed graph.
(4)                 When `weight` is the name of an edge attribute which holds the
(4)                 weight value of each edge, the function returns the sum over
(4)                 all trees of the multiplicative weight of each tree. That is,
(4)                 the weight of the tree is the product of its edge weights.
(4)                 Kirchoff's Tree Matrix Theorem states that any cofactor of the
(4)                 Laplacian matrix of a graph is the number of spanning trees in the
(4)                 graph. (Here we use cofactors for a diagonal entry so that the
(4)                 cofactor becomes the determinant of the matrix with one row
(4)                 and its matching column removed.) For a weighted Laplacian matrix,
(4)                 the cofactor is the sum across all spanning trees of the
(4)                 multiplicative weight of each tree. That is, the weight of each
(4)                 tree is the product of its edge weights. The theorem is also
(4)                 known as Kirchhoff's theorem [1]_ and the Matrix-Tree theorem [2]_.
(4)                 For directed graphs, a similar theorem (Tutte's Theorem) holds with
(4)                 the cofactor chosen to be the one with row and column removed that
(4)                 correspond to the root. The cofactor is the number of arborescences
(4)                 with the specified node as root. And the weighted version gives the
(4)                 sum of the arborescence weights with root `root`. The arborescence
(4)                 weight is the product of its edge weights.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX graph
(4)                 root : node
(7)                    A node in the directed graph `G` that has all nodes as descendants.
(7)                    (This is ignored for undirected graphs.)
(4)                 weight : string or None, optional (default=None)
(8)                     The name of the edge attribute holding the edge weight.
(8)                     If `None`, then each edge is assumed to have a weight of 1.
(4)                 Returns
(4)                 -------
(4)                 Number
(8)                     Undirected graphs:
(12)                        The number of spanning trees of the graph `G`.
(12)                        Or the sum of all spanning tree weights of the graph `G`
(12)                        where the weight of a tree is the product of its edge weights.
(8)                     Directed graphs:
(12)                        The number of arborescences of `G` rooted at node `root`.
(12)                        Or the sum of all arborescence weights of the graph `G` with
(12)                        specified root where the weight of an arborescence is the product
```

32: (4)                 rooted_trees : list
33: (8)                     A list of pairs in which each left element is a NetworkX graph
34: (8)                     object representing a tree and each right element is the root
35: (8)                     node of that tree. The nodes of these trees will be relabeled to
36: (8)                     integers.
37: (4)                 label_attribute : str
38: (8)                     If provided, the old node labels will be stored in the new tree
39: (8)                     under this node attribute. If not provided, the original labels
40: (8)                     of the nodes in the input trees are not stored.
41: (4)                 first_label : int, optional (default=0)
42: (8)                     Specifies the label for the new root node. If provided, the root node
of the joined tree
43: (8)                     will have this label. If not provided, the root node will default to a
label of 0.
44: (4)                 Returns
45: (4)                 -------
46: (4)                 NetworkX graph
47: (8)                     The rooted tree resulting from joining the provided `rooted_trees`.
The new tree has a root node
48: (8)                     labeled as specified by `first_label` (defaulting to 0 if not
provided). Subtrees from the input
49: (8)                     `rooted_trees` are attached to this new root node. Each non-root node,
if the `label_attribute`
50: (8)                     is provided, has an attribute that indicates the original label of the
node in the input tree.
51: (4)                 Notes
52: (4)                 -----
53: (4)                 Trees are stored in NetworkX as NetworkX Graphs. There is no specific
54: (4)                 enforcement of the fact that these are trees. Testing for each tree
55: (4)                 can be done using :func:`networkx.is_tree`.
56: (4)                 Graph, edge, and node attributes are propagated from the given
57: (4)                 rooted trees to the created tree. If there are any overlapping graph
58: (4)                 attributes, those from later trees will overwrite those from earlier
59: (4)                 trees in the tuple of positional arguments.
60: (4)                 Examples
61: (4)                 --------
62: (4)                 Join two full balanced binary trees of height *h* to get a full
63: (4)                 balanced binary tree of depth *h* + 1::
64: (8)                     >>> h = 4
65: (8)                     >>> left = nx.balanced_tree(2, h)
66: (8)                     >>> right = nx.balanced_tree(2, h)
67: (8)                     >>> joined_tree = nx.join([(left, 0), (right, 0)])
68: (8)                     >>> nx.is_isomorphic(joined_tree, nx.balanced_tree(2, h + 1))
```

```
69: (8)                     True
70: (4)                 """

```
1: (0)              """
2: (0)              Recognition Tests
3: (0)              =================
4: (0)              A *forest* is an acyclic, undirected graph, and a *tree* is a connected
forest.
5: (0)              Depending on the subfield, there are various conventions for generalizing
these
6: (0)              definitions to directed graphs.
7: (0)              In one convention, directed variants of forest and tree are defined in an
8: (0)              identical manner, except that the direction of the edges is ignored. In
effect,
9: (0)              each directed edge is treated as a single undirected edge. Then, additional
10: (0)             restrictions are imposed to define *branchings* and *arborescences*.
11: (0)             In another convention, directed variants of forest and tree correspond to
12: (0)             the previous convention's branchings and arborescences, respectively. Then two
13: (0)             new terms, *polyforest* and *polytree*, are defined to correspond to the other
14: (0)             convention's forest and tree.
15: (0)             Summarizing::
16: (3)                +-----------------------------+
17: (3)                | Convention A | Convention B |
18: (3)                +=============================+
19: (3)                | forest       | polyforest   |
20: (3)                | tree         | polytree     |
21: (3)                | branching    | forest       |
22: (3)                | arborescence | tree         |
23: (3)                +-----------------------------+
24: (0)             Each convention has its reasons. The first convention emphasizes definitional
25: (0)             similarity in that directed forests and trees are only concerned with
26: (0)             acyclicity and do not have an in-degree constraint, just as their undirected
27: (0)             counterparts do not. The second convention emphasizes functional similarity
28: (0)             in the sense that the directed analog of a spanning tree is a spanning
29: (0)             arborescence. That is, take any spanning tree and choose one node as the root.
30: (0)             Then every edge is assigned a direction such there is a directed path from the
31: (0)             root to every other node. The result is a spanning arborescence.
```

```
 32: (0)             NetworkX follows convention "A". Explicitly, these are:
 33: (0)             undirected forest
 34: (3)                An undirected graph with no undirected cycles.
 35: (0)             undirected tree
 36: (3)                A connected, undirected forest.
 37: (0)             directed forest
 38: (3)                A directed graph with no undirected cycles. Equivalently, the underlying
 39: (3)                graph structure (which ignores edge orientations) is an undirected forest.
 40: (3)                In convention B, this is known as a polyforest.
 41: (0)             directed tree
 42: (3)                A weakly connected, directed forest. Equivalently, the underlying graph
 43: (3)                structure (which ignores edge orientations) is an undirected tree. In
 44: (3)                convention B, this is known as a polytree.
 45: (0)             branching
 46: (3)                A directed forest with each node having, at most, one parent. So the
maximum
 47: (3)                in-degree is equal to 1. In convention B, this is known as a forest.
 48: (0)             arborescence
 49: (3)                A directed tree with each node having, at most, one parent. So the maximum
 50: (3)                in-degree is equal to 1. In convention B, this is known as a tree.
 51: (0)             For trees and arborescences, the adjective "spanning" may be added to
designate
 52: (0)             that the graph, when considered as a forest/branching, consists of a single
 53: (0)             tree/arborescence that includes all nodes in the graph. It is true, by
 54: (0)             definition, that every tree/arborescence is spanning with respect to the nodes
 55: (0)             that define the tree/arborescence and so, it might seem redundant to introduce
 56: (0)             the notion of "spanning". However, the nodes may represent a subset of
 57: (0)             nodes from a larger graph, and it is in this context that the term "spanning"
 58: (0)             becomes a useful notion.
 59: (0)             """

55: (4)                 Base class for directed graphs.
56: (4)                 A DiGraph stores nodes and edges with optional data, or attributes.
57: (4)                 DiGraphs hold directed edges.  Self loops are allowed but multiple
58: (4)                 (parallel) edges are not.
59: (4)                 Nodes can be arbitrary (hashable) Python objects with optional
60: (4)                 key/value attributes. By convention `None` is not used as a node.
61: (4)                 Edges are represented as links between nodes with optional
62: (4)                 key/value attributes.
63: (4)                 Parameters
64: (4)                 ----------
65: (4)                 incoming_graph_data : input graph (optional, default: None)
66: (8)                     Data to initialize graph. If None (default) an empty
67: (8)                     graph is created.  The data can be any format that is supported
68: (8)                     by the to_networkx_graph() function, currently including edge list,
69: (8)                     dict of dicts, dict of lists, NetworkX graph, 2D NumPy array, SciPy
70: (8)                     sparse matrix, or PyGraphviz graph.
71: (4)                 attr : keyword arguments, optional (default= no attributes)
72: (8)                     Attributes to add to graph as key=value pairs.
73: (4)                 See Also
74: (4)                 --------
75: (4)                 Graph
76: (4)                 MultiGraph
77: (4)                 MultiDiGraph
78: (4)                 Examples
79: (4)                 --------
80: (4)                 Create an empty graph structure (a "null graph") with no nodes and
81: (4)                 no edges.
82: (4)                 >>> G = nx.DiGraph()
```

```
(4)                 G can be grown in several ways.
(4)                 **Nodes:**
(4)                 Add one node at a time:
(4)                 >>> G.add_node(1)
(4)                 Add the nodes from any container (a list, dict, set or
(4)                 even the lines from a file or the nodes from another graph).
(4)                 >>> G.add_nodes_from([2, 3])
(4)                 >>> G.add_nodes_from(range(100, 110))
(4)                 >>> H = nx.path_graph(10)
(4)                 >>> G.add_nodes_from(H)
(4)                 In addition to strings and integers any hashable Python object
(4)                 (except None) can represent a node, e.g. a customized node object,
(4)                 or even another Graph.
(4)                 >>> G.add_node(H)
(4)                 **Edges:**
(4)                 G can also be grown by adding edges.
(4)                 Add one edge,
(4)                 >>> G.add_edge(1, 2)
(4)                 a list of edges,
(4)                 >>> G.add_edges_from([(1, 2), (1, 3)])
(4)                 or a collection of edges,
(4)                 >>> G.add_edges_from(H.edges)
(4)                 If some edges connect nodes not yet in the graph, the nodes
(4)                 are added automatically.  There are no errors when adding
(4)                 nodes or edges that already exist.
(4)                 **Attributes:**
(4)                 Each graph, node, and edge can hold key/value attribute pairs
(4)                 in an associated attribute dictionary (the keys must be hashable).
(4)                 By default these are empty, but can be added or changed using
(4)                 add_edge, add_node or direct manipulation of the attribute
(4)                 dictionaries named graph, node and edge respectively.
(4)                 >>> G = nx.DiGraph(day="Friday")
(4)                 >>> G.graph
(4)                 {'day': 'Friday'}
(4)                 Add node attributes using add_node(), add_nodes_from() or G.nodes
(4)                 >>> G.add_node(1, time="5pm")
(4)                 >>> G.add_nodes_from([3], time="2pm")
(4)                 >>> G.nodes[1]
(4)                 {'time': '5pm'}
(4)                 >>> G.nodes[1]["room"] = 714
(4)                 >>> del G.nodes[1]["room"]  # remove attribute
(4)                 >>> list(G.nodes(data=True))
(4)                 [(1, {'time': '5pm'}), (3, {'time': '2pm'})]
(4)                 Add edge attributes using add_edge(), add_edges_from(), subscript
(4)                 notation, or G.edges.
(4)                 >>> G.add_edge(1, 2, weight=4.7)
(4)                 >>> G.add_edges_from([(3, 4), (4, 5)], color="red")
(4)                 >>> G.add_edges_from([(1, 2, {"color": "blue"}), (2, 3, {"weight": 8})])
(4)                 >>> G[1][2]["weight"] = 4.7
(4)                 >>> G.edges[1, 2]["weight"] = 4
(4)                 Warning: we protect the graph data structure by making `G.edges[1, 2]` a
(4)                 read-only dict-like structure. However, you can assign to attributes
(4)                 in e.g. `G.edges[1, 2]`. Thus, use 2 sets of brackets to add/change
(4)                 data attributes: `G.edges[1, 2]['weight'] = 4`
(4)                 (For multigraphs: `MG.edges[u, v, key][name] = value`).
(4)                 **Shortcuts:**
(4)                 Many common graph features allow python syntax to speed reporting.
(4)                 >>> 1 in G  # check if node in graph
(4)                 True
(4)                 >>> [n for n in G if n < 3]  # iterate through nodes
(4)                 [1, 2]
(4)                 >>> len(G)  # number of nodes in graph
(4)                 5
(4)                 Often the best way to traverse all edges of a graph is via the neighbors.
(4)                 The neighbors are reported as an adjacency-dict `G.adj` or `G.adjacency()`
(4)                 >>> for n, nbrsdict in G.adjacency():
(4)                 ...     for nbr, eattr in nbrsdict.items():
(4)                 ...         if "weight" in eattr:
(4)                 ...             # Do something useful with the edges
```

```
(4)                 ...             pass
(4)                 But the edges reporting object is often more convenient:
(4)                 >>> for u, v, weight in G.edges(data="weight"):
(4)                 ...     if weight is not None:
(4)                 ...         # Do something useful with the edges
(4)                 ...         pass
(4)                 **Reporting:**
(4)                 Simple graph information is obtained using object-attributes and methods.
(4)                 Reporting usually provides views instead of containers to reduce memory
(4)                 usage. The views update as the graph is updated similarly to dict-views.
(4)                 The objects `nodes`, `edges` and `adj` provide access to data attributes
(4)                 via lookup (e.g. `nodes[n]`, `edges[u, v]`, `adj[u][v]`) and iteration
(4)                 (e.g. `nodes.items()`, `nodes.data('color')`,
(4)                 `nodes.data('color', default='blue')` and similarly for `edges`)
(4)                 Views exist for `nodes`, `edges`, `neighbors()`/`adj` and `degree`.
(4)                 For details on these and other miscellaneous methods, see below.
(4)                 **Subclasses (Advanced):**
(4)                 The Graph class uses a dict-of-dict-of-dict data structure.
(4)                 The outer dict (node_dict) holds adjacency information keyed by node.
(4)                 The next dict (adjlist_dict) represents the adjacency information and
holds
(4)                 edge data keyed by neighbor.  The inner dict (edge_attr_dict) represents
(4)                 the edge data and holds edge attribute values keyed by attribute names.
(4)                 Each of these three dicts can be replaced in a subclass by a user defined
(4)                 dict-like object. In general, the dict-like features should be
(4)                 maintained but extra features can be added. To replace one of the
(4)                 dicts create a new graph class by changing the class(!) variable
(4)                 holding the factory for that dict-like structure. The variable names are
(4)                 node_dict_factory, node_attr_dict_factory, adjlist_inner_dict_factory,
(4)                 adjlist_outer_dict_factory, edge_attr_dict_factory and
graph_attr_dict_factory.
(4)                 node_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the dict containing node
(8)                     attributes, keyed by node id.
(8)                     It should require no arguments and return a dict-like object
(4)                 node_attr_dict_factory: function, (default: dict)
(8)                     Factory function to be used to create the node attribute
(8)                     dict which holds attribute values keyed by attribute name.
(8)                     It should require no arguments and return a dict-like object
(4)                 adjlist_outer_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the outer-most dict
(8)                     in the data structure that holds adjacency info keyed by node.
(8)                     It should require no arguments and return a dict-like object.
(4)                 adjlist_inner_dict_factory : function, optional (default: dict)
(8)                     Factory function to be used to create the adjacency list
(8)                     dict which holds edge data keyed by neighbor.
(8)                     It should require no arguments and return a dict-like object
(4)                 edge_attr_dict_factory : function, optional (default: dict)
(8)                     Factory function to be used to create the edge attribute
(8)                     dict which holds attribute values keyed by attribute name.
(8)                     It should require no arguments and return a dict-like object.
(4)                 graph_attr_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the graph attribute
(8)                     dict which holds attribute values keyed by attribute name.
(8)                     It should require no arguments and return a dict-like object.
(4)                 Typically, if your extension doesn't impact the data structure all
(4)                 methods will inherited without issue except: `to_directed/to_undirected`.
(4)                 By default these methods create a DiGraph/Graph class and you probably
(4)                 want them to create your extension of a DiGraph/Graph. To facilitate
(4)                 this we define two class variables that you can set in your subclass.
(4)                 to_directed_class : callable, (default: DiGraph or MultiDiGraph)
(8)                     Class to create a new graph structure in the `to_directed` method.
(8)                     If `None`, a NetworkX class (DiGraph or MultiDiGraph) is used.
(4)                 to_undirected_class : callable, (default: Graph or MultiGraph)
(8)                     Class to create a new graph structure in the `to_undirected` method.
(8)                     If `None`, a NetworkX class (Graph or MultiGraph) is used.
(4)                 **Subclassing Example**
(4)                 Create a low memory graph class that effectively disallows edge
(4)                 attributes by using a single attribute dict for all edges.
```

```
    This reduces the memory used, but you lose edge attributes.
    >>> class ThinGraph(nx.Graph):
    ...     all_edge_dict = {"weight": 1}
    ...
    ...     def single_edge_dict(self):
    ...         return self.all_edge_dict
    ...
    ...     edge_attr_dict_factory = single_edge_dict
    >>> G = ThinGraph()
    >>> G.add_edge(2, 1)
    >>> G[2][1]
    {'weight': 1}
    >>> G.add_edge(2, 2)
    >>> G[2][1] is G[2][2]
    True
    """
    _adj = _CachedPropertyResetterAdjAndSucc()  # type: ignore[assignment]
    _succ = _adj  # type: ignore[has-type]
    _pred = _CachedPropertyResetterPred()
    def __init__(self, incoming_graph_data=None, **attr):
        """Initialize a graph with edges, name, or graph attributes.
        Parameters
        ----------
        incoming_graph_data : input graph (optional, default: None)
            Data to initialize graph.  If None (default) an empty
            graph is created.  The data can be an edge list, or any
            NetworkX graph object.  If the corresponding optional Python
            packages are installed the data can also be a 2D NumPy array, a
            SciPy sparse array, or a PyGraphviz graph.
        attr : keyword arguments, optional (default= no attributes)
            Attributes to add to graph as key=value pairs.
        See Also
        --------
        convert
        Examples
        --------
        >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> G = nx.Graph(name="my graph")
        >>> e = [(1, 2), (2, 3), (3, 4)]  # list of edges
        >>> G = nx.Graph(e)
        Arbitrary graph attribute pairs (key=value) may be assigned
        >>> G = nx.Graph(e, day="Friday")
        >>> G.graph
        {'day': 'Friday'}
        """
        self.graph = self.graph_attr_dict_factory()  # dictionary for graph attributes
        self._node = self.node_dict_factory()  # dictionary for node attr

        >>> G.add_node(3, weight=0.4, UTM=("13S", 382871, 3972649))
        Notes
        -----
        A hashable object is one that can be used as a key in a Python
        dictionary. This includes strings, numbers, tuples of strings
        and numbers, etc.
        On many platforms hashable items also include mutables such as
        NetworkX Graphs, though one should be careful that the hash
        doesn't change on mutables.

    def add_edges_from(self, ebunch_to_add, **attr):
        """Add all the edges in ebunch_to_add.
        Parameters
        ----------
        ebunch_to_add : container of edges
            Each edge given in the container will be added to the
            graph. The edges must be given as 2-tuples (u, v) or
            3-tuples (u, v, d) where d is a dictionary containing edge data.
        attr : keyword arguments, optional
            Edge data (or labels or objects) can be assigned using
            keyword arguments.
        See Also
        --------
        add_edge : add a single edge
        add_weighted_edges_from : convenient way to add weighted edges
        Notes
        -----
        Adding the same edge twice has no effect but any edge data
        will be updated when each duplicate edge is added.
        Edge attributes specified in an ebunch take precedence over
        attributes specified via keyword arguments.
        When adding edges from an iterator over the graph you are changing,
        a `RuntimeError` can be raised with message:
        `RuntimeError: dictionary changed size during iteration`. This
        happens when the graph's underlying dictionary is modified during
        iteration. To avoid this error, evaluate the iterator into a separate
        object, e.g. by using `list(iterator_of_edges)`, and pass this
        object to `G.add_edges_from`.
        Examples
        --------
        >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> G.add_edges_from([(0, 1), (1, 2)])  # using a list of edge tuples
        >>> e = zip(range(0, 3), range(1, 4))
        >>> G.add_edges_from(e)  # Add the path graph 0-1-2-3
        Associate data to edges
        >>> G.add_edges_from([(1, 2), (2, 3)], weight=3)
        >>> G.add_edges_from([(3, 4), (1, 4)], label="WN2898")
        Evaluate an iterator over a graph if using it to modify the same graph
        >>> G = nx.DiGraph([(1, 2), (2, 3), (3, 4)])
        >>> # Grow graph by one new node, adding edges to all existing nodes.
        >>> # wrong way - will raise RuntimeError
        >>> # G.add_edges_from(((5, n) for n in G.nodes))
        >>> # right way - note that there will be no self-edge for node 5
        >>> G.add_edges_from(list((5, n) for n in G.nodes))
        """

(8)                     nbunch : single node, container, or all nodes (default= all nodes)
(12)                        The view will only report edges incident to these nodes.
(8)                     data : string or bool, optional (default=False)
(12)                        The edge attribute returned in 3-tuple (u, v, ddict[data]).
(12)                        If True, return edge attribute dict in 3-tuple (u, v, ddict).
(12)                        If False, return 2-tuple (u, v).
(8)                     default : value, optional (default=None)
(12)                        Value used for edges that don't have the requested attribute.
(12)                        Only relevant if data is not True or False.
(8)                     Returns
(8)                     -------
(8)                     in_edges : InEdgeView or InEdgeDataView
(12)                        A view of edge attributes, usually it iterates over (u, v)
(12)                        or (u, v, d) tuples of edges, but can also be used for
(12)                        attribute lookup as `edges[u, v]['foo']`.
(8)                     Examples
(8)                     --------
(8)                     >>> G = nx.DiGraph()
(8)                     >>> G.add_edge(1, 2, color="blue")
```

```
(8)                 >>> G.in_edges()
(8)                 InEdgeView([(1, 2)])
(8)                 >>> G.in_edges(nbunch=2)
(8)                 InEdgeDataView([(1, 2)])

        return True
    def to_undirected(self, reciprocal=False, as_view=False):
        """Returns an undirected representation of the digraph.
        Parameters
        ----------
        reciprocal : bool (optional)
          If True only keep edges that appear in both directions
          in the original digraph.
        as_view : bool (optional, default=False)
          If True return an undirected view of the original directed graph.
        Returns
        -------
        G : Graph
            An undirected graph with the same name and nodes and
            with edge (u, v, data) if either (u, v, data) or (v, u, data)
            is in the digraph.  If both edges exist in digraph and
            their edge data is different, only one edge is created
            with an arbitrary choice of which edge data to use.
            You must check and correct for this manually if desired.
        See Also
        --------
        Graph, copy, add_edge, add_edges_from
        Notes
        -----
        If edges in both directions (u, v) and (v, u) exist in the
        graph, attributes for the new undirected edge will be a combination of
        the attributes of the directed edges.  The edge data is updated
        in the (arbitrary) order that the edges are encountered.  For
        more customized control of the edge attributes use add_edge().
        This returns a "deepcopy" of the edge, node, and
        graph attributes which attempts to completely copy
        all of the data and references.
        This is in contrast to the similar G=DiGraph(D) which returns a
        shallow copy of the data.
        See the Python copy module for more information on shallow
        and deep copies, https://docs.python.org/3/library/copy.html.
        Warning: If you have subclassed DiGraph to use dict-like objects
        in the data structure, those changes do not transfer to the
        Graph created by this method.
        Examples
        --------
        >>> G = nx.path_graph(2)  # or MultiGraph, etc
        >>> H = G.to_directed()
        >>> list(H.edges)
        [(0, 1), (1, 0)]
        >>> G2 = H.to_undirected()
        >>> list(G2.edges)
        [(0, 1)]
        """

(4)             -----
(4)             subgraph(G) calls G.subgraph()
(4)             """
(4)             return G.subgraph(nbunch)
(0)         def induced_subgraph(G, nbunch):
(4)             """Returns a SubGraph view of `G` showing only nodes in nbunch.
(4)             The induced subgraph of a graph on a set of nodes N is the
(4)             graph with nodes N and edges from G which have both ends in N.
(4)             Parameters
(4)             ----------
(4)             G : NetworkX Graph
(4)             nbunch : node, container of nodes or None (for all nodes)
(4)             Returns
(4)             -------
(4)             subgraph : SubGraph View
(8)                 A read-only view of the subgraph in `G` induced by the nodes.
(8)                 Changes to the graph `G` will be reflected in the view.
(4)             Notes
```

```
(4)                 -----
(4)                 To create a mutable subgraph with its own copies of nodes
(4)                 edges and attributes use `subgraph.copy()` or `Graph(subgraph)`
(4)                 For an inplace reduction of a graph to a subgraph you can remove nodes:
(4)                 `G.remove_nodes_from(n in G if n not in set(nbunch))`
(4)                 If you are going to compute subgraphs of your subgraphs you could
(4)                 end up with a chain of views that can be very slow once the chain
(4)                 has about 15 views in it. If they are all induced subgraphs, you
(4)                 can short-cut the chain by making them all subgraphs of the original
(4)                 graph. The graph class method `G.subgraph` does this when `G` is
(4)                 a subgraph. In contrast, this function allows you to choose to build
(4)                 chains or not, as you wish. The returned subgraph is a view on `G`.
(4)                 Examples
(4)                 --------
(4)                 >>> G = nx.path_graph(4)  # or DiGraph, MultiGraph, MultiDiGraph, etc
(4)                 >>> H = nx.induced_subgraph(G, [0, 1, 3])
(4)                 >>> list(H.edges)
(4)                 [(0, 1)]
(4)                 >>> list(H.nodes)
(4)                 [0, 1, 3]
(4)                 """
(4)                 induced_nodes = nx.filters.show_nodes(G.nbunch_iter(nbunch))
(4)                 return nx.subgraph_view(G, filter_node=induced_nodes)
(0)             def edge_subgraph(G, edges):
(4)                 """Returns a view of the subgraph induced by the specified edges.
(4)                 The induced subgraph contains each edge in `edges` and each
(4)                 node incident to any of those edges.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX Graph
(4)                 edges : iterable
(8)                     An iterable of edges. Edges not present in `G` are ignored.
(4)                 Returns
(4)                 -------
(4)                 subgraph : SubGraph View
(8)                     A read-only edge-induced subgraph of `G`.
(8)                     Changes to `G` are reflected in the view.
(4)                 Notes
(4)                 -----
(4)                 To create a mutable subgraph with its own copies of nodes
(4)                 edges and attributes use `subgraph.copy()` or `Graph(subgraph)`
(4)                 If you create a subgraph of a subgraph recursively you can end up
(4)                 with a chain of subgraphs that becomes very slow with about 15
(4)                 nested subgraph views. Luckily the edge_subgraph filter nests
(4)                 nicely so you can use the original graph as G in this function
(4)                 to avoid chains. We do not rule out chains programmatically so
(4)                 that odd cases like an `edge_subgraph` of a `restricted_view`
(4)                 can be created.
(4)                 Examples
(4)                 --------
(4)                 >>> G = nx.path_graph(5)
(4)                 >>> H = G.edge_subgraph([(0, 1), (3, 4)])
(4)                 >>> list(H.nodes)
(4)                 [0, 1, 3, 4]
(4)                 >>> list(H.edges)
(4)                 [(0, 1), (3, 4)]
(4)                 """

(8)                     What the node attribute should be set to.  If `values` is
(8)                     not a dictionary, then it is treated as a single attribute value
(8)                     that is then applied to every node in `G`.  This means that if
(8)                     you provide a mutable object, like a list, updates to that object
(8)                     will be reflected in the node attribute for every node.
(8)                     The attribute name will be `name`.
(8)                     If `values` is a dict or a dict of dict, it should be keyed
(8)                     by node to either an attribute value or a dict of attribute key/value
(8)                     pairs used to update the node's attributes.
(4)                 name : string (optional, default=None)
(8)                     Name of the node attribute to set if values is a scalar.
(4)                 Examples
(4)                 --------
(4)                 After computing some property of the nodes of a graph, you may want
(4)                 to assign a node attribute to store the value of that property for
(4)                 each node::
(8)                     >>> G = nx.path_graph(3)
(8)                     >>> bb = nx.betweenness_centrality(G)
(8)                     >>> isinstance(bb, dict)
(8)                     True
(8)                     >>> nx.set_node_attributes(G, bb, "betweenness")
(8)                     >>> G.nodes[1]["betweenness"]
(8)                     1.0
(4)                 If you provide a list as the second argument, updates to the list
(4)                 will be reflected in the node attribute for each node::
(8)                     >>> G = nx.path_graph(3)
(8)                     >>> labels = []
(8)                     >>> nx.set_node_attributes(G, labels, "labels")
(8)                     >>> labels.append("foo")
(8)                     >>> G.nodes[0]["labels"]
(8)                     ['foo']
(8)                     >>> G.nodes[1]["labels"]
(8)                     ['foo']
(8)                     >>> G.nodes[2]["labels"]
(8)                     ['foo']
(4)                 If you provide a dictionary of dictionaries as the second argument,
(4)                 the outer dictionary is assumed to be keyed by node to an inner
(4)                 dictionary of node attributes for that node::
(8)                     >>> G = nx.path_graph(3)
(8)                     >>> attrs = {0: {"attr1": 20, "attr2": "nothing"}, 1: {"attr2": 3}}
(8)                     >>> nx.set_node_attributes(G, attrs)
(8)                     >>> G.nodes[0]["attr1"]
(8)                     20
(8)                     >>> G.nodes[0]["attr2"]
(8)                     'nothing'
```

```
(8)                 >>> G.nodes[1]["attr2"]
(8)                 3
(8)                 >>> G.nodes[2]
(8)                 {}
(4)             Note that if the dictionary contains nodes that are not in `G`, the
(4)             values are silently ignored::
(8)                 >>> G = nx.Graph()
(8)                 >>> G.add_node(0)
(8)                 >>> nx.set_node_attributes(G, {0: "red", 1: "blue"}, name="color")
(8)                 >>> G.nodes[0]["color"]
(8)                 'red'
(8)                 >>> 1 in G.nodes
(8)                 False
(4)             """
(4)             if name is not None:  # `values` must not be a dict of dict
(8)                 try:  # `values` is a dict
(12)                    for n, v in values.items():
(16)                        try:
(20)                            G.nodes[n][name] = values[n]
(16)                        except KeyError:
(20)                            pass
(8)                 except AttributeError:  # `values` is a constant
(12)                    for n in G:
(16)                        G.nodes[n][name] = values
(4)             else:  # `values` must be dict of dict
(8)                 for n, d in values.items():
(12)                    try:
(16)                        G.nodes[n].update(d)
(12)                    except KeyError:
(16)                        pass
(4)             nx._clear_cache(G)
(0)         def get_node_attributes(G, name, default=None):
(4)             """Get node attributes from graph
(4)             Parameters
(4)             ----------
(4)             G : NetworkX Graph
(4)             name : string
(7)                Attribute name
(4)             default: object (default=None)
(7)                Default value of the node attribute if there is no value set for that
(7)                node in graph. If `None` then nodes without this attribute are not
(7)                included in the returned dict.
(4)             Returns
(4)             -------
(4)             Dictionary of attributes keyed by node.
(4)             Examples
(4)             --------
(4)             >>> G = nx.Graph()
(4)             >>> G.add_nodes_from([1, 2, 3], color="red")
(4)             >>> color = nx.get_node_attributes(G, "color")
(4)             >>> color[1]
(4)             'red'
(4)             >>> G.add_node(4)
(4)             >>> color = nx.get_node_attributes(G, "color", default="yellow")
(4)             >>> color[4]
(4)             'yellow'
(4)             """
(4)             if default is not None:
(8)                 return {n: d.get(name, default) for n, d in G.nodes.items()}
(4)             return {n: d[name] for n, d in G.nodes.items() if name in d}
(0)         def set_edge_attributes(G, values, name=None):
(4)             """Sets edge attributes from a given value or dictionary of values.
(4)             .. Warning:: The call order of arguments `values` and `name`
(8)                 switched between v1.x & v2.x.
(4)             Parameters
(4)             ----------
(4)             G : NetworkX Graph
(4)             values : scalar value, dict-like
(8)                 What the edge attribute should be set to.  If `values` is
```

```
(8)                 not a dictionary, then it is treated as a single attribute value
(8)                 that is then applied to every edge in `G`.  This means that if
(8)                 you provide a mutable object, like a list, updates to that object
(8)                 will be reflected in the edge attribute for each edge.  The attribute
(8)                 name will be `name`.
(8)                 If `values` is a dict or a dict of dict, it should be keyed
(8)                 by edge tuple to either an attribute value or a dict of attribute
(8)                 key/value pairs used to update the edge's attributes.
(8)                 For multigraphs, the edge tuples must be of the form ``(u, v, key)``,
(8)                 where `u` and `v` are nodes and `key` is the edge key.
(8)                 For non-multigraphs, the keys must be tuples of the form ``(u, v)``.
(4)             name : string (optional, default=None)
(8)                 Name of the edge attribute to set if values is a scalar.
(4)             Examples
(4)             --------
(4)             After computing some property of the edges of a graph, you may want
(4)             to assign a edge attribute to store the value of that property for
(4)             each edge::
(8)                 >>> G = nx.path_graph(3)
(8)                 >>> bb = nx.edge_betweenness_centrality(G, normalized=False)
(8)                 >>> nx.set_edge_attributes(G, bb, "betweenness")
(8)                 >>> G.edges[1, 2]["betweenness"]
(8)                 2.0
(4)             If you provide a list as the second argument, updates to the list
(4)             will be reflected in the edge attribute for each edge::
(8)                 >>> labels = []
(8)                 >>> nx.set_edge_attributes(G, labels, "labels")
(8)                 >>> labels.append("foo")
(8)                 >>> G.edges[0, 1]["labels"]
(8)                 ['foo']
(8)                 >>> G.edges[1, 2]["labels"]
(8)                 ['foo']
(4)             If you provide a dictionary of dictionaries as the second argument,
(4)             the entire dictionary will be used to update edge attributes::
(8)                 >>> G = nx.path_graph(3)
(8)                 >>> attrs = {(0, 1): {"attr1": 20, "attr2": "nothing"}, (1, 2):
{"attr2": 3}}
(8)                 >>> nx.set_edge_attributes(G, attrs)
(8)                 >>> G[0][1]["attr1"]
(8)                 20
(8)                 >>> G[0][1]["attr2"]
(8)                 'nothing'
(8)                 >>> G[1][2]["attr2"]
(8)                 3
(4)             The attributes of one Graph can be used to set those of another.
(8)                 >>> H = nx.path_graph(3)
(8)                 >>> nx.set_edge_attributes(H, G.edges)
(4)             Note that if the dict contains edges that are not in `G`, they are
(4)             silently ignored::
(8)                 >>> G = nx.Graph([(0, 1)])
(8)                 >>> nx.set_edge_attributes(G, {(1, 2): {"weight": 2.0}})
(8)                 >>> (1, 2) in G.edges()
(8)                 False
(4)             For multigraphs, the `values` dict is expected to be keyed by 3-tuples
(4)             including the edge key::
(8)                 >>> MG = nx.MultiGraph()
(8)                 >>> edges = [(0, 1), (0, 1)]
(8)                 >>> MG.add_edges_from(edges)  # Returns list of edge keys
(8)                 [0, 1]
(8)                 >>> attributes = {(0, 1, 0): {"cost": 21}, (0, 1, 1): {"cost": 7}}
(8)                 >>> nx.set_edge_attributes(MG, attributes)
(8)                 >>> MG[0][1][0]["cost"]
(8)                 21
(8)                 >>> MG[0][1][1]["cost"]
(8)                 7
(4)             If MultiGraph attributes are desired for a Graph, you must convert the 3-
tuple
(4)             multiedge to a 2-tuple edge and the last multiedge's attribute value will
(4)             overwrite the previous values. Continuing from the previous case we get::
```

```
(8)                     >>> H = nx.path_graph([0, 1, 2])
(8)                     >>> nx.set_edge_attributes(H, {(u, v): ed for u, v, ed in
MG.edges.data()})
(8)                     >>> nx.get_edge_attributes(H, "cost")
(8)                     {(0, 1): 7}
(4)                 """

72: (4)                 Examples
73: (4)                 --------
74: (4)                 Create an empty graph structure (a "null graph") with no nodes and
75: (4)                 no edges.
76: (4)                 >>> G = nx.Graph()
77: (4)                 G can be grown in several ways.
78: (4)                 **Nodes:**
79: (4)                 Add one node at a time:
80: (4)                 >>> G.add_node(1)
81: (4)                 Add the nodes from any container (a list, dict, set or
82: (4)                 even the lines from a file or the nodes from another graph).
83: (4)                 >>> G.add_nodes_from([2, 3])
84: (4)                 >>> G.add_nodes_from(range(100, 110))
85: (4)                 >>> H = nx.path_graph(10)
86: (4)                 >>> G.add_nodes_from(H)
87: (4)                 In addition to strings and integers any hashable Python object
88: (4)                 (except None) can represent a node, e.g. a customized node object,
89: (4)                 or even another Graph.
90: (4)                 >>> G.add_node(H)
91: (4)                 **Edges:**
92: (4)                 G can also be grown by adding edges.
93: (4)                 Add one edge,
94: (4)                 >>> G.add_edge(1, 2)
95: (4)                 a list of edges,
96: (4)                 >>> G.add_edges_from([(1, 2), (1, 3)])
97: (4)                 or a collection of edges,
98: (4)                 >>> G.add_edges_from(H.edges)
```

```
99: (4)                 If some edges connect nodes not yet in the graph, the nodes
100: (4)                are added automatically.  There are no errors when adding
101: (4)                nodes or edges that already exist.
102: (4)                **Attributes:**
103: (4)                Each graph, node, and edge can hold key/value attribute pairs
104: (4)                in an associated attribute dictionary (the keys must be hashable).
105: (4)                By default these are empty, but can be added or changed using
106: (4)                add_edge, add_node or direct manipulation of the attribute
107: (4)                dictionaries named graph, node and edge respectively.
108: (4)                >>> G = nx.Graph(day="Friday")
109: (4)                >>> G.graph
110: (4)                {'day': 'Friday'}
111: (4)                Add node attributes using add_node(), add_nodes_from() or G.nodes
112: (4)                >>> G.add_node(1, time="5pm")
113: (4)                >>> G.add_nodes_from([3], time="2pm")
114: (4)                >>> G.nodes[1]

117: (4)                >>> del G.nodes[1]["room"]  # remove attribute
118: (4)                >>> list(G.nodes(data=True))
119: (4)                [(1, {'time': '5pm'}), (3, {'time': '2pm'})]
120: (4)                Add edge attributes using add_edge(), add_edges_from(), subscript
121: (4)                notation, or G.edges.
122: (4)                >>> G.add_edge(1, 2, weight=4.7)
123: (4)                >>> G.add_edges_from([(3, 4), (4, 5)], color="red")
124: (4)                >>> G.add_edges_from([(1, 2, {"color": "blue"}), (2, 3, {"weight": 8})])
125: (4)                >>> G[1][2]["weight"] = 4.7
126: (4)                >>> G.edges[1, 2]["weight"] = 4
127: (4)                Warning: we protect the graph data structure by making `G.edges` a
128: (4)                read-only dict-like structure. However, you can assign to attributes
129: (4)                in e.g. `G.edges[1, 2]`. Thus, use 2 sets of brackets to add/change
130: (4)                data attributes: `G.edges[1, 2]['weight'] = 4`
131: (4)                (For multigraphs: `MG.edges[u, v, key][name] = value`).
132: (4)                **Shortcuts:**
133: (4)                Many common graph features allow python syntax to speed reporting.
134: (4)                >>> 1 in G  # check if node in graph
135: (4)                True
136: (4)                >>> [n for n in G if n < 3]  # iterate through nodes
137: (4)                [1, 2]
138: (4)                >>> len(G)  # number of nodes in graph
139: (4)                5
140: (4)                Often the best way to traverse all edges of a graph is via the neighbors.
141: (4)                The neighbors are reported as an adjacency-dict `G.adj` or `G.adjacency()`
142: (4)                >>> for n, nbrsdict in G.adjacency():
143: (4)                ...     for nbr, eattr in nbrsdict.items():
144: (4)                ...         if "weight" in eattr:
145: (4)                ...             # Do something useful with the edges
146: (4)                ...             pass
147: (4)                But the edges() method is often more convenient:
148: (4)                >>> for u, v, weight in G.edges.data("weight"):
149: (4)                ...     if weight is not None:
150: (4)                ...         # Do something useful with the edges
151: (4)                ...         pass
152: (4)                **Reporting:**
153: (4)                Simple graph information is obtained using object-attributes and methods.
154: (4)                Reporting typically provides views instead of containers to reduce memory
155: (4)                usage. The views update as the graph is updated similarly to dict-views.
156: (4)                The objects `nodes`, `edges` and `adj` provide access to data attributes
157: (4)                via lookup (e.g. `nodes[n]`, `edges[u, v]`, `adj[u][v]`) and iteration
158: (4)                (e.g. `nodes.items()`, `nodes.data('color')`,
159: (4)                `nodes.data('color', default='blue')` and similarly for `edges`)
160: (4)                Views exist for `nodes`, `edges`, `neighbors()`/`adj` and `degree`.
161: (4)                For details on these and other miscellaneous methods, see below.
162: (4)                **Subclasses (Advanced):**
163: (4)                The Graph class uses a dict-of-dict-of-dict data structure.
164: (4)                The outer dict (node_dict) holds adjacency information keyed by node.
165: (4)                The next dict (adjlist_dict) represents the adjacency information and
holds
166: (4)                edge data keyed by neighbor.  The inner dict (edge_attr_dict) represents
```

```
    the edge data and holds edge attribute values keyed by attribute names.
    Each of these three dicts can be replaced in a subclass by a user defined
    dict-like object. In general, the dict-like features should be
    maintained but extra features can be added. To replace one of the
    dicts create a new graph class by changing the class(!) variable
    holding the factory for that dict-like structure.
    node_dict_factory : function, (default: dict)
        Factory function to be used to create the dict containing node
        attributes, keyed by node id.
        It should require no arguments and return a dict-like object
    node_attr_dict_factory: function, (default: dict)
        Factory function to be used to create the node attribute
        dict which holds attribute values keyed by attribute name.
        It should require no arguments and return a dict-like object
    adjlist_outer_dict_factory : function, (default: dict)
        Factory function to be used to create the outer-most dict
        in the data structure that holds adjacency info keyed by node.
        It should require no arguments and return a dict-like object.
    adjlist_inner_dict_factory : function, (default: dict)
        Factory function to be used to create the adjacency list
        dict which holds edge data keyed by neighbor.
        It should require no arguments and return a dict-like object
    edge_attr_dict_factory : function, (default: dict)
        Factory function to be used to create the edge attribute
        dict which holds attribute values keyed by attribute name.
        It should require no arguments and return a dict-like object.
    graph_attr_dict_factory : function, (default: dict)
        Factory function to be used to create the graph attribute
        dict which holds attribute values keyed by attribute name.
        It should require no arguments and return a dict-like object.
    Typically, if your extension doesn't impact the data structure all
    methods will inherit without issue except: `to_directed/to_undirected`.
    By default these methods create a DiGraph/Graph class and you probably
    want them to create your extension of a DiGraph/Graph. To facilitate
    this we define two class variables that you can set in your subclass.
    to_directed_class : callable, (default: DiGraph or MultiDiGraph)
        Class to create a new graph structure in the `to_directed` method.
        If `None`, a NetworkX class (DiGraph or MultiDiGraph) is used.
    to_undirected_class : callable, (default: Graph or MultiGraph)
        Class to create a new graph structure in the `to_undirected` method.
        If `None`, a NetworkX class (Graph or MultiGraph) is used.
    **Subclassing Example**
    Create a low memory graph class that effectively disallows edge
    attributes by using a single attribute dict for all edges.
    This reduces the memory used, but you lose edge attributes.
    >>> class ThinGraph(nx.Graph):
    ...     all_edge_dict = {"weight": 1}
    ...
    ...     def single_edge_dict(self):
    ...         return self.all_edge_dict
    ...
    ...     edge_attr_dict_factory = single_edge_dict
    >>> G = ThinGraph()
    >>> G.add_edge(2, 1)
    >>> G[2][1]
    {'weight': 1}
    >>> G.add_edge(2, 2)
    >>> G[2][1] is G[2][2]
    True
    """
    _adj = _CachedPropertyResetterAdj()

        --------
        add_node
        Notes
        -----
        When adding nodes from an iterator over the graph you are changing,
        a `RuntimeError` can be raised with message:
        `RuntimeError: dictionary changed size during iteration`. This
        happens when the graph's underlying dictionary is modified during
        iteration. To avoid this error, evaluate the iterator into a separate
        object, e.g. by using `list(iterator_of_nodes)`, and pass this
        object to `G.add_nodes_from`.
        Examples
        --------
        >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> G.add_nodes_from("Hello")
        >>> K3 = nx.Graph([(0, 1), (1, 2), (2, 0)])
        >>> G.add_nodes_from(K3)
        >>> sorted(G.nodes(), key=str)
        [0, 1, 2, 'H', 'e', 'l', 'o']
        Use keywords to update specific node attributes for every node.
        >>> G.add_nodes_from([1, 2], size=10)
        >>> G.add_nodes_from([3, 4], weight=0.4)
        Use (node, attrdict) tuples to update attributes for specific nodes.
        >>> G.add_nodes_from([(1, dict(size=11)), (2, {"color": "blue"})])
        >>> G.nodes[1]["size"]
        11
        >>> H = nx.Graph()
        >>> H.add_nodes_from(G.nodes(data=True))
        >>> H.nodes[1]["size"]
        11
        Evaluate an iterator over a graph if using it to modify the same graph
        >>> G = nx.Graph([(0, 1), (1, 2), (3, 4)])
        >>> # wrong way - will raise RuntimeError
        >>> # G.add_nodes_from(n + 1 for n in G.nodes)
        >>> # correct way
        >>> G.add_nodes_from(list(n + 1 for n in G.nodes))

585: (8)                    Can be used as `G.nodes` for data lookup and for set-like operations.
586: (8)                    Can also be used as `G.nodes(data='color', default=None)` to return a
587: (8)                    NodeDataView which reports specific node data but no set operations.
588: (8)                    It presents a dict-like interface as well with `G.nodes.items()`
589: (8)                    iterating over `(node, nodedata)` 2-tuples and `G.nodes[3]['foo']`
590: (8)                    providing the value of the `foo` attribute for node `3`. In addition,
591: (8)                    a view `G.nodes.data('foo')` provides a dict-like interface to the
592: (8)                    `foo` attribute of each node. `G.nodes.data('foo', default=1)`
593: (8)                    provides a default for nodes that do not have attribute `foo`.
594: (8)                    Parameters
595: (8)                    ----------
596: (8)                    data : string or bool, optional (default=False)
597: (12)                       The node attribute returned in 2-tuple (n, ddict[data]).
598: (12)                       If True, return entire node attribute dict as (n, ddict).
599: (12)                       If False, return just the nodes n.
600: (8)                    default : value, optional (default=None)
601: (12)                       Value used for nodes that don't have the requested attribute.
602: (12)                       Only relevant if data is not True or False.
603: (8)                    Returns
604: (8)                    -------
605: (8)                    NodeView
606: (12)                       Allows set-like operations over the nodes as well as node
607: (12)                       attribute dict lookup and calling to get a NodeDataView.
608: (12)                       A NodeDataView iterates over `(n, data)` and has no set
operations.
609: (12)                       A NodeView iterates over `n` and includes set operations.
610: (12)                       When called, if data is False, an iterator over nodes.
611: (12)                       Otherwise an iterator of 2-tuples (node, attribute value)
612: (12)                       where the attribute is specified in `data`.
613: (12)                       If data is True then the attribute becomes the
614: (12)                       entire data dictionary.
615: (8)                    Notes
616: (8)                    -----
617: (8)                    If your node data is not needed, it is simpler and equivalent
618: (8)                    to use the expression ``for n in G``, or ``list(G)``.
619: (8)                    Examples
620: (8)                    --------
621: (8)                    There are two simple ways of getting a list of all nodes in the graph:
622: (8)                    >>> G = nx.path_graph(3)
623: (8)                    >>> list(G.nodes)
624: (8)                    [0, 1, 2]
625: (8)                    >>> list(G)
626: (8)                    [0, 1, 2]

(4)                 def add_edge(self, u_of_edge, v_of_edge, **attr):
```

```
        """Add an edge between u and v.
        The nodes u and v will be automatically added if they are
        not already in the graph.
        Edge attributes can be specified with keywords or by directly
        accessing the edge's attribute dictionary. See examples below.
        Parameters
        ----------
        u_of_edge, v_of_edge : nodes
            Nodes can be, for example, strings or numbers.
            Nodes must be hashable (and not None) Python objects.
        attr : keyword arguments, optional
            Edge data (or labels or objects) can be assigned using
            keyword arguments.
        See Also
        --------
        add_edges_from : add a collection of edges
        Notes
        -----
        Adding an edge that already exists updates the edge data.
        Many NetworkX algorithms designed for weighted graphs use
        an edge attribute (by default `weight`) to hold a numerical value.
        Examples
        --------
        The following all add the edge e=(1, 2) to graph G:
        >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> e = (1, 2)
        >>> G.add_edge(1, 2)  # explicit two-node form
        >>> G.add_edge(*e)  # single edge as tuple of two nodes
        >>> G.add_edges_from([(1, 2)])  # add edges from iterable container
        Associate data to edges using keywords:
        >>> G.add_edge(1, 2, weight=3)
        >>> G.add_edge(1, 3, weight=7, capacity=15, length=342.7)
        For non-string attribute keys, use subscript notation.
        >>> G.add_edge(1, 2)
        >>> G[1][2].update({0: 5})
        >>> G.edges[1, 2].update({0: 5})
        """

        """Add all the edges in ebunch_to_add.
        Parameters
        ----------
        ebunch_to_add : container of edges
            Each edge given in the container will be added to the
            graph. The edges must be given as 2-tuples (u, v) or
            3-tuples (u, v, d) where d is a dictionary containing edge data.
        attr : keyword arguments, optional
            Edge data (or labels or objects) can be assigned using
            keyword arguments.
        See Also
        --------
        add_edge : add a single edge
        add_weighted_edges_from : convenient way to add weighted edges
        Notes
```

```
(8)                     -----
(8)                     Adding the same edge twice has no effect but any edge data
(8)                     will be updated when each duplicate edge is added.
(8)                     Edge attributes specified in an ebunch take precedence over
(8)                     attributes specified via keyword arguments.
(8)                     When adding edges from an iterator over the graph you are changing,
(8)                     a `RuntimeError` can be raised with message:
(8)                     `RuntimeError: dictionary changed size during iteration`. This
(8)                     happens when the graph's underlying dictionary is modified during
(8)                     iteration. To avoid this error, evaluate the iterator into a separate
(8)                     object, e.g. by using `list(iterator_of_edges)`, and pass this
(8)                     object to `G.add_edges_from`.
(8)                     Examples
(8)                     --------
(8)                     >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc

            if u in adj and v in adj[u]:
                del adj[u][v]
                if u != v:  # self loop needs only one entry removed
                    del adj[v][u]
        nx._clear_cache(self)
    def update(self, edges=None, nodes=None):
        """Update the graph using nodes/edges/graphs as input.
        Like dict.update, this method takes a graph as input, adding the
        graph's nodes and edges to this graph. It can also take two inputs:
        edges and nodes. Finally it can take either edges or nodes.
        To specify only nodes the keyword `nodes` must be used.
        The collections of edges and nodes are treated similarly to
        the add_edges_from/add_nodes_from methods. When iterated, they
        should yield 2-tuples (u, v) or 3-tuples (u, v, datadict).
        Parameters
        ----------
        edges : Graph object, collection of edges, or None
            The first parameter can be a graph or some edges. If it has
            attributes `nodes` and `edges`, then it is taken to be a
            Graph-like object and those attributes are used as collections
            of nodes and edges to be added to the graph.
            If the first parameter does not have those attributes, it is
            treated as a collection of edges and added to the graph.
            If the first argument is None, no edges are added.
        nodes : collection of nodes, or None
            The second parameter is treated as a collection of nodes
            to be added to the graph unless it is None.
            If `edges is None` and `nodes is None` an exception is raised.
            If the first parameter is a Graph, then `nodes` is ignored.
        Examples
        --------
        >>> G = nx.path_graph(5)
        >>> G.update(nx.complete_graph(range(4, 10)))
        >>> from itertools import combinations
        >>> edges = (
        ...     (u, v, {"power": u * v})
        ...     for u, v in combinations(range(10, 20), 2)
        ...     if u * v < 225
        ... )
        >>> nodes = [1000]  # for singleton, use a container
        >>> G.update(edges, nodes)
        Notes
        -----
        It you want to update the graph using an adjacency structure
        it is straightforward to obtain the edges/nodes from adjacency.
        The following examples provide common cases, your adjacency may
        be slightly different and require tweaks of these examples::
        >>> # dict-of-set/list/tuple
        >>> adj = {1: {2, 3}, 2: {1, 3}, 3: {1, 2}}
        >>> e = [(u, v) for u, nbrs in adj.items() for v in nbrs]
        >>> G.update(edges=e, nodes=adj)
        >>> DG = nx.DiGraph()
        >>> # dict-of-dict-of-attribute
        >>> adj = {1: {2: 1.3, 3: 0.7}, 2: {1: 1.4}, 3: {1: 0.7}}
```

```
985: (8)                    >>> e = [(u, v, {"weight": d}) for u, nbrs in adj.items() for v, d in
nbrs.items()]
986: (8)                    >>> DG.update(edges=e, nodes=adj)
987: (8)                    >>> # dict-of-dict-of-dict

(8)                 Notes
(8)                 -----
(8)                 Alternate ways to access the neighbors are ``G.adj[n]`` or ``G[n]``:
(8)                 >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
(8)                 >>> G.add_edge("a", "b", weight=7)
(8)                 >>> G["a"]
(8)                 AtlasView({'b': {'weight': 7}})
(8)                 >>> G = nx.path_graph(4)
(8)                 >>> [n for n in G[0]]
(8)                 [1]
(8)                 """
(8)                 try:
(12)                    return iter(self._adj[n])
(8)                 except KeyError as err:
(12)                    raise NetworkXError(f"The node {n} is not in the graph.") from err
(4)             @cached_property
(4)             def edges(self):
(8)                 """An EdgeView of the Graph as G.edges or G.edges().
(8)                 edges(self, nbunch=None, data=False, default=None)
(8)                 The EdgeView provides set-like operations on the edge-tuples
(8)                 as well as edge attribute lookup. When called, it also provides
(8)                 an EdgeDataView object which allows control of access to edge
(8)                 attributes (but does not provide set-like operations).
(8)                 Hence, `G.edges[u, v]['color']` provides the value of the color
(8)                 attribute for edge `(u, v)` while
(8)                 `for (u, v, c) in G.edges.data('color', default='red'):`
(8)                 iterates through all the edges yielding the color attribute
(8)                 with default `'red'` if no color attribute exists.
(8)                 Parameters
(8)                 ----------
(8)                 nbunch : single node, container, or all nodes (default= all nodes)
(12)                    The view will only report edges from these nodes.
(8)                 data : string or bool, optional (default=False)
(12)                    The edge attribute returned in 3-tuple (u, v, ddict[data]).
(12)                    If True, return edge attribute dict in 3-tuple (u, v, ddict).
(12)                    If False, return 2-tuple (u, v).
(8)                 default : value, optional (default=None)

```

```
            Only relevant if data is not True or False.
        Returns
        -------
        edges : EdgeView
            A view of edge attributes, usually it iterates over (u, v)
            or (u, v, d) tuples of edges, but can also be used for
            attribute lookup as `edges[u, v]['foo']`.
        Notes
        -----
        Nodes in nbunch that are not in the graph will be (quietly) ignored.
        For directed graphs this returns the out-edges.
        Examples
        --------
        >>> G = nx.path_graph(3)  # or MultiGraph, etc
        >>> G.add_edge(2, 3, weight=5)
        >>> [e for e in G.edges]
        [(0, 1), (1, 2), (2, 3)]
        >>> G.edges.data()  # default data is {} (empty dict)

        This is identical to `G[u][v]` except the default is returned
        instead of an exception if the edge doesn't exist.
        Parameters
        ----------
        u, v : nodes
        default:  any Python object (default=None)
            Value to return if the edge (u, v) is not found.
        Returns
        -------
        edge_dict : dictionary
            The edge attribute dictionary.
        Examples
        --------
        >>> G = nx.path_graph(4)  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> G[0][1]
        {}
        Warning: Assigning to `G[u][v]` is not permitted.
        But it is safe to assign attributes `G[u][v]['foo']`
        >>> G[0][1]["weight"] = 7
        >>> G[0][1]["weight"]
        7
        >>> G[1][0]["weight"]

(8)                 """Returns a copy of the graph.
(8)                 The copy method by default returns an independent shallow copy
(8)                 of the graph and attributes. That is, if an attribute is a
(8)                 container, that container is shared by the original an the copy.
(8)                 Use Python's `copy.deepcopy` for new containers.
(8)                 If `as_view` is True then a view is returned instead of a copy.
(8)                 Notes
(8)                 -----
(8)                 All copies reproduce the graph structure, but data attributes
(8)                 may be handled in different ways. There are four types of copies
(8)                 of a graph that people might want.
(8)                 Deepcopy -- A "deepcopy" copies the graph structure as well as
(8)                 all data attributes and any objects they might contain.
(8)                 The entire graph object is new so that changes in the copy
(8)                 do not affect the original object. (see Python's copy.deepcopy)
(8)                 Data Reference (Shallow) -- For a shallow copy the graph structure
(8)                 is copied but the edge, node and graph attribute dicts are
(8)                 references to those in the original graph. This saves
(8)                 time and memory but could cause confusion if you change an attribute
(8)                 in one graph and it changes the attribute in the other.
(8)                 NetworkX does not provide this level of shallow copy.
(8)                 Independent Shallow -- This copy creates new independent attribute
(8)                 dicts and then does a shallow copy of the attributes. That is, any
(8)                 attributes that are containers are shared between the new graph
(8)                 and the original. This is exactly what `dict.copy()` provides.
(8)                 You can obtain this style copy using:
(12)                    >>> G = nx.path_graph(5)
(12)                    >>> H = G.copy()
(12)                    >>> H = G.copy(as_view=False)
(12)                    >>> H = nx.Graph(G)
(12)                    >>> H = G.__class__(G)
(8)                 Fresh Data -- For fresh data, the graph structure is copied while
(8)                 new empty data attribute dicts are created. The resulting graph
(8)                 is independent of the original and it has no edge, node or graph
(8)                 attributes. Fresh copies are not enabled. Instead use:
(12)                    >>> H = G.__class__()
(12)                    >>> H.add_nodes_from(G)
(12)                    >>> H.add_edges_from(G.edges)
(8)                 View -- Inspired by dict-views, graph-views act like read-only
(8)                 versions of the original graph, providing a copy of the original
(8)                 structure without requiring any memory for copying the information.
(8)                 See the Python copy module for more information on shallow
(8)                 and deep copies, https://docs.python.org/3/library/copy.html.
(8)                 Parameters
(8)                 ----------
(8)                 as_view : bool, optional (default=False)
(12)                    If True, the returned graph-view provides a read-only view
(12)                    of the original graph without actually copying any data.
(8)                 Returns
(8)                 -------
(8)                 G : Graph
(12)                    A copy of the graph.
(8)                 See Also
(8)                 --------
(8)                 to_directed: return a directed copy of the graph.
```

```
(8)                 Examples
(8)                 --------
(8)                 >>> G = nx.path_graph(4)  # or DiGraph, MultiGraph, MultiDiGraph, etc
(8)                 >>> H = G.copy()
(8)                 """
(8)                 if as_view is True:
(12)                    return nx.graphviews.generic_graph_view(self)
(8)                 G = self.__class__()
(8)                 G.graph.update(self.graph)
(8)                 G.add_nodes_from((n, d.copy()) for n, d in self._node.items())
(8)                 G.add_edges_from(
(12)                    (u, v, datadict.copy())
(12)                    for u, nbrs in self._adj.items()
(12)                    for v, datadict in nbrs.items()
(8)                 )
(8)                 return G
(4)             def to_directed(self, as_view=False):
(8)                 """Returns a directed representation of the graph.
(8)                 Returns
(8)                 -------
(8)                 G : DiGraph
(12)                    A directed graph with the same name, same nodes, and with
(12)                    each edge (u, v, data) replaced by two directed edges
(12)                    (u, v, data) and (v, u, data).
(8)                 Notes
(8)                 -----
(8)                 This returns a "deepcopy" of the edge, node, and
(8)                 graph attributes which attempts to completely copy
(8)                 all of the data and references.
(8)                 This is in contrast to the similar D=DiGraph(G) which returns a
(8)                 shallow copy of the data.
(8)                 See the Python copy module for more information on shallow
(8)                 and deep copies, https://docs.python.org/3/library/copy.html.
(8)                 Warning: If you have subclassed Graph to use dict-like objects
(8)                 in the data structure, those changes do not transfer to the
(8)                 DiGraph created by this method.
(8)                 Examples
(8)                 --------
(8)                 >>> G = nx.Graph()  # or MultiGraph, etc
(8)                 >>> G.add_edge(0, 1)
(8)                 >>> H = G.to_directed()
(8)                 >>> list(H.edges)
(8)                 [(0, 1), (1, 0)]
(8)                 If already directed, return a (deep) copy
(8)                 >>> G = nx.DiGraph()  # or MultiDiGraph, etc
(8)                 >>> G.add_edge(0, 1)
(8)                 >>> H = G.to_directed()

(8)                 -----
(8)                 This returns a "deepcopy" of the edge, node, and
(8)                 graph attributes which attempts to completely copy
(8)                 all of the data and references.
(8)                 This is in contrast to the similar `G = nx.DiGraph(D)` which returns a
(8)                 shallow copy of the data.
(8)                 See the Python copy module for more information on shallow
(8)                 and deep copies, https://docs.python.org/3/library/copy.html.
(8)                 Warning: If you have subclassed DiGraph to use dict-like objects
(8)                 in the data structure, those changes do not transfer to the
(8)                 Graph created by this method.
(8)                 Examples
(8)                 --------
(8)                 >>> G = nx.path_graph(2)  # or MultiGraph, etc
(8)                 >>> H = G.to_directed()
(8)                 >>> list(H.edges)
(8)                 [(0, 1), (1, 0)]
(8)                 >>> G2 = H.to_undirected()
(8)                 >>> list(G2.edges)
(8)                 [(0, 1)]
(8)                 """
(8)                 graph_class = self.to_undirected_class()
(8)                 if as_view is True:
(12)                    return nx.graphviews.generic_graph_view(self, graph_class)
(8)                 G = graph_class()
(8)                 G.graph.update(deepcopy(self.graph))
(8)                 G.add_nodes_from((n, deepcopy(d)) for n, d in self._node.items())
(8)                 G.add_edges_from(
(12)                    (u, v, deepcopy(d))
(12)                    for u, nbrs in self._adj.items()
(12)                    for v, d in nbrs.items()
(8)                 )
(8)                 return G
(4)             def subgraph(self, nodes):
(8)                 """Returns a SubGraph view of the subgraph induced on `nodes`.
(8)                 The induced subgraph of the graph contains the nodes in `nodes`
(8)                 and the edges between those nodes.
(8)                 Parameters
(8)                 ----------
(8)                 nodes : list, iterable
(12)                    A container of nodes which will be iterated through once.
(8)                 Returns
(8)                 -------
(8)                 G : SubGraph View
(12)                    A subgraph view of the graph. The graph structure cannot be
(12)                    changed but node/edge attributes can and are shared with the
(12)                    original graph.
(8)                 Notes
(8)                 -----
(8)                 The graph, edge and node attributes are shared with the original
graph.
(8)                 Changes to the graph structure is ruled out by the view, but changes
(8)                 to attributes are reflected in the original graph.
(8)                 To create a subgraph with its own copy of the edge/node attributes
use:
(8)                 G.subgraph(nodes).copy()
(8)                 For an inplace reduction of a graph to a subgraph you can remove
nodes:
(8)                 G.remove_nodes_from([n for n in G if n not in set(nodes)])
(8)                 Subgraph views are sometimes NOT what you want. In most cases where
(8)                 you want to do more than simply look at the induced edges, it makes
(8)                 more sense to just create the subgraph as its own graph with code
```

```
like:
                    ::
                        SG = G.__class__()
                        SG.add_nodes_from((n, G.nodes[n]) for n in largest_wcc)
                        if SG.is_multigraph():
                            SG.add_edges_from(
                                (n, nbr, key, d)
                                for n, nbrs in G.adj.items()
                                if n in largest_wcc
                                for nbr, keydict in nbrs.items()
                                if nbr in largest_wcc
                                for key, d in keydict.items()
                            )
                        else:
                            SG.add_edges_from(
                                (n, nbr, d)
                                for n, nbrs in G.adj.items()

```
        """Returns the number of edges or total of all edge weights.
        Parameters
        ----------
        weight : string or None, optional (default=None)
            The edge attribute that holds the numerical value used
            as a weight. If None, then each edge has weight 1.
        Returns
        -------
        size : numeric
            The number of edges or
            (if weight keyword is provided) the total weight sum.
            If weight is None, returns an int. Otherwise a float
            (or more general numeric if the weights are more general).
        See Also
        --------
        number_of_edges
        Examples
        --------
        >>> G = nx.path_graph(4)  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> G.size()
        3
        >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> G.add_edge("a", "b", weight=2)
        >>> G.add_edge("b", "c", weight=4)
        >>> G.size()
        2
        >>> G.size(weight="weight")
        6.0
        """
        s = sum(d for v, d in self.degree(weight=weight))
        return s // 2 if weight is None else s / 2
    def number_of_edges(self, u=None, v=None):
        """Returns the number of edges between two nodes.
        Parameters
        ----------
        u, v : nodes, optional (default=all edges)
            If u and v are specified, return the number of edges between
            u and v. Otherwise return the total number of all edges.
        Returns
        -------
        nedges : int
            The number of edges in the graph.  If nodes `u` and `v` are
            specified return the number of edges between those nodes. If
            the graph is directed, this only returns the number of edges
            from `u` to `v`.
        See Also
        --------
        size
        Examples
        --------
        For undirected graphs, this method counts the total number of
        edges in the graph:
        >>> G = nx.path_graph(4)
        >>> G.number_of_edges()
        3
        If you specify two nodes, this counts the total number of edges
        joining the two nodes:
        >>> G.number_of_edges(0, 1)
        1
        For directed graphs, this method can count the total number of
        directed edges from `u` to `v`:
        >>> G = nx.DiGraph()
        >>> G.add_edge(0, 1)
        >>> G.add_edge(1, 0)
        >>> G.number_of_edges(0, 1)
        1
        """

File 394 - graphviews.py:

```
1: (0)              """View of Graphs as SubGraph, Reverse, Directed, Undirected.
2: (0)              In some algorithms it is convenient to temporarily morph
3: (0)              a graph to exclude some nodes or edges. It should be better
4: (0)              to do that via a view than to remove and then re-add.
5: (0)              In other algorithms it is convenient to temporarily morph
```

```
(0)             a graph to reverse directed edges, or treat a directed graph
(0)             as undirected, etc. This module provides those graph views.
(0)             The resulting views are essentially read-only graphs that
(0)             report data from the original graph object. We provide an
(0)             attribute G._graph which points to the underlying graph object.
(0)             Note: Since graphviews look like graphs, one can end up with
(0)             view-of-view-of-view chains. Be careful with chains because
(0)             they become very slow with about 15 nested views.
(0)             For the common simple case of node induced subgraphs created
(0)             from the graph class, we short-cut the chain by returning a
(0)             subgraph of the original graph directly rather than a subgraph
(0)             of a subgraph. We are careful not to disrupt any edge filter in
(0)             the middle subgraph. In general, determining how to short-cut
(0)             the chain is tricky and much harder with restricted_views than
(0)             with induced subgraphs.
(0)             Often it is easiest to use .copy() to avoid chains.
(0)             """

(0)             __all__ = ["generic_graph_view", "subgraph_view", "reverse_view"]
(0)             def generic_graph_view(G, create_using=None):
(4)                 """Returns a read-only view of `G`.
(4)                 The graph `G` and its attributes are not copied but viewed through the new
graph object
(4)                 of the same class as `G` (or of the class specified in `create_using`).
(4)                 Parameters
(4)                 ----------
(4)                 G : graph
(8)                     A directed/undirected graph/multigraph.
(4)                 create_using : NetworkX graph constructor, optional (default=None)
(7)                    Graph type to create. If graph instance, then cleared before populated.
(7)                    If `None`, then the appropriate Graph type is inferred from `G`.
(4)                 Returns
(4)                 -------
(4)                 newG : graph
(8)                     A view of the input graph `G` and its attributes as viewed through
(8)                     the `create_using` class.
(4)                 Raises
(4)                 ------
(4)                 NetworkXError
(8)                     If `G` is a multigraph (or multidigraph) but `create_using` is not, or
vice versa.
(4)                 Notes
(4)                 -----
(4)                 The returned graph view is read-only (cannot modify the graph).
(4)                 Yet the view reflects any changes in `G`. The intent is to mimic dict
views.
(4)                 Examples
(4)                 --------
(4)                 >>> G = nx.Graph()
(4)                 >>> G.add_edge(1, 2, weight=0.3)

(0)             @deprecate_positional_args(version="3.4")
(0)             def subgraph_view(G, *, filter_node=no_filter, filter_edge=no_filter):
(4)                 """View of `G` applying a filter on nodes and edges.
(4)                 `subgraph_view` provides a read-only view of the input graph that excludes
(4)                 nodes and edges based on the outcome of two filter functions `filter_node`
(4)                 and `filter_edge`.
(4)                 The `filter_node` function takes one argument --- the node --- and returns
(4)                 `True` if the node should be included in the subgraph, and `False` if it
(4)                 should not be included.
(4)                 The `filter_edge` function takes two (or three arguments if `G` is a
(4)                 multi-graph) --- the nodes describing an edge, plus the edge-key if
(4)                 parallel edges are possible --- and returns `True` if the edge should be
(4)                 included in the subgraph, and `False` if it should not be included.
(4)                 Both node and edge filter functions are called on graph elements as they
(4)                 are queried, meaning there is no up-front cost to creating the view.
(4)                 Parameters
(4)                 ----------
(4)                 G : networkx.Graph
(8)                     A directed/undirected graph/multigraph
(4)                 filter_node : callable, optional
(8)                     A function taking a node as input, which returns `True` if the node
(8)                     should appear in the view.
(4)                 filter_edge : callable, optional
(8)                     A function taking as input the two nodes describing an edge (plus the
(8)                     edge-key if `G` is a multi-graph), which returns `True` if the edge
(8)                     should appear in the view.
(4)                 Returns
(4)                 -------
(4)                 graph : networkx.Graph
(8)                     A read-only graph view of the input graph.
(4)                 Examples
(4)                 --------
(4)                 >>> G = nx.path_graph(6)
```

```
(4)                 Filter functions operate on the node, and return `True` if the node should
(4)                 appear in the view:
(4)                 >>> def filter_node(n1):
(4)                 ...     return n1 != 5
(4)                 >>> view = nx.subgraph_view(G, filter_node=filter_node)
(4)                 >>> view.nodes()
(4)                 NodeView((0, 1, 2, 3, 4))
(4)                 We can use a closure pattern to filter graph elements based on additional
(4)                 data --- for example, filtering on edge data attached to the graph:
(4)                 >>> G[3][4]["cross_me"] = False
(4)                 >>> def filter_edge(n1, n2):
(4)                 ...     return G[n1][n2].get("cross_me", True)
(4)                 >>> view = nx.subgraph_view(G, filter_edge=filter_edge)
(4)                 >>> view.edges()
(4)                 EdgeView([(0, 1), (1, 2), (2, 3), (4, 5)])
(4)                 >>> view = nx.subgraph_view(
(4)                 ...     G,
(4)                 ...     filter_node=filter_node,
(4)                 ...     filter_edge=filter_edge,
(4)                 ... )
(4)                 >>> view.nodes()
(4)                 NodeView((0, 1, 2, 3, 4))
(4)                 >>> view.edges()
(4)                 EdgeView([(0, 1), (1, 2), (2, 3)])
(4)                 """

57: (4)                 no edges.
58: (4)                 >>> G = nx.MultiDiGraph()
59: (4)                 G can be grown in several ways.
60: (4)                 **Nodes:**
61: (4)                 Add one node at a time:
62: (4)                 >>> G.add_node(1)
```

```
(4)                 Add the nodes from any container (a list, dict, set or
(4)                 even the lines from a file or the nodes from another graph).
(4)                 >>> G.add_nodes_from([2, 3])
(4)                 >>> G.add_nodes_from(range(100, 110))
(4)                 >>> H = nx.path_graph(10)
(4)                 >>> G.add_nodes_from(H)
(4)                 In addition to strings and integers any hashable Python object
(4)                 (except None) can represent a node, e.g. a customized node object,
(4)                 or even another Graph.
(4)                 >>> G.add_node(H)
(4)                 **Edges:**
(4)                 G can also be grown by adding edges.
(4)                 Add one edge,
(4)                 >>> key = G.add_edge(1, 2)
(4)                 a list of edges,
(4)                 >>> keys = G.add_edges_from([(1, 2), (1, 3)])
(4)                 or a collection of edges,
(4)                 >>> keys = G.add_edges_from(H.edges)
(4)                 If some edges connect nodes not yet in the graph, the nodes
(4)                 are added automatically.  If an edge already exists, an additional
(4)                 edge is created and stored using a key to identify the edge.
(4)                 By default the key is the lowest unused integer.
(4)                 >>> keys = G.add_edges_from([(4, 5, dict(route=282)), (4, 5,
dict(route=37))])
(4)                 >>> G[4]
(4)                 AdjacencyView({5: {0: {}, 1: {'route': 282}, 2: {'route': 37}}})
(4)                 **Attributes:**
(4)                 Each graph, node, and edge can hold key/value attribute pairs
(4)                 in an associated attribute dictionary (the keys must be hashable).
(4)                 By default these are empty, but can be added or changed using
(4)                 add_edge, add_node or direct manipulation of the attribute
(4)                 dictionaries named graph, node and edge respectively.
(4)                 >>> G = nx.MultiDiGraph(day="Friday")
(4)                 >>> G.graph
(4)                 {'day': 'Friday'}
(4)                 Add node attributes using add_node(), add_nodes_from() or G.nodes
(4)                 >>> G.add_node(1, time="5pm")
(4)                 >>> G.add_nodes_from([3], time="2pm")
(4)                 >>> G.nodes[1]
(4)                 {'time': '5pm'}
(4)                 >>> G.nodes[1]["room"] = 714
(4)                 >>> del G.nodes[1]["room"]  # remove attribute
(4)                 >>> list(G.nodes(data=True))
(4)                 [(1, {'time': '5pm'}), (3, {'time': '2pm'})]
(4)                 Add edge attributes using add_edge(), add_edges_from(), subscript
(4)                 notation, or G.edges.
(4)                 >>> key = G.add_edge(1, 2, weight=4.7)
(4)                 >>> keys = G.add_edges_from([(3, 4), (4, 5)], color="red")
(4)                 >>> keys = G.add_edges_from([(1, 2, {"color": "blue"}), (2, 3, {"weight":
8})])
(4)                 >>> G[1][2][0]["weight"] = 4.7
(4)                 >>> G.edges[1, 2, 0]["weight"] = 4
(4)                 Warning: we protect the graph data structure by making `G.edges[1,
(4)                 2, 0]` a read-only dict-like structure. However, you can assign to
(4)                 attributes in e.g. `G.edges[1, 2, 0]`. Thus, use 2 sets of brackets
(4)                 to add/change data attributes: `G.edges[1, 2, 0]['weight'] = 4`
(4)                 (for multigraphs the edge key is required: `MG.edges[u, v,
(4)                 key][name] = value`).
(4)                 **Shortcuts:**
(4)                 Many common graph features allow python syntax to speed reporting.
(4)                 >>> 1 in G  # check if node in graph
(4)                 True
(4)                 >>> [n for n in G if n < 3]  # iterate through nodes
(4)                 [1, 2]
(4)                 >>> len(G)  # number of nodes in graph
(4)                 5
(4)                 >>> G[1]  # adjacency dict-like view mapping neighbor -> edge key -> edge
attributes
(4)                 AdjacencyView({2: {0: {'weight': 4}, 1: {'color': 'blue'}}})
```

```
(4)                 Often the best way to traverse all edges of a graph is via the neighbors.
(4)                 The neighbors are available as an adjacency-view `G.adj` object or via
(4)                 the method `G.adjacency()`.
(4)                 >>> for n, nbrsdict in G.adjacency():
(4)                 ...     for nbr, keydict in nbrsdict.items():
(4)                 ...         for key, eattr in keydict.items():
(4)                 ...             if "weight" in eattr:
(4)                 ...                 # Do something useful with the edges
(4)                 ...                 pass
(4)                 But the edges() method is often more convenient:
(4)                 >>> for u, v, keys, weight in G.edges(data="weight", keys=True):
(4)                 ...     if weight is not None:
(4)                 ...         # Do something useful with the edges
(4)                 ...         pass
(4)                 **Reporting:**
(4)                 Simple graph information is obtained using methods and object-attributes.
(4)                 Reporting usually provides views instead of containers to reduce memory
(4)                 usage. The views update as the graph is updated similarly to dict-views.
(4)                 The objects `nodes`, `edges` and `adj` provide access to data attributes
(4)                 via lookup (e.g. `nodes[n]`, `edges[u, v, k]`, `adj[u][v]`) and iteration
(4)                 (e.g. `nodes.items()`, `nodes.data('color')`,
(4)                 `nodes.data('color', default='blue')` and similarly for `edges`)
(4)                 Views exist for `nodes`, `edges`, `neighbors()`/`adj` and `degree`.
(4)                 For details on these and other miscellaneous methods, see below.
(4)                 **Subclasses (Advanced):**
(4)                 The MultiDiGraph class uses a dict-of-dict-of-dict-of-dict structure.
(4)                 The outer dict (node_dict) holds adjacency information keyed by node.
(4)                 The next dict (adjlist_dict) represents the adjacency information
(4)                 and holds edge_key dicts keyed by neighbor. The edge_key dict holds
(4)                 each edge_attr dict keyed by edge key. The inner dict
(4)                 (edge_attr_dict) represents the edge data and holds edge attribute
(4)                 values keyed by attribute names.
(4)                 Each of these four dicts in the dict-of-dict-of-dict-of-dict
(4)                 structure can be replaced by a user defined dict-like object.
(4)                 In general, the dict-like features should be maintained but
(4)                 extra features can be added. To replace one of the dicts create
(4)                 a new graph class by changing the class(!) variable holding the
(4)                 factory for that dict-like structure. The variable names are
(4)                 node_dict_factory, node_attr_dict_factory, adjlist_inner_dict_factory,
(4)                 adjlist_outer_dict_factory, edge_key_dict_factory, edge_attr_dict_factory
(4)                 and graph_attr_dict_factory.
(4)                 node_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the dict containing node
(8)                     attributes, keyed by node id.
(8)                     It should require no arguments and return a dict-like object
(4)                 node_attr_dict_factory: function, (default: dict)
(8)                     Factory function to be used to create the node attribute
(8)                     dict which holds attribute values keyed by attribute name.
(8)                     It should require no arguments and return a dict-like object
(4)                 adjlist_outer_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the outer-most dict
(8)                     in the data structure that holds adjacency info keyed by node.
(8)                     It should require no arguments and return a dict-like object.
(4)                 adjlist_inner_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the adjacency list
(8)                     dict which holds multiedge key dicts keyed by neighbor.
(8)                     It should require no arguments and return a dict-like object.
(4)                 edge_key_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the edge key dict
(8)                     which holds edge data keyed by edge key.
(8)                     It should require no arguments and return a dict-like object.
(4)                 edge_attr_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the edge attribute
(8)                     dict which holds attribute values keyed by attribute name.
(8)                     It should require no arguments and return a dict-like object.
(4)                 graph_attr_dict_factory : function, (default: dict)
(8)                     Factory function to be used to create the graph attribute
(8)                     dict which holds attribute values keyed by attribute name.
(8)                     It should require no arguments and return a dict-like object.
```

```
    Typically, if your extension doesn't impact the data structure all
    methods will inherited without issue except: `to_directed/to_undirected`.
    By default these methods create a DiGraph/Graph class and you probably
    want them to create your extension of a DiGraph/Graph. To facilitate
    this we define two class variables that you can set in your subclass.
    to_directed_class : callable, (default: DiGraph or MultiDiGraph)
        Class to create a new graph structure in the `to_directed` method.
        If `None`, a NetworkX class (DiGraph or MultiDiGraph) is used.
    to_undirected_class : callable, (default: Graph or MultiGraph)
        Class to create a new graph structure in the `to_undirected` method.
        If `None`, a NetworkX class (Graph or MultiGraph) is used.
    **Subclassing Example**
    Create a low memory graph class that effectively disallows edge
    attributes by using a single attribute dict for all edges.
    This reduces the memory used, but you lose edge attributes.
    >>> class ThinGraph(nx.Graph):
    ...     all_edge_dict = {"weight": 1}
    ...
    ...     def single_edge_dict(self):
    ...         return self.all_edge_dict
    ...
    ...     edge_attr_dict_factory = single_edge_dict
    >>> G = ThinGraph()
    >>> G.add_edge(2, 1)
    >>> G[2][1]
    {'weight': 1}
    >>> G.add_edge(2, 2)
    >>> G[2][1] is G[2][2]
    True
    """
    edge_key_dict_factory = dict
    def __init__(self, incoming_graph_data=None, multigraph_input=None, **attr):
        """Initialize a graph with edges, name, or graph attributes.
        Parameters
        ----------
        incoming_graph_data : input graph
            Data to initialize graph.  If incoming_graph_data=None (default)
            an empty graph is created.  The data can be an edge list, or any
            NetworkX graph object.  If the corresponding optional Python
            packages are installed the data can also be a 2D NumPy array, a
            SciPy sparse array, or a PyGraphviz graph.
        multigraph_input : bool or None (default None)
            Note: Only used when `incoming_graph_data` is a dict.
            If True, `incoming_graph_data` is assumed to be a
            dict-of-dict-of-dict-of-dict structure keyed by
            node to neighbor to edge keys to edge data for multi-edges.
            A NetworkXError is raised if this is not the case.
            If False, :func:`to_networkx_graph` is used to try to determine
            the dict's graph data structure as either a dict-of-dict-of-dict
            keyed by node to neighbor to edge data, or a dict-of-iterable
            keyed by node to neighbors.
            If None, the treatment for True is tried, but if it fails,
            the treatment for False is tried.
        attr : keyword arguments, optional (default= no attributes)
            Attributes to add to graph as key=value pairs.
        See Also
        --------
        convert
        Examples
        --------
        >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> G = nx.Graph(name="my graph")
        >>> e = [(1, 2), (2, 3), (3, 4)]  # list of edges
        >>> G = nx.Graph(e)
        Arbitrary graph attribute pairs (key=value) may be assigned
        >>> G = nx.Graph(e, day="Friday")
        >>> G.graph
        {'day': 'Friday'}
```

```
266: (8)                    """

307: (8)                    For directed graphs, `G.succ` is identical to `G.adj`.
308: (8)                    """
309: (8)                    return MultiAdjacencyView(self._succ)
310: (4)                @cached_property
311: (4)                def pred(self):
312: (8)                    """Graph adjacency object holding the predecessors of each node.
313: (8)                    This object is a read-only dict-like structure with node keys
314: (8)                    and neighbor-dict values.  The neighbor-dict is keyed by neighbor
315: (8)                    to the edgekey-dict.  So `G.adj[3][2][0]['color'] = 'blue'` sets
316: (8)                    the color of the edge `(3, 2, 0)` to `"blue"`.
317: (8)                    Iterating over G.adj behaves like a dict. Useful idioms include
318: (8)                    `for nbr, datadict in G.adj[n].items():`.
319: (8)                    """
320: (8)                    return MultiAdjacencyView(self._pred)
321: (4)                def add_edge(self, u_for_edge, v_for_edge, key=None, **attr):
322: (8)                    """Add an edge between u and v.
323: (8)                    The nodes u and v will be automatically added if they are
324: (8)                    not already in the graph.
325: (8)                    Edge attributes can be specified with keywords or by directly
326: (8)                    accessing the edge's attribute dictionary. See examples below.
327: (8)                    Parameters
328: (8)                    ----------
329: (8)                    u_for_edge, v_for_edge : nodes
330: (12)                       Nodes can be, for example, strings or numbers.
331: (12)                       Nodes must be hashable (and not None) Python objects.
```

```
        key : hashable identifier, optional (default=lowest unused integer)
            Used to distinguish multiedges between a pair of nodes.
        attr : keyword arguments, optional
            Edge data (or labels or objects) can be assigned using
            keyword arguments.
        Returns
        -------
        The edge key assigned to the edge.
        See Also
        --------
        add_edges_from : add a collection of edges
        Notes
        -----
        To replace/update edge data, use the optional key argument
        to identify a unique edge.  Otherwise a new edge will be created.
        NetworkX algorithms designed for weighted graphs cannot use
        multigraphs directly because it is not clear how to handle
        multiedge weights.  Convert to Graph using edge attribute
        'weight' to enable weighted graph algorithms.
        Default keys are generated using the method `new_edge_key()`.
        This method can be overridden by subclassing the base class and
        providing a custom `new_edge_key()` method.
        Examples
        --------
        The following all add the edge e=(1, 2) to graph G:
        >>> G = nx.MultiDiGraph()
        >>> e = (1, 2)
        >>> key = G.add_edge(1, 2)  # explicit two-node form
        >>> G.add_edge(*e)  # single edge as tuple of two nodes
        1
        >>> G.add_edges_from([(1, 2)])  # add edges from iterable container
        [2]
        Associate data to edges using keywords:
        >>> key = G.add_edge(1, 2, weight=3)
        >>> key = G.add_edge(1, 2, key=0, weight=4)  # update data for key=0
        >>> key = G.add_edge(1, 3, weight=7, capacity=15, length=342.7)
        For non-string attribute keys, use subscript notation.
        >>> ekey = G.add_edge(1, 2)
        >>> G[1][2][0].update({0: 5})
        >>> G.edges[1, 2, 0].update({0: 5})
        """

(8)                 nx._clear_cache(self)
(4)             @cached_property
(4)             def edges(self):
(8)                 """An OutMultiEdgeView of the Graph as G.edges or G.edges().
(8)                 edges(self, nbunch=None, data=False, keys=False, default=None)
(8)                 The OutMultiEdgeView provides set-like operations on the edge-tuples
(8)                 as well as edge attribute lookup. When called, it also provides
```

```
(8)                     an EdgeDataView object which allows control of access to edge
(8)                     attributes (but does not provide set-like operations).
(8)                     Hence, ``G.edges[u, v, k]['color']`` provides the value of the color
(8)                     attribute for the edge from ``u`` to ``v`` with key ``k`` while
(8)                     ``for (u, v, k, c) in G.edges(data='color', default='red',
keys=True):``
(8)                     iterates through all the edges yielding the color attribute with
(8)                     default `'red'` if no color attribute exists.
(8)                     Edges are returned as tuples with optional data and keys
(8)                     in the order (node, neighbor, key, data). If ``keys=True`` is not
(8)                     provided, the tuples will just be (node, neighbor, data), but
(8)                     multiple tuples with the same node and neighbor will be
(8)                     generated when multiple edges between two nodes exist.
(8)                     Parameters
(8)                     ----------
(8)                     nbunch : single node, container, or all nodes (default= all nodes)
(12)                        The view will only report edges from these nodes.
(8)                     data : string or bool, optional (default=False)
(12)                        The edge attribute returned in 3-tuple (u, v, ddict[data]).
(12)                        If True, return edge attribute dict in 3-tuple (u, v, ddict).
(12)                        If False, return 2-tuple (u, v).
(8)                     keys : bool, optional (default=False)
(12)                        If True, return edge keys with each edge, creating (u, v, k,
(12)                        d) tuples when data is also requested (the default) and (u,
(12)                        v, k) tuples when data is not requested.
(8)                     default : value, optional (default=None)
(12)                        Value used for edges that don't have the requested attribute.
(12)                        Only relevant if data is not True or False.
(8)                     Returns
(8)                     -------
(8)                     edges : OutMultiEdgeView
(12)                        A view of edge attributes, usually it iterates over (u, v)
(12)                        (u, v, k) or (u, v, k, d) tuples of edges, but can also be
(12)                        used for attribute lookup as ``edges[u, v, k]['foo']``.
(8)                     Notes
(8)                     -----
(8)                     Nodes in nbunch that are not in the graph will be (quietly) ignored.
(8)                     For directed graphs this returns the out-edges.
(8)                     Examples
(8)                     --------
(8)                     >>> G = nx.MultiDiGraph()
(8)                     >>> nx.add_path(G, [0, 1, 2])

        The node degree is the number of edges adjacent to the node.
        The weighted node degree is the sum of the edge weights for
        edges incident to that node.
        This object provides an iterator for (node, degree) as well as
        lookup for the degree for a single node.
        Parameters
        ----------
        nbunch : single node, container, or all nodes (default= all nodes)
            The view will only report edges incident to these nodes.
        weight : string or None, optional (default=None)
           The name of an edge attribute that holds the numerical value used
           as a weight.  If None, then each edge has weight 1.
           The degree is the sum of the edge weights adjacent to the node.
        Returns
        -------
        DiMultiDegreeView or int
            If multiple nodes are requested (the default), returns a `DiMultiDegreeView`
            mapping nodes to their degree.
            If a single node is requested, returns the degree of the node as an integer.
        See Also

(8)                 """Returns an undirected representation of the digraph.
(8)                 Parameters
(8)                 ----------
(8)                 reciprocal : bool (optional)
(10)                  If True only keep edges that appear in both directions
(10)                  in the original digraph.
(8)                 as_view : bool (optional, default=False)
(10)                  If True return an undirected view of the original directed graph.
(8)                 Returns
(8)                 -------
(8)                 G : MultiGraph
(12)                    An undirected graph with the same name and nodes and
(12)                    with edge (u, v, data) if either (u, v, data) or (v, u, data)
(12)                    is in the digraph.  If both edges exist in digraph and
(12)                    their edge data is different, only one edge is created
(12)                    with an arbitrary choice of which edge data to use.
(12)                    You must check and correct for this manually if desired.
(8)                 See Also
(8)                 --------
(8)                 MultiGraph, copy, add_edge, add_edges_from
(8)                 Notes
(8)                 -----
(8)                 This returns a "deepcopy" of the edge, node, and
(8)                 graph attributes which attempts to completely copy
(8)                 all of the data and references.
(8)                 This is in contrast to the similar D=MultiDiGraph(G) which
(8)                 returns a shallow copy of the data.
(8)                 See the Python copy module for more information on shallow
(8)                 and deep copies, https://docs.python.org/3/library/copy.html.
(8)                 Warning: If you have subclassed MultiDiGraph to use dict-like
(8)                 objects in the data structure, those changes do not transfer
(8)                 to the MultiGraph created by this method.
(8)                 Examples
(8)                 --------
(8)                 >>> G = nx.path_graph(2)  # or MultiGraph, etc
(8)                 >>> H = G.to_directed()
(8)                 >>> list(H.edges)
(8)                 [(0, 1), (1, 0)]
(8)                 >>> G2 = H.to_undirected()
(8)                 >>> list(G2.edges)
(8)                 [(0, 1)]
(8)                 """

11: (4)                 """
12: (4)                 An undirected graph class that can store multiedges.
13: (4)                 Multiedges are multiple edges between two nodes.  Each edge
14: (4)                 can hold optional data or attributes.
15: (4)                 A MultiGraph holds undirected edges.  Self loops are allowed.
16: (4)                 Nodes can be arbitrary (hashable) Python objects with optional
17: (4)                 key/value attributes. By convention `None` is not used as a node.
18: (4)                 Edges are represented as links between nodes with optional
19: (4)                 key/value attributes, in a MultiGraph each edge has a key to
20: (4)                 distinguish between multiple edges that have the same source and
21: (4)                 destination nodes.
22: (4)                 Parameters
23: (4)                 ----------
24: (4)                 incoming_graph_data : input graph (optional, default: None)
```

```
(8)                     Data to initialize graph. If None (default) an empty
(8)                     graph is created.  The data can be any format that is supported
(8)                     by the to_networkx_graph() function, currently including edge list,
(8)                     dict of dicts, dict of lists, NetworkX graph, 2D NumPy array,
(8)                     SciPy sparse array, or PyGraphviz graph.
(4)                 multigraph_input : bool or None (default None)
(8)                     Note: Only used when `incoming_graph_data` is a dict.
(8)                     If True, `incoming_graph_data` is assumed to be a
(8)                     dict-of-dict-of-dict-of-dict structure keyed by
(8)                     node to neighbor to edge keys to edge data for multi-edges.
(8)                     A NetworkXError is raised if this is not the case.
(8)                     If False, :func:`to_networkx_graph` is used to try to determine
(8)                     the dict's graph data structure as either a dict-of-dict-of-dict
(8)                     keyed by node to neighbor to edge data, or a dict-of-iterable
(8)                     keyed by node to neighbors.
(8)                     If None, the treatment for True is tried, but if it fails,
(8)                     the treatment for False is tried.
(4)                 attr : keyword arguments, optional (default= no attributes)
(8)                     Attributes to add to graph as key=value pairs.

(4)                 Graph
(4)                 DiGraph
(4)                 MultiDiGraph
(4)                 Examples
(4)                 --------
(4)                 Create an empty graph structure (a "null graph") with no nodes and
(4)                 no edges.
(4)                 >>> G = nx.MultiGraph()
(4)                 G can be grown in several ways.
(4)                 **Nodes:**
(4)                 Add one node at a time:
(4)                 >>> G.add_node(1)
(4)                 Add the nodes from any container (a list, dict, set or
(4)                 even the lines from a file or the nodes from another graph).
(4)                 >>> G.add_nodes_from([2, 3])
(4)                 >>> G.add_nodes_from(range(100, 110))
(4)                 >>> H = nx.path_graph(10)
(4)                 >>> G.add_nodes_from(H)
(4)                 In addition to strings and integers any hashable Python object
(4)                 (except None) can represent a node, e.g. a customized node object,
(4)                 or even another Graph.
(4)                 >>> G.add_node(H)
(4)                 **Edges:**
(4)                 G can also be grown by adding edges.
(4)                 Add one edge,
(4)                 >>> key = G.add_edge(1, 2)
(4)                 a list of edges,
(4)                 >>> keys = G.add_edges_from([(1, 2), (1, 3)])
(4)                 or a collection of edges,
(4)                 >>> keys = G.add_edges_from(H.edges)
(4)                 If some edges connect nodes not yet in the graph, the nodes
(4)                 are added automatically.  If an edge already exists, an additional
(4)                 edge is created and stored using a key to identify the edge.
(4)                 By default the key is the lowest unused integer.
(4)                 >>> keys = G.add_edges_from([(4, 5, {"route": 28}), (4, 5, {"route":
37})])
(4)                 >>> G[4]
(4)                 AdjacencyView({3: {0: {}}, 5: {0: {}, 1: {'route': 28}, 2: {'route':
37}}})
(4)                 **Attributes:**
(4)                 Each graph, node, and edge can hold key/value attribute pairs
(4)                 in an associated attribute dictionary (the keys must be hashable).
(4)                 By default these are empty, but can be added or changed using
(4)                 add_edge, add_node or direct manipulation of the attribute
(4)                 dictionaries named graph, node and edge respectively.
(4)                 >>> G = nx.MultiGraph(day="Friday")
(4)                 >>> G.graph
(4)                 {'day': 'Friday'}
```

```
(4)                 Add node attributes using add_node(), add_nodes_from() or G.nodes
(4)                 >>> G.add_node(1, time="5pm")
(4)                 >>> G.add_nodes_from([3], time="2pm")
(4)                 >>> G.nodes[1]
(4)                 {'time': '5pm'}
(4)                 >>> G.nodes[1]["room"] = 714
(4)                 >>> del G.nodes[1]["room"]  # remove attribute
(4)                 >>> list(G.nodes(data=True))
(4)                 [(1, {'time': '5pm'}), (3, {'time': '2pm'})]
(4)                 Add edge attributes using add_edge(), add_edges_from(), subscript
(4)                 notation, or G.edges.
(4)                 >>> key = G.add_edge(1, 2, weight=4.7)
(4)                 >>> keys = G.add_edges_from([(3, 4), (4, 5)], color="red")
(4)                 >>> keys = G.add_edges_from([(1, 2, {"color": "blue"}), (2, 3, {"weight":
8})])
(4)                 >>> G[1][2][0]["weight"] = 4.7
(4)                 >>> G.edges[1, 2, 0]["weight"] = 4
(4)                 Warning: we protect the graph data structure by making `G.edges[1,
(4)                 2, 0]` a read-only dict-like structure. However, you can assign to
(4)                 attributes in e.g. `G.edges[1, 2, 0]`. Thus, use 2 sets of brackets
(4)                 to add/change data attributes: `G.edges[1, 2, 0]['weight'] = 4`.
(4)                 **Shortcuts:**
(4)                 Many common graph features allow python syntax to speed reporting.
(4)                 >>> 1 in G  # check if node in graph
(4)                 True
(4)                 >>> [n for n in G if n < 3]  # iterate through nodes
(4)                 [1, 2]
(4)                 >>> len(G)  # number of nodes in graph
(4)                 5
(4)                 >>> G[1]  # adjacency dict-like view mapping neighbor -> edge key -> edge
attributes
(4)                 AdjacencyView({2: {0: {'weight': 4}, 1: {'color': 'blue'}}})
(4)                 Often the best way to traverse all edges of a graph is via the neighbors.
(4)                 The neighbors are reported as an adjacency-dict `G.adj` or
`G.adjacency()`.
(4)                 >>> for n, nbrsdict in G.adjacency():
(4)                 ...     for nbr, keydict in nbrsdict.items():
(4)                 ...         for key, eattr in keydict.items():
(4)                 ...             if "weight" in eattr:
(4)                 ...                 # Do something useful with the edges
(4)                 ...                 pass
(4)                 But the edges() method is often more convenient:
(4)                 >>> for u, v, keys, weight in G.edges(data="weight", keys=True):
(4)                 ...     if weight is not None:
(4)                 ...         # Do something useful with the edges
(4)                 ...         pass
(4)                 **Reporting:**
(4)                 Simple graph information is obtained using methods and object-attributes.
(4)                 Reporting usually provides views instead of containers to reduce memory
(4)                 usage. The views update as the graph is updated similarly to dict-views.
(4)                 The objects `nodes`, `edges` and `adj` provide access to data attributes
(4)                 via lookup (e.g. `nodes[n]`, `edges[u, v, k]`, `adj[u][v]`) and iteration
(4)                 (e.g. `nodes.items()`, `nodes.data('color')`,
(4)                 `nodes.data('color', default='blue')` and similarly for `edges`)
(4)                 Views exist for `nodes`, `edges`, `neighbors()`/`adj` and `degree`.
(4)                 For details on these and other miscellaneous methods, see below.
(4)                 **Subclasses (Advanced):**
(4)                 The MultiGraph class uses a dict-of-dict-of-dict-of-dict data structure.
(4)                 The outer dict (node_dict) holds adjacency information keyed by node.
(4)                 The next dict (adjlist_dict) represents the adjacency information
(4)                 and holds edge_key dicts keyed by neighbor. The edge_key dict holds
(4)                 each edge_attr dict keyed by edge key. The inner dict
(4)                 (edge_attr_dict) represents the edge data and holds edge attribute
(4)                 values keyed by attribute names.
(4)                 Each of these four dicts in the dict-of-dict-of-dict-of-dict
(4)                 structure can be replaced by a user defined dict-like object.
(4)                 In general, the dict-like features should be maintained but
(4)                 extra features can be added. To replace one of the dicts create
(4)                 a new graph class by changing the class(!) variable holding the
```

```
    factory for that dict-like structure. The variable names are
    node_dict_factory, node_attr_dict_factory, adjlist_inner_dict_factory,
    adjlist_outer_dict_factory, edge_key_dict_factory, edge_attr_dict_factory
    and graph_attr_dict_factory.
    node_dict_factory : function, (default: dict)
        Factory function to be used to create the dict containing node
        attributes, keyed by node id.
        It should require no arguments and return a dict-like object
    node_attr_dict_factory: function, (default: dict)
        Factory function to be used to create the node attribute
        dict which holds attribute values keyed by attribute name.
        It should require no arguments and return a dict-like object
    adjlist_outer_dict_factory : function, (default: dict)
        Factory function to be used to create the outer-most dict
        in the data structure that holds adjacency info keyed by node.
        It should require no arguments and return a dict-like object.
    adjlist_inner_dict_factory : function, (default: dict)
        Factory function to be used to create the adjacency list
        dict which holds multiedge key dicts keyed by neighbor.
        It should require no arguments and return a dict-like object.
    edge_key_dict_factory : function, (default: dict)
        Factory function to be used to create the edge key dict
        which holds edge data keyed by edge key.
        It should require no arguments and return a dict-like object.
    edge_attr_dict_factory : function, (default: dict)
        Factory function to be used to create the edge attribute
        dict which holds attribute values keyed by attribute name.
        It should require no arguments and return a dict-like object.
    graph_attr_dict_factory : function, (default: dict)
        Factory function to be used to create the graph attribute
        dict which holds attribute values keyed by attribute name.
        It should require no arguments and return a dict-like object.
    Typically, if your extension doesn't impact the data structure all
    methods will inherited without issue except: `to_directed/to_undirected`.
    By default these methods create a DiGraph/Graph class and you probably
    want them to create your extension of a DiGraph/Graph. To facilitate
    this we define two class variables that you can set in your subclass.
    to_directed_class : callable, (default: DiGraph or MultiDiGraph)
        Class to create a new graph structure in the `to_directed` method.
        If `None`, a NetworkX class (DiGraph or MultiDiGraph) is used.
    to_undirected_class : callable, (default: Graph or MultiGraph)
        Class to create a new graph structure in the `to_undirected` method.
        If `None`, a NetworkX class (Graph or MultiGraph) is used.
    **Subclassing Example**
    Create a low memory graph class that effectively disallows edge
    attributes by using a single attribute dict for all edges.
    This reduces the memory used, but you lose edge attributes.
    >>> class ThinGraph(nx.Graph):
    ...     all_edge_dict = {"weight": 1}
    ...
    ...     def single_edge_dict(self):
    ...         return self.all_edge_dict
    ...
    ...     edge_attr_dict_factory = single_edge_dict
    >>> G = ThinGraph()
    >>> G.add_edge(2, 1)
    >>> G[2][1]
    {'weight': 1}
    >>> G.add_edge(2, 2)
    >>> G[2][1] is G[2][2]
    True
    """
    edge_key_dict_factory = dict
    def to_directed_class(self):
        """Returns the class to use for empty directed copies.
        If you subclass the base classes, use this to designate
        what directed class to use for `to_directed()` copies.
        """
        return nx.MultiDiGraph
```

```
    def to_undirected_class(self):
        """Returns the class to use for empty undirected copies.
        If you subclass the base classes, use this to designate
        what directed class to use for `to_directed()` copies.
        """
        return MultiGraph
    def __init__(self, incoming_graph_data=None, multigraph_input=None, **attr):
        """Initialize a graph with edges, name, or graph attributes.
        Parameters
        ----------
        incoming_graph_data : input graph
            Data to initialize graph.  If incoming_graph_data=None (default)
            an empty graph is created.  The data can be an edge list, or any
            NetworkX graph object.  If the corresponding optional Python
            packages are installed the data can also be a 2D NumPy array, a
            SciPy sparse array, or a PyGraphviz graph.
        multigraph_input : bool or None (default None)
            Note: Only used when `incoming_graph_data` is a dict.
            If True, `incoming_graph_data` is assumed to be a
            dict-of-dict-of-dict-of-dict structure keyed by
            node to neighbor to edge keys to edge data for multi-edges.
            A NetworkXError is raised if this is not the case.
            If False, :func:`to_networkx_graph` is used to try to determine
            the dict's graph data structure as either a dict-of-dict-of-dict
            keyed by node to neighbor to edge data, or a dict-of-iterable
            keyed by node to neighbors.
            If None, the treatment for True is tried, but if it fails,
            the treatment for False is tried.
        attr : keyword arguments, optional (default= no attributes)
            Attributes to add to graph as key=value pairs.
        See Also
        --------
        convert
        Examples
        --------
        >>> G = nx.MultiGraph()
        >>> G = nx.MultiGraph(name="my graph")
        >>> e = [(1, 2), (1, 2), (2, 3), (3, 4)]  # list of edges
        >>> G = nx.MultiGraph(e)
        Arbitrary graph attribute pairs (key=value) may be assigned
        >>> G = nx.MultiGraph(e, day="Friday")
        >>> G.graph
        {'day': 'Friday'}
        """
        if isinstance(incoming_graph_data, dict) and multigraph_input is not False:
            Graph.__init__(self)
            try:
                convert.from_dict_of_dicts(
                    incoming_graph_data, create_using=self, multigraph_input=True
                )
                self.graph.update(attr)
            except Exception as err:
                if multigraph_input is True:
                    raise nx.NetworkXError(
                        f"converting multigraph_input raised:\n{type(err)}: {err}"
                    )
                Graph.__init__(self, incoming_graph_data, **attr)
        else:
            Graph.__init__(self, incoming_graph_data, **attr)
    @cached_property
    def adj(self):
        """Graph adjacency object holding the neighbors of each node.
        This object is a read-only dict-like structure with node keys
        and neighbor-dict values.  The neighbor-dict is keyed by neighbor
        to the edgekey-data-dict.  So `G.adj[3][2][0]['color'] = 'blue'` sets
```

```
(8)                 the color of the edge `(3, 2, 0)` to `"blue"`.
(8)                 Iterating over G.adj behaves like a dict. Useful idioms include
(8)                 `for nbr, edgesdict in G.adj[n].items():`.
(8)                 The neighbor information is also provided by subscripting the graph.
(8)                 Examples
(8)                 --------
(8)                 >>> e = [(1, 2), (1, 2), (1, 3), (3, 4)]  # list of edges
(8)                 >>> G = nx.MultiGraph(e)
(8)                 >>> G.edges[1, 2, 0]["weight"] = 3
(8)                 >>> result = set()
(8)                 >>> for edgekey, data in G[1][2].items():
(8)                 ...     result.add(data.get("weight", 1))
(8)                 >>> result
(8)                 {1, 3}
(8)                 For directed graphs, `G.adj` holds outgoing (successor) info.
(8)                 """
(8)                 return MultiAdjacencyView(self._adj)
(4)             def new_edge_key(self, u, v):
(8)                 """Returns an unused key for edges between nodes `u` and `v`.
(8)                 The nodes `u` and `v` do not need to be already in the graph.
(8)                 Notes
(8)                 -----
(8)                 In the standard MultiGraph class the new key is the number of existing
(8)                 edges between `u` and `v` (increased if necessary to ensure unused).
(8)                 The first edge will have key 0, then 1, etc. If an edge is removed
(8)                 further new_edge_keys may not be in this order.
(8)                 Parameters
(8)                 ----------
(8)                 u, v : nodes
(8)                 Returns
(8)                 -------
(8)                 key : int
(8)                 """
(8)                 try:
(12)                    keydict = self._adj[u][v]
(8)                 except KeyError:
(12)                    return 0
(8)                 key = len(keydict)
(8)                 while key in keydict:
(12)                    key += 1
(8)                 return key
(4)             def add_edge(self, u_for_edge, v_for_edge, key=None, **attr):
(8)                 """Add an edge between u and v.
(8)                 The nodes u and v will be automatically added if they are
(8)                 not already in the graph.
(8)                 Edge attributes can be specified with keywords or by directly
(8)                 accessing the edge's attribute dictionary. See examples below.
(8)                 Parameters
(8)                 ----------
(8)                 u_for_edge, v_for_edge : nodes
(12)                    Nodes can be, for example, strings or numbers.
(12)                    Nodes must be hashable (and not None) Python objects.
(8)                 key : hashable identifier, optional (default=lowest unused integer)
(12)                    Used to distinguish multiedges between a pair of nodes.
(8)                 attr : keyword arguments, optional
(12)                    Edge data (or labels or objects) can be assigned using
(12)                    keyword arguments.
(8)                 Returns
(8)                 -------
(8)                 The edge key assigned to the edge.
(8)                 See Also
(8)                 --------
(8)                 add_edges_from : add a collection of edges
(8)                 Notes
(8)                 -----
(8)                 To replace/update edge data, use the optional key argument
(8)                 to identify a unique edge.  Otherwise a new edge will be created.
(8)                 NetworkX algorithms designed for weighted graphs cannot use
(8)                 multigraphs directly because it is not clear how to handle
```

```
(8)                     multiedge weights.  Convert to Graph using edge attribute
(8)                     'weight' to enable weighted graph algorithms.
(8)                     Default keys are generated using the method `new_edge_key()`.
(8)                     This method can be overridden by subclassing the base class and
(8)                     providing a custom `new_edge_key()` method.
(8)                     Examples
(8)                     --------
(8)                     The following each add an additional edge e=(1, 2) to graph G:
(8)                     >>> G = nx.MultiGraph()
(8)                     >>> e = (1, 2)
(8)                     >>> ekey = G.add_edge(1, 2)  # explicit two-node form
(8)                     >>> G.add_edge(*e)  # single edge as tuple of two nodes
(8)                     1
(8)                     >>> G.add_edges_from([(1, 2)])  # add edges from iterable container
(8)                     [2]
(8)                     Associate data to edges using keywords:
(8)                     >>> ekey = G.add_edge(1, 2, weight=3)
(8)                     >>> ekey = G.add_edge(1, 2, key=0, weight=4)  # update data for key=0
(8)                     >>> ekey = G.add_edge(1, 3, weight=7, capacity=15, length=342.7)
(8)                     For non-string attribute keys, use subscript notation.
(8)                     >>> ekey = G.add_edge(1, 2)
(8)                     >>> G[1][2][0].update({0: 5})
(8)                     >>> G.edges[1, 2, 0].update({0: 5})
(8)                     """
(8)                     u, v = u_for_edge, v_for_edge
(8)                     if u not in self._adj:

(8)                     Parameters
(8)                     ----------
(8)                     ebunch_to_add : container of edges
(12)                        Each edge given in the container will be added to the
(12)                        graph. The edges can be:
(16)                            - 2-tuples (u, v) or
(16)                            - 3-tuples (u, v, d) for an edge data dict d, or
(16)                            - 3-tuples (u, v, k) for not iterable key k, or
(16)                            - 4-tuples (u, v, k, d) for an edge with data and key k
(8)                     attr : keyword arguments, optional
(12)                        Edge data (or labels or objects) can be assigned using
(12)                        keyword arguments.
(8)                     Returns
(8)                     -------
(8)                     A list of edge keys assigned to the edges in `ebunch`.
(8)                     See Also
```

```
        --------
        add_edge : add a single edge
        add_weighted_edges_from : convenient way to add weighted edges
        Notes
        -----
        Adding the same edge twice has no effect but any edge data
        will be updated when each duplicate edge is added.
        Edge attributes specified in an ebunch take precedence over
        attributes specified via keyword arguments.
        Default keys are generated using the method ``new_edge_key()``.
        This method can be overridden by subclassing the base class and
        providing a custom ``new_edge_key()`` method.
        When adding edges from an iterator over the graph you are changing,
        a `RuntimeError` can be raised with message:
        `RuntimeError: dictionary changed size during iteration`. This
        happens when the graph's underlying dictionary is modified during
        iteration. To avoid this error, evaluate the iterator into a separate
        object, e.g. by using `list(iterator_of_edges)`, and pass this
        object to `G.add_edges_from`.
        Examples
        --------
        >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
        >>> G.add_edges_from([(0, 1), (1, 2)])  # using a list of edge tuples
        >>> e = zip(range(0, 3), range(1, 4))
        >>> G.add_edges_from(e)  # Add the path graph 0-1-2-3
        Associate data to edges
        >>> G.add_edges_from([(1, 2), (2, 3)], weight=3)
        >>> G.add_edges_from([(3, 4), (1, 4)], label="WN2898")
        Evaluate an iterator over a graph if using it to modify the same graph
        >>> G = nx.MultiGraph([(1, 2), (2, 3), (3, 4)])
        >>> # Grow graph by one new node, adding edges to all existing nodes.
        >>> # wrong way - will raise RuntimeError
        >>> # G.add_edges_from(((5, n) for n in G.nodes))
        >>> # right way - note that there will be no self-edge for node 5
        >>> assigned_keys = G.add_edges_from(list((5, n) for n in G.nodes))
        """

639: (8)                    >>> e = (0, 1, "a")
640: (8)                    >>> G.has_edge(*e)  # e is a 3-tuple (u, v, 'a')
641: (8)                    True
642: (8)                    The following syntax are equivalent:
643: (8)                    >>> G.has_edge(0, 1)
644: (8)                    True
645: (8)                    >>> 1 in G[0]  # though this gives :exc:`KeyError` if 0 not in G
646: (8)                    True
647: (8)                    >>> 0 in G[1]  # other order; also gives :exc:`KeyError` if 0 not in G
648: (8)                    True
649: (8)                    """
650: (8)                    try:
651: (12)                       if key is None:
652: (16)                           return v in self._adj[u]
653: (12)                       else:
654: (16)                           return key in self._adj[u][v]
655: (8)                    except KeyError:
656: (12)                       return False
657: (4)                @cached_property
658: (4)                def edges(self):
659: (8)                    """Returns an iterator over the edges.
660: (8)                    edges(self, nbunch=None, data=False, keys=False, default=None)
661: (8)                    The MultiEdgeView provides set-like operations on the edge-tuples
662: (8)                    as well as edge attribute lookup. When called, it also provides
663: (8)                    an EdgeDataView object which allows control of access to edge
664: (8)                    attributes (but does not provide set-like operations).
665: (8)                    Hence, ``G.edges[u, v, k]['color']`` provides the value of the color
666: (8)                    attribute for the edge from ``u`` to ``v`` with key ``k`` while
667: (8)                    ``for (u, v, k, c) in G.edges(data='color', keys=True,
default="red"):``
668: (8)                    iterates through all the edges yielding the color attribute with
669: (8)                    default `'red'` if no color attribute exists.
670: (8)                    Edges are returned as tuples with optional data and keys
671: (8)                    in the order (node, neighbor, key, data). If ``keys=True`` is not
672: (8)                    provided, the tuples will just be (node, neighbor, data), but
673: (8)                    multiple tuples with the same node and neighbor will be generated
674: (8)                    when multiple edges exist between two nodes.
675: (8)                    Parameters
676: (8)                    ----------
677: (8)                    nbunch : single node, container, or all nodes (default= all nodes)
678: (12)                       The view will only report edges from these nodes.
679: (8)                    data : string or bool, optional (default=False)
680: (12)                       The edge attribute returned in 3-tuple (u, v, ddict[data]).
681: (12)                       If True, return edge attribute dict in 3-tuple (u, v, ddict).
682: (12)                       If False, return 2-tuple (u, v).
683: (8)                    keys : bool, optional (default=False)
684: (12)                       If True, return edge keys with each edge, creating (u, v, k)
685: (12)                       tuples or (u, v, k, d) tuples if data is also requested.
686: (8)                    default : value, optional (default=None)
687: (12)                       Value used for edges that don't have the requested attribute.
688: (12)                       Only relevant if data is not True or False.
689: (8)                    Returns
690: (8)                    -------
691: (8)                    edges : MultiEdgeView
692: (12)                       A view of edge attributes, usually it iterates over (u, v)
693: (12)                       (u, v, k) or (u, v, k, d) tuples of edges, but can also be
694: (12)                       used for attribute lookup as ``edges[u, v, k]['foo']``.
695: (8)                    Notes
696: (8)                    -----
697: (8)                    Nodes in nbunch that are not in the graph will be (quietly) ignored.
698: (8)                    For directed graphs this returns the out-edges.
699: (8)                    Examples
700: (8)                    --------
701: (8)                    >>> G = nx.MultiGraph()

(8)                     """Returns the attribute dictionary associated with edge (u, v,
(8)                     key).
(8)                     If a key is not provided, returns a dictionary mapping edge keys
(8)                     to attribute dictionaries for each edge between u and v.
(8)                     This is identical to `G[u][v][key]` except the default is returned
(8)                     instead of an exception is the edge doesn't exist.
(8)                     Parameters
(8)                     ----------
(8)                     u, v : nodes
(8)                     default :  any Python object (default=None)
(12)                        Value to return if the specific edge (u, v, key) is not
(12)                        found, OR if there are no edges between u and v and no key
(12)                        is specified.
(8)                     key : hashable identifier, optional (default=None)
(12)                        Return data only for the edge with specified key, as an
(12)                        attribute dictionary (rather than a dictionary mapping keys
(12)                        to attribute dictionaries).
(8)                     Returns
(8)                     -------
(8)                     edge_dict : dictionary
(12)                        The edge attribute dictionary, OR a dictionary mapping edge
(12)                        keys to attribute dictionaries for each of those edges if no
(12)                        specific key is provided (even if there's only one edge
(12)                        between u and v).
(8)                     Examples
(8)                     --------
(8)                     >>> G = nx.MultiGraph()  # or MultiDiGraph
(8)                     >>> key = G.add_edge(0, 1, key="a", weight=7)
(8)                     >>> G[0][1]["a"]  # key='a'
(8)                     {'weight': 7}
(8)                     >>> G.edges[0, 1, "a"]  # key='a'
(8)                     {'weight': 7}
(8)                     Warning: we protect the graph data structure by making
(8)                     `G.edges` and `G[1][2]` read-only dict-like structures.
(8)                     However, you can assign values to attributes in e.g.
(8)                     `G.edges[1, 2, 'a']` or `G[1][2]['a']` using an additional
(8)                     bracket as shown next. You need to specify all edge info
(8)                     to assign to the edge data associated with an edge.
(8)                     >>> G[0][1]["a"]["weight"] = 10
(8)                     >>> G.edges[0, 1, "a"]["weight"] = 10
(8)                     >>> G[0][1]["a"]["weight"]

794: (8)                    The node degree is the number of edges adjacent to the node.
795: (8)                    The weighted node degree is the sum of the edge weights for
796: (8)                    edges incident to that node.
797: (8)                    This object provides an iterator for (node, degree) as well as
798: (8)                    lookup for the degree for a single node.
799: (8)                    Parameters
800: (8)                    ----------
801: (8)                    nbunch : single node, container, or all nodes (default= all nodes)
802: (12)                       The view will only report edges incident to these nodes.
803: (8)                    weight : string or None, optional (default=None)
804: (11)                      The name of an edge attribute that holds the numerical value used
805: (11)                      as a weight.  If None, then each edge has weight 1.
806: (11)                      The degree is the sum of the edge weights adjacent to the node.
807: (8)                    Returns
808: (8)                    -------
809: (8)                    MultiDegreeView or int
810: (12)                       If multiple nodes are requested (the default), returns a
`MultiDegreeView`
811: (12)                       mapping nodes to their degree.
812: (12)                       If a single node is requested, returns the degree of the node as
an integer.
813: (8)                    Examples
814: (8)                    --------
815: (8)                    >>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
816: (8)                    >>> nx.add_path(G, [0, 1, 2, 3])
817: (8)                    >>> G.degree(0)  # node 0 with degree 1
818: (8)                    1
819: (8)                    >>> list(G.degree([0, 1]))
820: (8)                    [(0, 1), (1, 2)]
821: (8)                    """
822: (8)                    return MultiDegreeView(self)
823: (4)                def is_multigraph(self):
824: (8)                    """Returns True if graph is a multigraph, False otherwise."""
825: (8)                    return True
826: (4)                def is_directed(self):
827: (8)                    """Returns True if graph is directed, False otherwise."""
828: (8)                    return False
829: (4)                def copy(self, as_view=False):
830: (8)                    """Returns a copy of the graph.
831: (8)                    The copy method by default returns an independent shallow copy
832: (8)                    of the graph and attributes. That is, if an attribute is a
833: (8)                    container, that container is shared by the original an the copy.
```

```
(8)                     Use Python's `copy.deepcopy` for new containers.
(8)                     If `as_view` is True then a view is returned instead of a copy.
(8)                     Notes
(8)                     -----
(8)                     All copies reproduce the graph structure, but data attributes
(8)                     may be handled in different ways. There are four types of copies
(8)                     of a graph that people might want.
(8)                     Deepcopy -- A "deepcopy" copies the graph structure as well as
(8)                     all data attributes and any objects they might contain.
(8)                     The entire graph object is new so that changes in the copy
(8)                     do not affect the original object. (see Python's copy.deepcopy)
(8)                     Data Reference (Shallow) -- For a shallow copy the graph structure
(8)                     is copied but the edge, node and graph attribute dicts are
(8)                     references to those in the original graph. This saves
(8)                     time and memory but could cause confusion if you change an attribute
(8)                     in one graph and it changes the attribute in the other.
(8)                     NetworkX does not provide this level of shallow copy.
(8)                     Independent Shallow -- This copy creates new independent attribute
(8)                     dicts and then does a shallow copy of the attributes. That is, any
(8)                     attributes that are containers are shared between the new graph
(8)                     and the original. This is exactly what `dict.copy()` provides.
(8)                     You can obtain this style copy using:
(12)                        >>> G = nx.path_graph(5)
(12)                        >>> H = G.copy()
(12)                        >>> H = G.copy(as_view=False)
(12)                        >>> H = nx.Graph(G)
(12)                        >>> H = G.__class__(G)
(8)                     Fresh Data -- For fresh data, the graph structure is copied while
(8)                     new empty data attribute dicts are created. The resulting graph
(8)                     is independent of the original and it has no edge, node or graph
(8)                     attributes. Fresh copies are not enabled. Instead use:
(12)                        >>> H = G.__class__()
(12)                        >>> H.add_nodes_from(G)
(12)                        >>> H.add_edges_from(G.edges)
(8)                     View -- Inspired by dict-views, graph-views act like read-only
(8)                     versions of the original graph, providing a copy of the original
(8)                     structure without requiring any memory for copying the information.
(8)                     See the Python copy module for more information on shallow
(8)                     and deep copies, https://docs.python.org/3/library/copy.html.
(8)                     Parameters
(8)                     ----------
(8)                     as_view : bool, optional (default=False)
(12)                        If True, the returned graph-view provides a read-only view
(12)                        of the original graph without actually copying any data.
(8)                     Returns
(8)                     -------
(8)                     G : Graph
(12)                        A copy of the graph.
(8)                     See Also
(8)                     --------
(8)                     to_directed: return a directed copy of the graph.
(8)                     Examples
(8)                     --------
(8)                     >>> G = nx.path_graph(4)  # or DiGraph, MultiGraph, MultiDiGraph, etc
(8)                     >>> H = G.copy()
(8)                     """
(8)                     if as_view is True:
(12)                        return nx.graphviews.generic_graph_view(self)
(8)                     G = self.__class__()
(8)                     G.graph.update(self.graph)
(8)                     G.add_nodes_from((n, d.copy()) for n, d in self._node.items())
(8)                     G.add_edges_from(
(12)                        (u, v, key, datadict.copy())
(12)                        for u, nbrs in self._adj.items()
(12)                        for v, keydict in nbrs.items()
(12)                        for key, datadict in keydict.items()
(8)                     )
(8)                     return G
(4)                 def to_directed(self, as_view=False):
```

```
(8)                 """Returns a directed representation of the graph.
(8)                 Returns
(8)                 -------
(8)                 G : MultiDiGraph
(12)                    A directed graph with the same name, same nodes, and with
(12)                    each edge (u, v, k, data) replaced by two directed edges
(12)                    (u, v, k, data) and (v, u, k, data).
(8)                 Notes
(8)                 -----
(8)                 This returns a "deepcopy" of the edge, node, and
(8)                 graph attributes which attempts to completely copy
(8)                 all of the data and references.
(8)                 This is in contrast to the similar D=MultiDiGraph(G) which
(8)                 returns a shallow copy of the data.
(8)                 See the Python copy module for more information on shallow
(8)                 and deep copies, https://docs.python.org/3/library/copy.html.
(8)                 Warning: If you have subclassed MultiGraph to use dict-like objects
(8)                 in the data structure, those changes do not transfer to the
(8)                 MultiDiGraph created by this method.
(8)                 Examples
(8)                 --------
(8)                 >>> G = nx.MultiGraph()
(8)                 >>> G.add_edge(0, 1)
(8)                 0
(8)                 >>> G.add_edge(0, 1)
(8)                 1
(8)                 >>> H = G.to_directed()

```

File 397 - reportviews.py:

```
1: (0)              """
2: (0)              View Classes provide node, edge and degree "views" of a graph.
3: (0)              Views for nodes, edges and degree are provided for all base graph classes.
4: (0)              A view means a read-only object that is quick to create, automatically
5: (0)              updated when the graph changes, and provides basic access like `n in V`,
6: (0)              `for n in V`, `V[n]` and sometimes set operations.
7: (0)              The views are read-only iterable containers that are updated as the
8: (0)              graph is updated. As with dicts, the graph should not be updated
9: (0)              while iterating through the view. Views can be iterated multiple times.
10: (0)             Edge and Node views also allow data attribute lookup.
11: (0)             The resulting attribute dict is writable as `G.edges[3, 4]['color']='red'`
12: (0)             Degree views allow lookup of degree values for single nodes.
13: (0)             Weighted degree is supported with the `weight` argument.
14: (0)             NodeView
15: (0)             ========
16: (4)                 `V = G.nodes` (or `V = G.nodes()`) allows `len(V)`, `n in V`, set
17: (4)                 operations e.g. "G.nodes & H.nodes", and `dd = G.nodes[n]`, where
18: (4)                 `dd` is the node data dict. Iteration is over the nodes by default.
19: (0)             NodeDataView
20: (0)             ============
21: (4)                 To iterate over (node, data) pairs, use arguments to `G.nodes()`
22: (4)                 to create a DataView e.g. `DV = G.nodes(data='color', default='red')`.
23: (4)                 The DataView iterates as `for n, color in DV` and allows
24: (4)                 `(n, 'red') in DV`. Using `DV = G.nodes(data=True)`, the DataViews
25: (4)                 use the full datadict in writeable form also allowing contain testing as
26: (4)                 `(n, {'color': 'red'}) in VD`. DataViews allow set operations when
27: (4)                 data attributes are hashable.
28: (0)             DegreeView
29: (0)             ==========
30: (4)                 `V = G.degree` allows iteration over (node, degree) pairs as well
31: (4)                 as lookup: `deg=V[n]`. There are many flavors of DegreeView
32: (4)                 for In/Out/Directed/Multi. For Directed Graphs, `G.degree`
33: (4)                 counts both in and out going edges. `G.out_degree` and
34: (4)                 `G.in_degree` count only specific directions.
35: (4)                 Weighted degree using edge data attributes is provide via
36: (4)                 `V = G.degree(weight='attr_name')` where any string with the
37: (4)                 attribute name can be used. `weight=None` is the default.
38: (4)                 No set operations are implemented for degrees, use NodeView.
39: (4)                 The argument `nbunch` restricts iteration to nodes in nbunch.
40: (4)                 The DegreeView can still lookup any node even if nbunch is specified.
41: (0)             EdgeView
42: (0)             ========
43: (4)                 `V = G.edges` or `V = G.edges()` allows iteration over edges as well as
44: (4)                 `e in V`, set operations and edge data lookup `dd = G.edges[2, 3]`.
45: (4)                 Iteration is over 2-tuples `(u, v)` for Graph/DiGraph. For multigraphs
46: (4)                 edges 3-tuples `(u, v, key)` are the default but 2-tuples can be obtained
47: (4)                 via `V = G.edges(keys=False)`.
48: (4)                 Set operations for directed graphs treat the edges as a set of 2-tuples.
49: (4)                 For undirected graphs, 2-tuples are not a unique representation of edges.
50: (4)                 So long as the set being compared to contains unique representations
51: (4)                 of its edges, the set operations will act as expected. If the other
52: (4)                 set contains both `(0, 1)` and `(1, 0)` however, the result of set
53: (4)                 operations may contain both representations of the same edge.
54: (0)             EdgeDataView
55: (0)             ============
56: (4)                 Edge data can be reported using an EdgeDataView typically created
57: (4)                 by calling an EdgeView: `DV = G.edges(data='weight', default=1)`.
58: (4)                 The EdgeDataView allows iteration over edge tuples, membership checking
59: (4)                 but no set operations.
60: (4)                 Iteration depends on `data` and `default` and for multigraph `keys`
61: (4)                 If `data is False` (the default) then iterate over 2-tuples `(u, v)`.
```

```
62: (4)                 If `data is True` iterate over 3-tuples `(u, v, datadict)`.
63: (4)                 Otherwise iterate over `(u, v, datadict.get(data, default))`.
64: (4)                 For Multigraphs, if `keys is True`, replace `u, v` with `u, v, key`
65: (4)                 to create 3-tuples and 4-tuples.
66: (4)                 The argument `nbunch` restricts edges to those incident to nodes in
nbunch.
67: (0)             """

229: (4)                The main use for this class is to iterate through node-data pairs.
230: (4)                The data can be the entire data-dictionary for each node, or it
231: (4)                can be a specific attribute (with default) for each node.
232: (4)                Set operations are enabled with NodeDataView, but don't work in
233: (4)                cases where the data is not hashable. Use with caution.
234: (4)                Typically, set operations on nodes use NodeView, not NodeDataView.
235: (4)                That is, they use `G.nodes` instead of `G.nodes(data='foo')`.
236: (4)                Parameters

(4)                 """A EdgeDataView class for edges of Graph
(4)                 This view is primarily used to iterate over the edges reporting
(4)                 edges as node-tuples with edge data optionally reported. The
(4)                 argument `nbunch` allows restriction to edges incident to nodes
(4)                 in that container/singleton. The default (nbunch=None)
(4)                 reports all edges. The arguments `data` and `default` control
(4)                 what edge data is reported. The default `data is False` reports
(4)                 only node-tuples for each edge. If `data is True` the entire edge
(4)                 data dict is returned. Otherwise `data` is assumed to hold the name
(4)                 of the edge attribute to report with default `default` if  that
(4)                 edge attribute is not present.
(4)                 Parameters
(4)                 ----------
(4)                 nbunch : container of nodes, node or None (default None)
(4)                 data : False, True or string (default False)
(4)                 default : default value (default None)

907: (8)                    Return a read-only view of edge data.
908: (8)                    Parameters
909: (8)                    ----------
910: (8)                    data : bool or edge attribute key
911: (12)                       If ``data=True``, then the data view maps each edge to a
dictionary
912: (12)                       containing all of its attributes. If `data` is a key in the edge
913: (12)                       dictionary, then the data view maps each edge to its value for
914: (12)                       the keyed attribute. In this case, if the edge doesn't have the
915: (12)                       attribute, the `default` value is returned.
916: (8)                    default : object, default=None
917: (12)                       The value used when an edge does not have a specific attribute
918: (8)                    nbunch : container of nodes, optional (default=None)
919: (12)                       Allows restriction to edges only involving certain nodes. All
edges
920: (12)                       are considered by default.
921: (8)                    Returns
922: (8)                    -------
923: (8)                    dataview
924: (12)                       Returns an `EdgeDataView` for undirected Graphs, `OutEdgeDataView`
925: (12)                       for DiGraphs, `MultiEdgeDataView` for MultiGraphs and
926: (12)                       `OutMultiEdgeDataView` for MultiDiGraphs.
927: (8)                    Notes
928: (8)                    -----
929: (8)                    If ``data=False``, returns an `EdgeView` without any edge data.
930: (8)                    See Also
931: (8)                    --------
932: (8)                    EdgeDataView
933: (8)                    OutEdgeDataView
934: (8)                    MultiEdgeDataView
```

```
935: (8)                    OutMultiEdgeDataView
936: (8)                    Examples
937: (8)                    --------
938: (8)                    >>> G = nx.Graph()
939: (8)                    >>> G.add_edges_from(
940: (8)                    ...     [
941: (8)                    ...         (0, 1, {"dist": 3, "capacity": 20}),
942: (8)                    ...         (1, 2, {"dist": 4}),
943: (8)                    ...         (2, 0, {"dist": 5}),
944: (8)                    ...     ]
945: (8)                    ... )
946: (8)                    Accessing edge data with ``data=True`` (the default) returns an
947: (8)                    edge data view object listing each edge with all of its attributes:
948: (8)                    >>> G.edges.data()
949: (8)                    EdgeDataView([(0, 1, {'dist': 3, 'capacity': 20}), (0, 2, {'dist':
5}), (1, 2, {'dist': 4})])
950: (8)                    If `data` represents a key in the edge attribute dict, a dataview
listing
951: (8)                    each edge with its value for that specific key is returned:
952: (8)                    >>> G.edges.data("dist")
953: (8)                    EdgeDataView([(0, 1, 3), (0, 2, 5), (1, 2, 4)])
954: (8)                    `nbunch` can be used to limit the edges:
955: (8)                    >>> G.edges.data("dist", nbunch=[0])
956: (8)                    EdgeDataView([(0, 1, 3), (0, 2, 5)])
957: (8)                    If a specific key is not found in an edge attribute dict, the value
958: (8)                    specified by `default` is used:
959: (8)                    >>> G.edges.data("capacity")
960: (8)                    EdgeDataView([(0, 1, 20), (0, 2, None), (1, 2, None)])
961: (8)                    Note that there is no check that the `data` key is present in any of
962: (8)                    the edge attribute dictionaries:
963: (8)                    >>> G.edges.data("speed")
964: (8)                    EdgeDataView([(0, 1, None), (0, 2, None), (1, 2, None)])
965: (8)                    """
966: (8)                    if nbunch is None and data is False:

973: (0)            class EdgeView(OutEdgeView):
974: (4)                """A EdgeView class for edges of a Graph
975: (4)                This densely packed View allows iteration over edges, data lookup
976: (4)                like a dict and set operations on edges represented by node-tuples.
977: (4)                In addition, edge data can be controlled by calling this object
978: (4)                possibly creating an EdgeDataView. Typically edges are iterated over
979: (4)                and reported as `(u, v)` node tuples or `(u, v, key)` node/key tuples
980: (4)                for multigraphs. Those edge representations can also be using to
981: (4)                lookup the data dict for any edge. Set operations also are available
982: (4)                where those tuples are the elements of the set.
983: (4)                Calling this object with optional arguments `data`, `default` and `keys`
984: (4)                controls the form of the tuple (see EdgeDataView). Optional argument
985: (4)                `nbunch` allows restriction to edges only involving certain nodes.
986: (4)                If `data is False` (the default) then iterate over 2-tuples `(u, v)`.
987: (4)                If `data is True` iterate over 3-tuples `(u, v, datadict)`.
988: (4)                Otherwise iterate over `(u, v, datadict.get(data, default))`.
989: (4)                For Multigraphs, if `keys is True`, replace `u, v` with `u, v, key` above.
990: (4)                Parameters
991: (4)                ==========
992: (4)                graph : NetworkX graph-like class
993: (4)                nbunch : (default= all nodes in graph) only report edges with these nodes
994: (4)                keys : (only for MultiGraph. default=False) report edge key in tuple
995: (4)                data : bool or string (default=False) see above

```
    nodes (0.01) and "temperature" of 0.1 to ensure nodes don't fly away.
    During the simulation, `k` helps determine the distance between nodes,
    though `scale` and `center` determine the size and place after
    rescaling occurs at the end of the simulation.
    Fixing some nodes doesn't allow them to move in the simulation.
    It also turns off the rescaling feature at the simulation's end.
    In addition, setting `scale` to `None` turns off rescaling.
    Parameters
    ----------
    G : NetworkX graph or list of nodes
        A position will be assigned to every node in G.
    k : float (default=None)
        Optimal distance between nodes.  If None the distance is set to
        1/sqrt(n) where n is the number of nodes.  Increase this value
        to move nodes farther apart.
    pos : dict or None  optional (default=None)
        Initial positions for nodes as a dictionary with node as keys
        and values as a coordinate list or tuple.  If None, then use
        random initial positions.
    fixed : list or None  optional (default=None)
        Nodes to keep fixed at initial position.
        Nodes not in ``G.nodes`` are ignored.
        ValueError raised if `fixed` specified and `pos` not.
    iterations : int  optional (default=50)
        Maximum number of iterations taken
    threshold: float optional (default = 1e-4)
        Threshold for relative error in node position changes.
        The iteration stops if the error is below this threshold.
    weight : string or None   optional (default='weight')
        The edge attribute that holds the numerical value used for
        the edge weight.  Larger means a stronger attractive force.
        If None, then all edge weights are 1.
    scale : number or None (default: 1)
        Scale factor for positions. Not used unless `fixed is None`.
        If scale is None, no rescaling is performed.
    center : array-like or None
        Coordinate pair around which to center the layout.
        Not used unless `fixed is None`.
    dim : int
        Dimension of layout.
    seed : int, RandomState instance or None  optional (default=None)
        Set the random state for deterministic node layouts.
        If int, `seed` is the seed used by the random number generator,
        if numpy.random.RandomState instance, `seed` is the random
        number generator,
        if None, the random number generator is the RandomState instance used
        by numpy.random.
    Returns
    -------
    pos : dict
        A dictionary of positions keyed by node
    Examples
    --------
    >>> G = nx.path_graph(4)
    >>> pos = nx.spring_layout(G)
    >>> pos = nx.fruchterman_reingold_layout(G)
    """

3: (0)              LaTeX
4: (0)              *****
5: (0)              Export NetworkX graphs in LaTeX format using the TikZ library within
TeX/LaTeX.
6: (0)              Usually, you will want the drawing to appear in a figure environment so
7: (0)              you use ``to_latex(G, caption="A caption")``. If you want the raw
8: (0)              drawing commands without a figure environment use :func:`to_latex_raw`.
9: (0)              And if you want to write to a file instead of just returning the latex
10: (0)             code as a string, use ``write_latex(G, "filename.tex", caption="A caption")``.
11: (0)             To construct a figure with subfigures for each graph to be shown, provide
12: (0)             ``to_latex`` or ``write_latex`` a list of graphs, a list of subcaptions,
13: (0)             and a number of rows of subfigures inside the figure.
14: (0)             To be able to refer to the figures or subfigures in latex using ``\\ref``,
15: (0)             the keyword ``latex_label`` is available for figures and `sub_labels` for
16: (0)             a list of labels, one for each subfigure.
17: (0)             We intend to eventually provide an interface to the TikZ Graph
18: (0)             features which include e.g. layout algorithms.
19: (0)             Let us know via github what you'd like to see available, or better yet
20: (0)             give us some code to do it, or even better make a github pull request
21: (0)             to add the feature.
22: (0)             The TikZ approach
23: (0)             ================
24: (0)             Drawing options can be stored on the graph as node/edge attributes, or
25: (0)             can be provided as dicts keyed by node/edge to a string of the options
26: (0)             for that node/edge. Similarly a label can be shown for each node/edge
27: (0)             by specifying the labels as graph node/edge attributes or by providing
28: (0)             a dict keyed by node/edge to the text to be written for that node/edge.
29: (0)             Options for the tikzpicture environment (e.g. "[scale=2]") can be provided
30: (0)             via a keyword argument. Similarly default node and edge options can be
31: (0)             provided through keywords arguments. The default node options are applied
32: (0)             to the single TikZ "path" that draws all nodes (and no edges). The default
edge
33: (0)             options are applied to a TikZ "scope" which contains a path for each edge.
34: (0)             Examples
35: (0)             ========
36: (0)             >>> G = nx.path_graph(3)
37: (0)             >>> nx.write_latex(G, "just_my_figure.tex", as_document=True)
38: (0)             >>> nx.write_latex(G, "my_figure.tex", caption="A path graph",
latex_label="fig1")
39: (0)             >>> latex_code = nx.to_latex(G)  # a string rather than a file
40: (0)             You can change many features of the nodes and edges.
41: (0)             >>> G = nx.path_graph(4, create_using=nx.DiGraph)
42: (0)             >>> pos = {n: (n, n) for n in G}  # nodes set on a line
43: (0)             >>> G.nodes[0]["style"] = "blue"
44: (0)             >>> G.nodes[2]["style"] = "line width=3,draw"
45: (0)             >>> G.nodes[3]["label"] = "Stop"
46: (0)             >>> G.edges[(0, 1)]["label"] = "1st Step"
47: (0)             >>> G.edges[(0, 1)]["label_opts"] = "near start"
48: (0)             >>> G.edges[(1, 2)]["style"] = "line width=3"
49: (0)             >>> G.edges[(1, 2)]["label"] = "2nd Step"
50: (0)             >>> G.edges[(2, 3)]["style"] = "green"
51: (0)             >>> G.edges[(2, 3)]["label"] = "3rd Step"
52: (0)             >>> G.edges[(2, 3)]["label_opts"] = "near end"
53: (0)             >>> nx.write_latex(G, "latex_graph.tex", pos=pos, as_document=True)
54: (0)             Then compile the LaTeX using something like ``pdflatex latex_graph.tex``
55: (0)             and view the pdf file created: ``latex_graph.pdf``.
56: (0)             If you want **subfigures** each containing one graph, you can input a list of
```

```
graphs.
57: (0)             >>> H1 = nx.path_graph(4)
58: (0)             >>> H2 = nx.complete_graph(4)
59: (0)             >>> H3 = nx.path_graph(8)
60: (0)             >>> H4 = nx.complete_graph(8)
61: (0)             >>> graphs = [H1, H2, H3, H4]
62: (0)             >>> caps = ["Path 4", "Complete graph 4", "Path 8", "Complete graph 8"]
63: (0)             >>> lbls = ["fig2a", "fig2b", "fig2c", "fig2d"]

    """Return a string of the LaTeX/TikZ code to draw `G`
    This function produces just the code for the tikzpicture
    without any enclosing environment.
    Parameters
    ==========
    G : NetworkX graph
        The NetworkX graph to be drawn
    pos : string or dict (default "pos")
        The name of the node attribute on `G` that holds the position of each node.

        Positions can be sequences of length 2 with numbers for (x,y) coordinates.

        They can also be strings to denote positions in TikZ style, such as (x, y)

        or (angle:radius).
        If a dict, it should be keyed by node to a position.
        If an empty dict, a circular layout is computed by TikZ.
    tikz_options : string
        The tikzpicture options description defining the options for the picture.

        Often large scale options like `[scale=2]`.
    default_node_options : string
        The draw options for a path of nodes. Individual node options override these.
    node_options : string or dict
        The name of the node attribute on `G` that holds the options for each node.

        Or a dict keyed by node to a string holding the options for that node.
    node_label : string or dict
        The name of the node attribute on `G` that holds the node label (text)
        displayed for each node. If the attribute is "" or not present, the node

        itself is drawn as a string. LaTeX processing such as ``"$A_1$"`` is allowed.

        Or a dict keyed by node to a string holding the label for that node.
    default_edge_options : string
        The options for the scope drawing all edges. The default is "[-]" for
        undirected graphs and "[->]" for directed graphs.
    edge_options : string or dict
        The name of the edge attribute on `G` that holds the options for each edge.

        If the edge is a self-loop and ``"loop" not in edge_options`` the option

        "loop," is added to the options for the self-loop edge. Hence you can
        use "[loop above]" explicitly, but the default is "[loop]".
        Or a dict keyed by edge to a string holding the options for that edge.
    edge_label : string or dict
        The name of the edge attribute on `G` that holds the edge label (text)
        displayed for each edge. If the attribute is "" or not present, no edge

        label is drawn.
        Or a dict keyed by edge to a string holding the label for that edge.
    edge_label_options : string or dict
        The name of the edge attribute on `G` that holds the label options for
        each edge. For example, "[sloped,above,blue]". The default is no options.

        Or a dict keyed by edge to a string holding the label options for that edge.

    Returns
    =======
```

```
(4)                 latex_code : string
(7)                    The text string which draws the desired graph(s) when compiled by LaTeX.
(4)                 See Also
(4)                 ========

282: (4)                or ``\\input`` statements.
283: (4)                Parameters
284: (4)                ==========
285: (4)                Gbunch : NetworkX graph or iterable of NetworkX graphs
286: (8)                    The NetworkX graph to be drawn or an iterable of graphs
287: (8)                    to be drawn inside subfigures of a single figure.
288: (4)                pos : string or list of strings
289: (8)                    The name of the node attribute on `G` that holds the position of each
node.
290: (8)                    Positions can be sequences of length 2 with numbers for (x,y)
coordinates.
291: (8)                    They can also be strings to denote positions in TikZ style, such as
(x, y)
292: (8)                    or (angle:radius).
293: (8)                    If a dict, it should be keyed by node to a position.
294: (8)                    If an empty dict, a circular layout is computed by TikZ.
295: (8)                    If you are drawing many graphs in subfigures, use a list of position
dicts.
296: (4)                tikz_options : string
297: (8)                    The tikzpicture options description defining the options for the
picture.
298: (8)                    Often large scale options like `[scale=2]`.
299: (4)                default_node_options : string
300: (8)                    The draw options for a path of nodes. Individual node options override
```

```
these.
    node_options : string or dict
        The name of the node attribute on `G` that holds the options for each node.

        Or a dict keyed by node to a string holding the options for that node.
    node_label : string or dict
        The name of the node attribute on `G` that holds the node label (text)
        displayed for each node. If the attribute is "" or not present, the node
        itself is drawn as a string. LaTeX processing such as ``"$A_1$"`` is allowed.

        Or a dict keyed by node to a string holding the label for that node.
    default_edge_options : string
        The options for the scope drawing all edges. The default is "[-]" for
        undirected graphs and "[->]" for directed graphs.
    edge_options : string or dict
        The name of the edge attribute on `G` that holds the options for each edge.

        If the edge is a self-loop and ``"loop" not in edge_options`` the option
        "loop," is added to the options for the self-loop edge. Hence you can
        use "[loop above]" explicitly, but the default is "[loop]".
        Or a dict keyed by edge to a string holding the options for that edge.
    edge_label : string or dict
        The name of the edge attribute on `G` that holds the edge label (text)
        displayed for each edge. If the attribute is "" or not present, no edge
        label is drawn.
        Or a dict keyed by edge to a string holding the label for that edge.
    edge_label_options : string or dict
        The name of the edge attribute on `G` that holds the label options for
        each edge. For example, "[sloped,above,blue]". The default is no options.
        Or a dict keyed by edge to a string holding the label options for that edge.
    caption : string
        The caption string for the figure environment
    latex_label : string
        The latex label used for the figure for easy referral from the main text
    sub_captions : list of strings
        The sub_caption string for each subfigure in the figure
    sub_latex_labels : list of strings
        The latex label for each subfigure in the figure
    n_rows : int
        The number of rows of subfigures to arrange for multiple graphs
    as_document : bool
        Whether to wrap the latex code in a document environment for compiling
    document_wrapper : formatted text string with variable ``content``.
        This text is called to evaluate the content embedded in a document
        environment with a preamble setting up TikZ.
    figure_wrapper : formatted text string
        This text is evaluated with variables ``content``, ``caption`` and ``label``.
        It wraps the content and if a caption is provided, adds the latex code for
        that caption, and if a label is provided, adds the latex code for a label.
    subfigure_wrapper : formatted text string
        This text evaluate variables ``size``, ``content``, ``caption`` and ``label``.
        It wraps the content and if a caption is provided, adds the latex code for
        that caption, and if a label is provided, adds the latex code for a label.
        The size is the vertical size of each row of subfigures as a fraction.
    Returns
    =======
    latex_code : string
```

```
354: (8)                    The text string which draws the desired graph(s) when compiled by
LaTeX.

415: (4)                This convenience function creates the latex drawing code as a string
416: (4)                and writes that to a file ready to be compiled when `as_document` is True
417: (4)                or ready to be ``import`` ed or ``include`` ed into your main LaTeX
document.
```

```
    The `path` argument can be a string filename or a file handle to write to.
    Parameters
    ----------
    Gbunch : NetworkX graph or iterable of NetworkX graphs
        If Gbunch is a graph, it is drawn in a figure environment.
        If Gbunch is an iterable of graphs, each is drawn in a subfigure
        environment within a single figure environment.
    path : filename
        Filename or file handle to write to
    options : dict
        By default, TikZ is used with options: (others are ignored)::
            pos : string or dict or list
                The name of the node attribute on `G` that holds the position of each node.

                Positions can be sequences of length 2 with numbers for (x,y) coordinates.

                They can also be strings to denote positions in TikZ style, such as (x, y)

                or (angle:radius).
                If a dict, it should be keyed by node to a position.
                If an empty dict, a circular layout is computed by TikZ.
                If you are drawing many graphs in subfigures, use a list of position dicts.
            tikz_options : string
                The tikzpicture options description defining the options for the picture.

                Often large scale options like `[scale=2]`.
            default_node_options : string
                The draw options for a path of nodes. Individual node options override these.
            node_options : string or dict
                The name of the node attribute on `G` that holds the options for each node.

                Or a dict keyed by node to a string holding the options for that node.
            node_label : string or dict
                The name of the node attribute on `G` that holds the node label (text)

                displayed for each node. If the attribute is "" or not present, the node

                itself is drawn as a string. LaTeX processing such as ``"$A_1$"`` is allowed.

                Or a dict keyed by node to a string holding the label for that node.
            default_edge_options : string
                The options for the scope drawing all edges. The default is "[-]" for

                undirected graphs and "[->]" for directed graphs.
            edge_options : string or dict
                The name of the edge attribute on `G` that holds the options for each edge.

                If the edge is a self-loop and ``"loop" not in edge_options`` the option

                "loop," is added to the options for the self-loop edge. Hence you can

                use "[loop above]" explicitly, but the default is "[loop]".
                Or a dict keyed by edge to a string holding the options for that edge.
            edge_label : string or dict
                The name of the edge attribute on `G` that holds the edge label (text)

                displayed for each edge. If the attribute is "" or not present, no edge

                label is drawn.

141: (8)                    Draw only specified nodes
142: (4)                edgelist : list (default=list(G.edges()))
143: (8)                    Draw only specified edges
144: (4)                node_size : scalar or array (default=300)
145: (8)                    Size of nodes.  If an array is specified it must be the
146: (8)                    same length as nodelist.
147: (4)                node_color : color or array of colors (default='#1f78b4')
148: (8)                    Node color. Can be a single color or a sequence of colors with the
same
149: (8)                    length as nodelist. Color can be string or rgb (or rgba) tuple of
150: (8)                    floats from 0-1. If numeric values are specified they will be
151: (8)                    mapped to colors using the cmap and vmin,vmax parameters. See
152: (8)                    matplotlib.scatter for more details.
153: (4)                node_shape :  string (default='o')
154: (8)                    The shape of the node.  Specification is as matplotlib.scatter
155: (8)                    marker, one of 'so^>v<dph8'.
```

```
    alpha : float or None (default=None)
        The node and edge transparency
    cmap : Matplotlib colormap, optional
        Colormap for mapping intensities of nodes
    vmin,vmax : float, optional
        Minimum and maximum for node colormap scaling
    linewidths : scalar or sequence (default=1.0)
        Line width of symbol border
    width : float or array of floats (default=1.0)
        Line width of edges
    edge_color : color or array of colors (default='k')
        Edge color. Can be a single color or a sequence of colors with the same

        length as edgelist. Color can be string or rgb (or rgba) tuple of
        floats from 0-1. If numeric values are specified they will be
        mapped to colors using the edge_cmap and edge_vmin,edge_vmax parameters.
    edge_cmap : Matplotlib colormap, optional
        Colormap for mapping intensities of edges
    edge_vmin,edge_vmax : floats, optional
        Minimum and maximum for edge colormap scaling
    style : string (default=solid line)
        Edge line style e.g.: '-', '--', '-.', ':'
        or words like 'solid' or 'dashed'.
        (See `matplotlib.patches.FancyArrowPatch`: `linestyle`)
    labels : dictionary (default=None)
        Node labels in a dictionary of text labels keyed by node
    font_size : int (default=12 for nodes, 10 for edges)
        Font size for text labels
    font_color : color (default='k' black)
        Font color string. Color can be string or rgb (or rgba) tuple of
        floats from 0-1.
    font_weight : string (default='normal')
        Font weight
    font_family : string (default='sans-serif')
        Font family
    label : string, optional
        Label for graph legend
    hide_ticks : bool, optional
        Hide ticks of axes. When `True` (the default), ticks and ticklabels
        are removed from the axes. To set ticks and tick labels to the pyplot default,

        use ``hide_ticks=False``.
    kwds : optional keywords
        See networkx.draw_networkx_nodes(), networkx.draw_networkx_edges(), and

        networkx.draw_networkx_labels() for a description of optional keywords.
    Notes
    -----
    For directed graphs, arrows  are drawn at the head end.  Arrows can be
    turned off with keyword arrows=False.
    Examples
    --------
    >>> G = nx.dodecahedral_graph()
    >>> nx.draw(G)
    >>> nx.draw(G, pos=nx.spring_layout(G))  # use spring layout
    >>> import matplotlib.pyplot as plt
    >>> limits = plt.axis("off")  # turn off axis
    Also see the NetworkX drawing examples at
    https://networkx.org/documentation/latest/auto_examples/index.html

    r"""Draw the edges of the graph G.
    This draws only the edges of the graph G.
    Parameters
    ----------
    G : graph
        A networkx graph
    pos : dictionary
        A dictionary with nodes as keys and positions as values.
        Positions should be sequences of length 2.
    edgelist : collection of edge tuples (default=G.edges())
        Draw only specified edges
    width : float or array of floats (default=1.0)
        Line width of edges
    edge_color : color or array of colors (default='k')
        Edge color. Can be a single color or a sequence of colors with the same
        length as edgelist. Color can be string or rgb (or rgba) tuple of
        floats from 0-1. If numeric values are specified they will be
        mapped to colors using the edge_cmap and edge_vmin,edge_vmax parameters.
    style : string or array of strings (default='solid')
        Edge line style e.g.: '-', '--', '-.', ':'
        or words like 'solid' or 'dashed'.
        Can be a single style or a sequence of styles with the same
        length as the edge list.
        If less styles than edges are given the styles will cycle.
        If more styles than edges are given the styles will be used sequentially
        and not be exhausted.
        Also, `(offset, onoffseq)` tuples can be used as style instead of a strings.
        (See `matplotlib.patches.FancyArrowPatch`: `linestyle`)
    alpha : float or array of floats (default=None)
        The edge transparency.  This can be a single alpha value,
        in which case it will be applied to all specified edges. Otherwise,
        if it is an array, the elements of alpha will be applied to the colors
        in order (cycling through alpha multiple times if necessary).
    edge_cmap : Matplotlib colormap, optional
        Colormap for mapping intensities of edges
    edge_vmin,edge_vmax : floats, optional
        Minimum and maximum for edge colormap scaling
    ax : Matplotlib Axes object, optional
        Draw the graph in the specified Matplotlib axes.
    arrows : bool or None, optional (default=None)
        If `None`, directed graphs draw arrowheads with
        `~matplotlib.patches.FancyArrowPatch`, while undirected graphs draw edges
        via `~matplotlib.collections.LineCollection` for speed.
        If `True`, draw arrowheads with FancyArrowPatches (bendable and stylish).
```

```
(8)                 If `False`, draw edges using LineCollection (linear and fast).
(8)                 Note: Arrowheads will be the same color as edges.
(4)             arrowstyle : str (default='-\|>' for directed graphs)
(8)                 For directed graphs and `arrows==True` defaults to '-\|>',
(8)                 For undirected graphs default to '-'.
(8)                 See `matplotlib.patches.ArrowStyle` for more options.
(4)             arrowsize : int (default=10)
(8)                 For directed graphs, choose the size of the arrow head's length and
(8)                 width. See `matplotlib.patches.FancyArrowPatch` for attribute
(8)                 `mutation_scale` for more info.
(4)             connectionstyle : string or iterable of strings (default="arc3")
(8)                 Pass the connectionstyle parameter to create curved arc of rounding
(8)                 radius rad. For example, connectionstyle='arc3,rad=0.2'.
(8)                 See `matplotlib.patches.ConnectionStyle` and
(8)                 `matplotlib.patches.FancyArrowPatch` for more info.
(8)                 If Iterable, index indicates i'th edge key of MultiGraph
(4)             node_size : scalar or array (default=300)
(8)                 Size of nodes. Though the nodes are not drawn with this function, the
(8)                 node size is used in determining edge positioning.
(4)             nodelist : list, optional (default=G.nodes())
(7)                This provides the node order for the `node_size` array (if it is an
array).
(4)             node_shape :  string (default='o')
(8)                 The marker used for nodes, used in determining edge positioning.
(8)                 Specification is as a `matplotlib.markers` marker, e.g. one of
'so^>v<dph8'.
(4)             label : None or string
(8)                 Label for legend
(4)             min_source_margin : int (default=0)
(8)                 The minimum margin (gap) at the beginning of the edge at the source.
(4)             min_target_margin : int (default=0)
(8)                 The minimum margin (gap) at the end of the edge at the target.
(4)             hide_ticks : bool, optional
(8)                 Hide ticks of axes. When `True` (the default), ticks and ticklabels
(8)                 are removed from the axes. To set ticks and tick labels to the pyplot
default,
(8)                 use ``hide_ticks=False``.
(4)             Returns
(4)             -------
(5)              matplotlib.collections.LineCollection or a list of
matplotlib.patches.FancyArrowPatch
(8)                 If ``arrows=True``, a list of FancyArrowPatches is returned.
(8)                 If ``arrows=False``, a LineCollection is returned.
(8)                 If ``arrows=None`` (the default), then a LineCollection is returned if
(8)                 `G` is undirected, otherwise returns a list of FancyArrowPatches.
(4)             Notes
(4)             -----
(4)             For directed graphs, arrows are drawn at the head end.  Arrows can be
(4)             turned off with keyword arrows=False or by passing an arrowstyle without
(4)             an arrow on the end.
(4)             Be sure to include `node_size` as a keyword argument; arrows are
(4)             drawn considering the size of nodes.
(4)             Self-loops are always drawn with `~matplotlib.patches.FancyArrowPatch`
(4)             regardless of the value of `arrows` or whether `G` is directed.
(4)             When ``arrows=False`` or ``arrows=None`` and `G` is undirected, the
(4)             FancyArrowPatches corresponding to the self-loops are not explicitly
(4)             returned. They should instead be accessed via the ``Axes.patches``
(4)             attribute (see examples).
(4)             Examples
(4)             --------
(4)             >>> G = nx.dodecahedral_graph()
(4)             >>> edges = nx.draw_networkx_edges(G, pos=nx.spring_layout(G))
(4)             >>> G = nx.DiGraph()
(4)             >>> G.add_edges_from([(1, 2), (1, 3), (2, 3)])
(4)             >>> arcs = nx.draw_networkx_edges(G, pos=nx.spring_layout(G))
(4)             >>> alphas = [0.3, 0.4, 0.5]
(4)             >>> for i, arc in enumerate(arcs):  # change alpha values of arcs
(4)             ...     arc.set_alpha(alphas[i])
(4)             The FancyArrowPatches corresponding to self-loops are not always
```

```
    returned, but can always be accessed via the ``patches`` attribute of the
    `matplotlib.Axes` object.
    >>> import matplotlib.pyplot as plt
    >>> fig, ax = plt.subplots()
    >>> G = nx.Graph([(0, 1), (0, 0)])  # Self-loop at node 0
    >>> edge_collection = nx.draw_networkx_edges(G, pos=nx.circular_layout(G), ax=ax)
    >>> self_loop_fap = ax.patches[0]

859: (4)                Parameters
860: (4)                ----------
861: (4)                G : graph
862: (8)                    A networkx graph
863: (4)                pos : dictionary
864: (8)                    A dictionary with nodes as keys and positions as values.
865: (8)                    Positions should be sequences of length 2.
866: (4)                labels : dictionary (default={n: n for n in G})
867: (8)                    Node labels in a dictionary of text labels keyed by node.
868: (8)                    Node-keys in labels should appear as keys in `pos`.
869: (8)                    If needed use: `{n:lab for n,lab in labels.items() if n in pos}`
870: (4)                font_size : int (default=12)
871: (8)                    Font size for text labels
872: (4)                font_color : color (default='k' black)
873: (8)                    Font color string. Color can be string or rgb (or rgba) tuple of
874: (8)                    floats from 0-1.
```

```
    font_weight : string (default='normal')
        Font weight
    font_family : string (default='sans-serif')
        Font family
    alpha : float or None (default=None)
        The text transparency
    bbox : Matplotlib bbox, (default is Matplotlib's ax.text default)
        Specify text box properties (e.g. shape, color etc.) for node labels.
    horizontalalignment : string (default='center')
        Horizontal alignment {'center', 'right', 'left'}
    verticalalignment : string (default='center')
        Vertical alignment {'center', 'top', 'bottom', 'baseline',
'center_baseline'}
    ax : Matplotlib Axes object, optional
        Draw the graph in the specified Matplotlib axes.
    clip_on : bool (default=True)
        Turn on clipping of node labels at axis boundaries
    hide_ticks : bool, optional
        Hide ticks of axes. When `True` (the default), ticks and ticklabels
        are removed from the axes. To set ticks and tick labels to the pyplot
default,
        use ``hide_ticks=False``.
    Returns
    -------
    dict
        `dict` of labels keyed on the nodes
    Examples
    --------
    >>> G = nx.dodecahedral_graph()
    >>> labels = nx.draw_networkx_labels(G, pos=nx.spring_layout(G))

(4)                 Parameters
(4)                 ----------
(4)                 G : graph
(8)                     A networkx graph
(4)                 pos : dictionary
(8)                     A dictionary with nodes as keys and positions as values.
(8)                     Positions should be sequences of length 2.
(4)                 edge_labels : dictionary (default=None)
(8)                     Edge labels in a dictionary of labels keyed by edge two-tuple.
(8)                     Only labels for the keys in the dictionary are drawn.
(4)                 label_pos : float (default=0.5)
(8)                     Position of edge label along edge (0=head, 0.5=center, 1=tail)
(4)                 font_size : int (default=10)
(8)                     Font size for text labels
(4)                 font_color : color (default='k' black)
(8)                     Font color string. Color can be string or rgb (or rgba) tuple of
(8)                     floats from 0-1.
(4)                 font_weight : string (default='normal')
(8)                     Font weight
(4)                 font_family : string (default='sans-serif')
(8)                     Font family
(4)                 alpha : float or None (default=None)
(8)                     The text transparency
(4)                 bbox : Matplotlib bbox, optional
(8)                     Specify text box properties (e.g. shape, color etc.) for edge labels.
(8)                     Default is {boxstyle='round', ec=(1.0, 1.0, 1.0), fc=(1.0, 1.0, 1.0)}.
(4)                 horizontalalignment : string (default='center')
(8)                     Horizontal alignment {'center', 'right', 'left'}
(4)                 verticalalignment : string (default='center')
(8)                     Vertical alignment {'center', 'top', 'bottom', 'baseline',
'center_baseline'}
(4)                 ax : Matplotlib Axes object, optional
(8)                     Draw the graph in the specified Matplotlib axes.
(4)                 rotate : bool (default=True)
(8)                     Rotate edge labels to lie parallel to edges
(4)                 clip_on : bool (default=True)
(8)                     Turn on clipping of edge labels at axis boundaries
(4)                 node_size : scalar or array (default=300)
(8)                     Size of nodes.  If an array it must be the same length as nodelist.
(4)                 nodelist : list, optional (default=G.nodes())
```

```
(7)                 This provides the node order for the `node_size` array (if it is an array).
(4)             connectionstyle : string or iterable of strings (default="arc3")
(8)                 Pass the connectionstyle parameter to create curved arc of rounding
(8)                 radius rad. For example, connectionstyle='arc3,rad=0.2'.
(8)                 See `matplotlib.patches.ConnectionStyle` and
(8)                 `matplotlib.patches.FancyArrowPatch` for more info.
(8)                 If Iterable, index indicates i'th edge key of MultiGraph
(4)             hide_ticks : bool, optional
(8)                 Hide ticks of axes. When `True` (the default), ticks and ticklabels
(8)                 are removed from the axes. To set ticks and tick labels to the pyplot default,
(8)                 use ``hide_ticks=False``.
(4)             Returns
(4)             -------
(4)             dict
(8)                 `dict` of labels keyed by edge

(4)                 -------
(4)                 NetworkX Graph of type create_using
(4)                 Examples
(4)                 --------
(4)                 Many well-known graph families are subfamilies of the circulant graphs;
(4)                 for example, to create the cycle graph on n points, we connect every
(4)                 node to nodes on either side (with offset plus or minus one). For n = 10,
(4)                 >>> G = nx.circulant_graph(10, [1])
(4)                 >>> edges = [
(4)                 ...     (0, 9),
(4)                 ...     (0, 1),
(4)                 ...     (1, 2),
(4)                 ...     (2, 3),
(4)                 ...     (3, 4),
(4)                 ...     (4, 5),
(4)                 ...     (5, 6),
(4)                 ...     (6, 7),
(4)                 ...     (7, 8),
(4)                 ...     (8, 9),
(4)                 ... ]
(4)                 >>> sorted(edges) == sorted(G.edges())
(4)                 True
(4)                 Similarly, we can create the complete graph
(4)                 on 5 points with the set of offsets [1, 2]:
(4)                 >>> G = nx.circulant_graph(5, [1, 2])
(4)                 >>> edges = [
(4)                 ...     (0, 1),
```

```
(4)                 ...     (0, 2),
(4)                 ...     (0, 3),
(4)                 ...     (0, 4),
(4)                 ...     (1, 2),
(4)                 ...     (1, 3),
(4)                 ...     (1, 4),
(4)                 ...     (2, 3),
(4)                 ...     (2, 4),
(4)                 ...     (3, 4),
(4)                 ... ]
