604: (0)               return (a,)
605: (0)           @array_function_dispatch(_qr_dispatcher)
606: (4)           def qr(a, mode='reduced'):
607: (4)               """
608: (4)               Compute the qr factorization of a matrix.
609: (4)               Factor the matrix `a` as *qr*, where `q` is orthonormal and `r` is
610: (4)               upper-triangular.
611: (4)               Parameters
612: (4)
613: (8)               a : array_like, shape (... , M, N)
614: (4)                   An array-like object with the dimensionality of at least 2.
615: (8)               mode : {'reduced', 'complete', 'r', 'raw'}, optional
616: (8)                   If K = min(M, N), then
617: (8)                     * 'reduced' : returns Q, R with dimensions (... , M, K), (... , K, N)
617: (8)                     * 'complete' : returns Q, R with dimensions (... , M, M), (... , M, N)

```

```

618: (8)          * 'r'           : returns R only with dimensions (... , K, N)
619: (8)          * 'raw'         : returns h, tau with dimensions (... , N, M), (... , K, )
620: (8)          The options 'reduced', 'complete', and 'raw' are new in numpy 1.8,
621: (8)          see the notes for more information. The default is 'reduced', and to
622: (8)          maintain backward compatibility with earlier versions of numpy both
623: (8)          it and the old default 'full' can be omitted. Note that array h
624: (8)          returned in 'raw' mode is transposed for calling Fortran. The
625: (8)          'economic' mode is deprecated. The modes 'full' and 'economic' may
626: (8)          be passed using only the first letter for backwards compatibility,
627: (8)          but all others must be spelled out. See the Notes for more
628: (8)          explanation.
629: (4)          Returns
630: (4)          -----
631: (4)          When mode is 'reduced' or 'complete', the result will be a namedtuple with
632: (4)          the attributes `Q` and `R`.
633: (4)          Q : ndarray of float or complex, optional
634: (8)          A matrix with orthonormal columns. When mode = 'complete' the
635: (8)          result is an orthogonal/unitary matrix depending on whether or not
636: (8)          a is real/complex. The determinant may be either +/- 1 in that
637: (8)          case. In case the number of dimensions in the input array is
638: (8)          greater than 2 then a stack of the matrices with above properties
639: (8)          is returned.
640: (4)          R : ndarray of float or complex, optional
641: (8)          The upper-triangular matrix or a stack of upper-triangular
642: (8)          matrices if the number of dimensions in the input array is greater
643: (8)          than 2.
644: (4)          (h, tau) : ndarrays of np.double or np.cdouble, optional
645: (8)          The array h contains the Householder reflectors that generate q
646: (8)          along with r. The tau array contains scaling factors for the
647: (8)          reflectors. In the deprecated 'economic' mode only h is returned.
648: (4)          Raises
649: (4)          -----
650: (4)          LinAlgError
651: (8)          If factoring fails.
652: (4)          See Also
653: (4)          -----
654: (4)          scipy.linalg.qr : Similar function in SciPy.
655: (4)          scipy.linalg.rq : Compute RQ decomposition of a matrix.
656: (4)
657: (4)
658: (4)          Notes
659: (4)          -----
660: (4)          This is an interface to the LAPACK routines ``dgeqr`` , ``zgeqr`` ,
661: (4)          ``dorgqr`` , and ``zungqr`` .
662: (4)          For more information on the qr factorization, see for example:
663: (4)          https://en.wikipedia.org/wiki/QR\_factorization
664: (4)          Subclasses of `ndarray` are preserved except for the 'raw' mode. So if
665: (4)          `a` is of type `matrix`, all the return values will be matrices too.
666: (4)          New 'reduced', 'complete', and 'raw' options for mode were added in
667: (4)          NumPy 1.8.0 and the old option 'full' was made an alias of 'reduced'. In
668: (4)          addition the options 'full' and 'economic' were deprecated. Because
669: (4)          'full' was the previous default and 'reduced' is the new default,
670: (4)          backward compatibility can be maintained by letting `mode` default.
671: (4)          The 'raw' option was added so that LAPACK routines that can multiply
672: (4)          arrays by q using the Householder reflectors can be used. Note that in
673: (4)          this case the returned arrays are of type np.double or np.cdouble and
674: (4)          the h array is transposed to be FORTRAN compatible. No routines using
675: (4)          the 'raw' return are currently exposed by numpy, but some are available
676: (4)          in lapack_lite and just await the necessary work.
677: (4)          Examples
678: (4)          -----
679: (4)          >>> a = np.random.randn(9, 6)
680: (4)          >>> Q, R = np.linalg.qr(a)
681: (4)          >>> np.allclose(a, np.dot(Q, R)) # a does equal QR
682: (4)          True
683: (4)          >>> R2 = np.linalg.qr(a, mode='r')
684: (4)          >>> np.allclose(R, R2) # mode='r' returns the same R as mode='full'
685: (4)          True
686: (4)          >>> a = np.random.normal(size=(3, 2, 2)) # Stack of 2 x 2 matrices as
687: (4)          input
688: (4)          >>> Q, R = np.linalg.qr(a)

```

```

686: (4)          >>> Q.shape
687: (4)          (3, 2, 2)
688: (4)          >>> R.shape
689: (4)          (3, 2, 2)
690: (4)          >>> np.allclose(a, np.matmul(Q, R))
691: (4)          True
692: (4)          Example illustrating a common use of `qr`: solving of least squares
693: (4)          problems
694: (4)          What are the least-squares-best `m` and `y0` in ``y = y0 + mx`` for
695: (4)          the following data: {(0,1), (1,0), (1,2), (2,1)}. (Graph the points
696: (4)          and you'll see that it should be  $y_0 = 0$ ,  $m = 1$ .) The answer is provided
697: (4)          by solving the over-determined matrix equation ``Ax = b``, where::
698: (6)          A = array([[0, 1], [1, 1], [1, 1], [2, 1]])
699: (6)          x = array([[y0], [m]])
700: (6)          b = array([[1], [0], [2], [1]])
701: (4)          If  $A = QR$  such that  $Q$  is orthonormal (which is always possible via
702: (4)          Gram-Schmidt), then `` $x = \text{inv}(R)^T \cdot (Q^T \cdot b)$ 
```

```

754: (8)             return wrap(a)
755: (4)             if mode == 'complete' and m > n:
756: (8)                 mc = m
757: (8)                 gufunc = _umath_linalg.qr_complete

791: (4)         eigvalsh : eigenvalues of real symmetric or complex Hermitian
792: (15)             (conjugate symmetric) arrays.
793: (4)         eigh : eigenvalues and eigenvectors of real symmetric or complex
794: (11)             Hermitian (conjugate symmetric) arrays.
795: (4)         scipy.linalg.eigvals : Similar function in SciPy.
796: (4)         Notes
797: (4)         -----
798: (4)         .. versionadded:: 1.8.0
799: (4)         Broadcasting rules apply, see the `numpy.linalg` documentation for
800: (4)         details.
801: (4)         This is implemented using the ``_geev`` LAPACK routines which compute
802: (4)         the eigenvalues and eigenvectors of general square arrays.
803: (4)         Examples
804: (4)         -----
805: (4)         Illustration, using the fact that the eigenvalues of a diagonal matrix
806: (4)         are its diagonal elements, that multiplying a matrix on the left
807: (4)         by an orthogonal matrix, `Q`, and on the right by `Q.T` (the transpose
808: (4)         of `Q`), preserves the eigenvalues of the "middle" matrix. In other
words,
809: (4)         if `Q` is orthogonal, then ``Q * A * Q.T`` has the same eigenvalues as
810: (4)         ``A``:
811: (4)         >>> from numpy import linalg as LA
812: (4)         >>> x = np.random.random()
813: (4)         >>> Q = np.array([[np.cos(x), -np.sin(x)], [np.sin(x), np.cos(x)]])
814: (4)         >>> LA.norm(Q[0, :]), LA.norm(Q[1, :]), np.dot(Q[0, :], Q[1, :])
815: (4)         (1.0, 1.0, 0.0)
816: (4)         Now multiply a diagonal matrix by ``Q`` on one side and by ``Q.T`` on the
other:
817: (4)         >>> D = np.diag((-1,1))
818: (4)         >>> LA.eigvals(D)
819: (4)         array([-1.,  1.])
820: (4)         >>> A = np.dot(Q, D)

```

959: (15)                               (conjugate symmetric) array.
960: (4)      scipy.linalg.eig : Similar function in SciPy that also solves the
961: (23)      generalized eigenvalue problem.
962: (4)      scipy.linalg.schur : Best choice for unitary and other non-Hermitian
963: (25)      normal matrices.

964: (4)      Notes
965: -----
966: (4)      .. versionadded:: 1.8.0
967: (4)      Broadcasting rules apply, see the `numpy.linalg` documentation for
968: (4)      details.
969: (4)      This is implemented using the ``_geev`` LAPACK routines which compute
970: (4)      the eigenvalues and eigenvectors of general square arrays.
971: (4)      The number `w` is an eigenvalue of `a` if there exists a vector `v` such
972: (4)      that ``a @ v = w * v``. Thus, the arrays `a`, `eigenvalues`, and
973: (4)      `eigenvectors` satisfy the equations ``a @ eigenvectors[:,i] =
974: (4)      eigenvalues[i] * eigenvectors[:,i]`` for :math:`i \in \{0, \dots, M-1\}`.
975: (4)      The array `eigenvectors` may not be of maximum rank, that is, some of the
976: (4)      columns may be linearly dependent, although round-off error may obscure
977: (4)      that fact. If the eigenvalues are all different, then theoretically the
978: (4)      eigenvectors are linearly independent and `a` can be diagonalized by a
979: (4)      similarity transformation using `eigenvectors`, i.e., ``inv(eigenvectors) @
980: (4)      a @ eigenvectors`` is diagonal.
981: (4)      For non-Hermitian normal matrices the SciPy function `scipy.linalg.schur`
982: (4)      is preferred because the matrix `eigenvectors` is guaranteed to be
983: (4)      unitary, which is not the case when using `eig`. The Schur factorization
984: (4)      produces an upper triangular matrix rather than a diagonal matrix, but for
985: (4)      normal matrices only the diagonal of the upper triangular matrix is
986: (4)      needed, the rest is roundoff error.
987: (4)      Finally, it is emphasized that `eigenvectors` consists of the *right* (as
988: (4)      in right-hand side) eigenvectors of `a`. A vector `y` satisfying ``y.T @ a
989: (4)      = z * y.T`` for some number `z` is called a *left* eigenvector of `a`,
990: (4)      and, in general, the left and right eigenvectors of a matrix are not
991: (4)      necessarily the (perhaps conjugate) transposes of each other.

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1231: (4) .. versionchanged:: 1.8.0
1232: (7) Broadcasting rules apply, see the `numpy.linalg` documentation for
1233: (7) details.
1234: (4) The decomposition is performed using LAPACK routine ``_gesdd``.
1235: (4) SVD is usually described for the factorization of a 2D matrix :math:`A`.
1236: (4) The higher-dimensional case will be discussed below. In the 2D case, SVD
is
1237: (4) written as :math:`A = U S V^H`, where :math:`A = a`, :math:`U= u`,
1238: (4) :math:`S= \sqrt{\text{np.diag}}(s)` and :math:`V^H = vh`. The 1D array `s`
1239: (4) contains the singular values of `a` and `u` and `vh` are unitary. The rows
1240: (4) of `vh` are the eigenvectors of :math:`A^H A` and the columns of `u` are
1241: (4) the eigenvectors of :math:`A A^H`. In both cases the corresponding
1242: (4) (possibly non-zero) eigenvalues are given by ``s**2``.
1243: (4) If `a` has more than two dimensions, then broadcasting rules apply, as
1244: (4) explained in :ref:`routines.linalg-broadcasting`. This means that SVD is
1245: (4) working in "stacked" mode: it iterates over all indices of the first
1246: (4) ``a.ndim - 2`` dimensions and for each combination SVD is applied to the
1247: (4) last two indices. The matrix `a` can be reconstructed from the
1248: (4) decomposition with either ``((u * s[..., None, :]) @ vh`` or
1249: (4) ``u @ (s[..., None] * vh)``. (The ``@`` operator can be replaced by the
1250: (4) function ``np.matmul`` for python versions below 3.5.)
1251: (4) If `a` is a ``matrix`` object (as opposed to an ``ndarray``), then so are
1252: (4) all the return values.
1253: (4) Examples
1254: (4) -----
1255: (4) >>> a = np.random.randn(9, 6) + 1j*np.random.randn(9, 6)
1256: (4) >>> b = np.random.randn(2, 7, 8, 3) + 1j*np.random.randn(2, 7, 8, 3)
1257: (4) Reconstruction based on full SVD, 2D case:
1258: (4) >>> U, S, Vh = np.linalg.svd(a, full_matrices=True)
1259: (4) >>> U.shape, S.shape, Vh.shape
1260: (4) ((9, 9), (6,), (6, 6))
1261: (4) >>> np.allclose(a, np.dot(U[:, :6] * S, Vh))
1262: (4) True
1263: (4) >>> smat = np.zeros((9, 6), dtype=complex)
1264: (4) >>> smat[:6, :6] = np.diag(S)
1265: (4) >>> np.allclose(a, np.dot(U, np.dot(smat, Vh)))
1266: (4) True
1267: (4) Reconstruction based on reduced SVD, 2D case:
1268: (4) >>> U, S, Vh = np.linalg.svd(a, full_matrices=False)
1269: (4) >>> U.shape, S.shape, Vh.shape
1270: (4) ((9, 6), (6,), (6, 6))
1271: (4) >>> np.allclose(a, np.dot(U * S, Vh))
1272: (4) True
1273: (4) >>> smat = np.diag(S)
1274: (4) >>> np.allclose(a, np.dot(U, np.dot(smat, Vh)))
1275: (4) True

1468: (4)            Returns
1469: (4)            -----
1470: (4)            rank : (...) array_like
1471: (8)              Rank of A.
1472: (4)            Notes
1473: (4)            -----
1474: (4)            The default threshold to detect rank deficiency is a test on the magnitude
1475: (4)            of the singular values of `A`. By default, we identify singular values
less
1476: (4)            than ``S.max() * max(M, N) * eps`` as indicating rank deficiency (with
1477: (4)            the symbols defined above). This is the algorithm MATLAB uses [1]. It
also
1478: (4)            appears in *Numerical recipes* in the discussion of SVD solutions for
linear
1479: (4)            least squares [2].
1480: (4)            This default threshold is designed to detect rank deficiency accounting
for
1481: (4)            the numerical errors of the SVD computation. Imagine that there is a
column
1482: (4)            in `A` that is an exact (in floating point) linear combination of other
1483: (4)            columns in `A`. Computing the SVD on `A` will not produce a singular value
1484: (4)            exactly equal to 0 in general: any difference of the smallest SVD value
from
1485: (4)            0 will be caused by numerical imprecision in the calculation of the SVD.
1486: (4)            Our threshold for small SVD values takes this numerical imprecision into
1487: (4)            account, and the default threshold will detect such numerical rank
deficiency. The threshold may declare a matrix `A` rank deficient even if
1488: (4)            the linear combination of some columns of `A` is not exactly equal to
1489: (4)            another column of `A` but only numerically very close to another column of
`A`.
1490: (4)            We chose our default threshold because it is in wide use. Other
thresholds
1491: (4)            are possible. For example, elsewhere in the 2007 edition of *Numerical
1492: (4)            recipes* there is an alternative threshold of ``S.max() *
1493: (4)            np.finfo(A.dtype).eps / 2. * np.sqrt(m + n + 1.)``. The authors describe
1494: (4)            this threshold as being based on "expected roundoff error" (p 71).
1495: (4)            The thresholds above deal with floating point roundoff error in the
1496: (4)
1497: (4)

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

1498: (4) calculation of the SVD. However, you may have more information about the  
 1499: (4) sources of error in `A` that would make you consider other tolerance  
 values

1500: (4) to detect \*effective\* rank deficiency. The most useful measure of the  
 1501: (4) tolerance depends on the operations you intend to use on your matrix. For  
 1502: (4) example, if your data come from uncertain measurements with uncertainties  
 1503: (4) greater than floating point epsilon, choosing a tolerance near that  
 1504: (4) uncertainty may be preferable. The tolerance may be absolute if the  
 1505: (4) uncertainties are absolute rather than relative.

1572: (4)           scipy.linalg.pinvh : Compute the (Moore-Penrose) pseudo-inverse of a
1573: (25)           Hermitian matrix.
1574: (4)           Notes
1575: (4)           -----
1576: (4)           The pseudo-inverse of a matrix A, denoted :math:`A^+`, is
1577: (4)           defined as: "the matrix that 'solves' [the least-squares problem]
1578: (4)           :math:`Ax = b`," i.e., if :math:`\bar{x}` is said solution, then
1579: (4)           :math:`A^+` is that matrix such that :math:`\bar{x} = A^+b`.
1580: (4)           It can be shown that if :math:`Q_1 \Sigma Q_2^T = A` is the singular
1581: (4)           value decomposition of A, then
1582: (4)           :math:`A^+ = Q_2 \Sigma^+ Q_1^T`, where :math:`Q_{1,2}` are
1583: (4)           orthogonal matrices, :math:`\Sigma` is a diagonal matrix consisting
1584: (4)           of A's so-called singular values, (followed, typically, by
1585: (4)           zeros), and then :math:`\Sigma^+` is simply the diagonal matrix
1586: (4)           consisting of the reciprocals of A's singular values
1587: (4)           (again, followed by zeros). [1]_

    """Compute a function of the singular values of the 2-D matrices in `x`.
    This is a private utility function used by `numpy.linalg.norm()`.

    Parameters
    -----
    x : ndarray
        The axes of `x` that hold the 2-D matrices.
    row_axis, col_axis : int
        The axes of `x` that hold the 2-D matrices.
    op : callable
        This should be either `numpy.amin` or `numpy.amax` or `numpy.sum`.

    Returns
    -----
    result : float or ndarray
        If `x` is 2-D, the return values is a float.
        Otherwise, it is an array with ``x.ndim - 2`` dimensions.
        The return values are either the minimum or maximum or sum of the
        singular values of the matrices, depending on whether `op`
        is `numpy.amin` or `numpy.amax` or `numpy.sum`.

    """
    y = moveaxis(x, (row_axis, col_axis), (-2, -1))
    result = op(svd(y, compute_uv=False), axis=-1)
    return result
def _norm_dispatcher(x, ord=None, axis=None, keepdims=None):
    return (x,)
@array_function_dispatch(_norm_dispatcher)
def norm(x, ord=None, axis=None, keepdims=False):
    """
    Matrix or vector norm.

    This function is able to return one of eight different matrix norms,
    or one of an infinite number of vector norms (described below), depending
    on the value of the ``ord`` parameter.

    Parameters
    -----
    x : array_like
        Input array. If `axis` is None, `x` must be 1-D or 2-D, unless `ord`
        is None. If both `axis` and `ord` are None, the 2-norm of
        ``x.ravel`` will be returned.
    ord : {non-zero int, inf, -inf, 'fro', 'nuc'}, optional
        Order of the norm (see table under ``Notes``). inf means numpy's
        `inf` object. The default is None.
    axis : {None, int, 2-tuple of ints}, optional.
        If `axis` is an integer, it specifies the axis of `x` along which to
        compute the vector norms. If `axis` is a 2-tuple, it specifies the
        axes that hold 2-D matrices, and the matrix norms of these matrices
        are computed. If `axis` is None then either a vector norm (when `x`
        is 1-D) or a matrix norm (when `x` is 2-D) is returned. The default
        is None.

2098: (4)             yield from arrays
2099: (4)             yield out
2100: (0)           @array_function_dispatch(_multidot_dispatcher)
2101: (0)           def multi_dot(arrays, *, out=None):
2102: (4)             """
2103: (4)             Compute the dot product of two or more arrays in a single function call,
2104: (4)             while automatically selecting the fastest evaluation order.
2105: (4)             `multi_dot` chains `numpy.dot` and uses optimal parenthesization
2106: (4)             of the matrices [1]_ [2]_. Depending on the shapes of the matrices,
2107: (4)             this can speed up the multiplication a lot.
2108: (4)             If the first argument is 1-D it is treated as a row vector.
2109: (4)             If the last argument is 1-D it is treated as a column vector.

```

```

2110: (4)           The other arguments must be 2-D.
2111: (4)           Think of `multi_dot` as::
2112: (8)             def multi_dot(arrays): return functools.reduce(np.dot, arrays)
2113: (4)           Parameters
2114: (4)             -----
2115: (4)             arrays : sequence of array_like
2116: (8)               If the first argument is 1-D it is treated as row vector.
2117: (8)               If the last argument is 1-D it is treated as column vector.
2118: (8)               The other arguments must be 2-D.
2119: (4)             out : ndarray, optional
2120: (8)               Output argument. This must have the exact kind that would be returned
2121: (8)               if it was not used. In particular, it must have the right type, must
be
2122: (8)               C-contiguous, and its dtype must be the dtype that would be returned
2123: (8)               for `dot(a, b)`. This is a performance feature. Therefore, if these
2124: (8)               conditions are not met, an exception is raised, instead of attempting
2125: (8)               to be flexible.
2126: (8)               .. versionadded:: 1.19.0
2127: (4)           Returns
2128: (4)             -----
2129: (4)             output : ndarray
2130: (8)               Returns the dot product of the supplied arrays.
2131: (4)           See Also
2132: (4)             -----
2133: (4)             numpy.dot : dot multiplication with two arguments.

524: (4)           Return the data of a masked array as an ndarray.
525: (4)           Return the data of `a` (if any) as an ndarray if `a` is a ``MaskedArray``,
526: (4)           else return `a` as a ndarray or subclass (depending on `subok`) if not.
Parameters
-----
529: (4)           a : array_like
530: (8)               Input ``MaskedArray``, alternatively a ndarray or a subclass thereof.
531: (4)           subok : bool
532: (8)               Whether to force the output to be a `pure` ndarray (False) or to
533: (8)               return a subclass of ndarray if appropriate (True, default).
See Also
-----
536: (4)           getmask : Return the mask of a masked array, or nomask.
537: (4)           getmaskarray : Return the mask of a masked array, or full array of False.
Examples
-----
540: (4)           >>> import numpy.ma as ma
541: (4)           >>> a = ma.masked_equal([[1,2],[3,4]], 2)
542: (4)           >>> a
543: (4)           masked_array(
544: (6)               data=[[1, --],
545: (12)                   [3, 4]],
546: (6)               mask=[[False,  True],
547: (12)                   [False, False]],
548: (6)               fill_value=2)
549: (4)           >>> ma.getdata(a)
550: (4)           array([[1, 2],
551: (11)               [3, 4]])
552: (4)           Equivalently use the ``MaskedArray`` `data` attribute.

```

```

553: (4)             >>> a.data
554: (4)             array([[1, 2],
555: (11)            [3, 4]])
556: (4)
557: (4)             """

"""
Mask using floating point equality.
Return a MaskedArray, masked where the data in array `x` are approximately
equal to `value`, determined using `isclose`. The default tolerances for
`masked_values` are the same as those for `isclose`.
For integer types, exact equality is used, in the same way as
`masked_equal`.
The fill_value is set to `value` and the mask is set to ``nomask`` if
possible.
Parameters
-----
x : array_like
    Array to mask.
value : float
    Masking value.
rtol, atol : float, optional
    Tolerance parameters passed on to `isclose`
copy : bool, optional
    Whether to return a copy of `x`.
shrink : bool, optional
    Whether to collapse a mask full of False to ``nomask``.
Returns
-----
result : MaskedArray
    The result of masking `x` where approximately equal to `value`.
See Also
-----
masked_where : Mask where a condition is met.
masked_equal : Mask where equal to a given value (integers).

class MaskedIterator:  

"""  

Flat iterator object to iterate over masked arrays.  

A `MaskedIterator` iterator is returned by ``x.flat`` for any masked array  

`x`. It allows iterating over the array as if it were a 1-D array,  

either in a for-loop or by calling its `next` method.  

Iteration is done in C-contiguous style, with the last index varying the  

fastest. The iterator can also be indexed using basic slicing or  

advanced indexing.  

See Also  

-----  

MaskedArray.flat : Return a flat iterator over an array.  

MaskedArray.flatten : Returns a flattened copy of an array.  

Notes  

-----  

`MaskedIterator` is not exported by the `ma` module. Instead of  

instantiating a `MaskedIterator` directly, use `MaskedArray.flat`.  

Examples  

-----  

>>> x = np.ma.array(arange(6).reshape(2, 3))  

>>> f1 = x.flat  

>>> type(f1)  

<class 'numpy.ma.core.MaskedIterator'>  

>>> for item in f1:  

...     print(item)  

...  

0  

1  

2  

3  

4  

5  

Extracting more than a single element b indexing the `MaskedIterator`  

returns a masked array:  

>>> f1[2:4]  

masked_array(data = [2 3],  

             mask = False,  

             fill_value = 999999)

2105: (0)         class MaskedArray(ndarray):
2106: (4)             """
2107: (4)             An array class with possibly masked values.
2108: (4)             Masked values of True exclude the corresponding element from any
2109: (4)             computation.
2110: (4)             Construction::
2111: (6)                 x = MaskedArray(data, mask=nomask, dtype=None, copy=False, subok=True,
2112: (22)                               ndmin=0, fill_value=None, keep_mask=True,
2113: (22)                               shrink=True, order=None)
2114: (4)             Parameters
2115: (4)             -----
2116: (4)             data : array_like
2117: (8)                 Input data.
2118: (4)             mask : sequence, optional
2119: (8)                 Mask. Must be convertible to an array of booleans with the same
2120: (8)                 shape as `data`. True indicates a masked (i.e. invalid) data.
2121: (4)             dtype : dtype, optional
2122: (8)                 Data type of the output.
2123: (8)                 If `dtype` is None, the type of the data argument (`data.dtype`)
2124: (8)                 is used. If `dtype` is not None and different from `data.dtype`,
2125: (8)                 a copy is performed.
2126: (4)             copy : bool, optional
2127: (8)                 Whether to copy the input data (True), or to use a reference instead.
2128: (8)                 Default is False.
2129: (4)             subok : bool, optional
2130: (8)                 Whether to return a subclass of `MaskedArray` if possible (True) or a
2131: (8)                 plain `MaskedArray`. Default is True.
2132: (4)             ndmin : int, optional
2133: (8)                 Minimum number of dimensions. Default is 0.
2134: (4)             fill_value : scalar, optional

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

2135: (8)           Value used to fill in the masked values when necessary.
2136: (8)           If None, a default based on the data-type is used.
2137: (4)           keep_mask : bool, optional
2138: (8)             Whether to combine `mask` with the mask of the input data, if any
2139: (8)             (True), or to use only `mask` for the output (False). Default is True.
2140: (4)           hard_mask : bool, optional
2141: (8)             Whether to use a hard mask or not. With a hard mask, masked values
2142: (8)             cannot be unmasked. Default is False.
2143: (4)           shrink : bool, optional
2144: (8)             Whether to force compression of an empty mask. Default is True.
2145: (4)           order : {'C', 'F', 'A'}, optional
2146: (8)             Specify the order of the array. If order is 'C', then the array
2147: (8)             will be in C-contiguous order (last-index varies the fastest).
2148: (8)             If order is 'F', then the returned array will be in
2149: (8)             Fortran-contiguous order (first-index varies the fastest).
2150: (8)             If order is 'A' (default), then the returned array may be
2151: (8)             in any order (either C-, Fortran-contiguous, or even discontiguous),
2152: (8)             unless a copy is required, in which case it will be C-contiguous.
2153: (4)           Examples
2154: (4)
2155: (4)           -----
2156: (4)             The ``mask`` can be initialized with an array of boolean values
2157: (4)             with the same shape as ``data``.
2158: (4)             >>> data = np.arange(6).reshape((2, 3))
2159: (4)             >>> np.ma.MaskedArray(data, mask=[[False, True, False],
2160: (4)                           ...                               [False, False, True]])
2161: (6)             masked_array(
2162: (12)               data=[[0, --, 2],
2163: (6)                 [3, 4, --]],
2164: (12)               mask=[[False, True, False],
2165: (6)                 [False, False, True]],
2166: (4)               fill_value=999999)
2167: (4)             Alternatively, the ``mask`` can be initialized to homogeneous boolean
2168: (4)             array with the same shape as ``data`` by passing in a scalar
2169: (4)             boolean value:
2170: (4)             >>> np.ma.MaskedArray(data, mask=False)
2171: (6)             masked_array(
2172: (12)               data=[[0, 1, 2],
2173: (6)                 [3, 4, 5]],
2174: (12)               mask=[[False, False, False],
2175: (6)                 [False, False, False]],
2176: (4)               fill_value=999999)
2177: (4)             >>> np.ma.MaskedArray(data, mask=True)
2178: (6)             masked_array(
2179: (12)               data=[[--, --, --],
2180: (6)                 [--, --, --]],
2181: (12)               mask=[[True, True, True],
2182: (6)                 [True, True, True]],
2183: (6)               fill_value=999999,
2184: (4)               dtype=int64)
2185: (4)             .. note::
2186: (4)               The recommended practice for initializing ``mask`` with a scalar
2187: (4)               boolean value is to use ``True``/``False`` rather than
2188: (4)               ``np.True_``/``np.False_``. The reason is :attr:`nomask`
2189: (4)               is represented internally as ``np.False_``.
2190: (4)               >>> np.False_ is np.ma.nomask

2418: (8)                                         Notes
2419: (8)                                         -----
2420: (8)                                         ``a.view()`` is used two different ways:
2421: (8)                                         ``a.view(some_dtype)`` or ``a.view(dtype=some_dtype)`` constructs a
view
2422: (8)                                         of the array's memory with a different data-type. This can cause a
2423: (8)                                         reinterpretation of the bytes of memory.
2424: (8)                                         ``a.view(ndarray_subclass)`` or ``a.view(type=ndarray_subclass)`` just
2425: (8)                                         returns an instance of `ndarray_subclass` that looks at the same array
2426: (8)                                         (same shape, dtype, etc.) This does not cause a reinterpretation of
the
2427: (8)                                         memory.
2428: (8)                                         If `fill_value` is not specified, but `dtype` is specified (and is not
2429: (8)                                         an ndarray sub-class), the `fill_value` of the MaskedArray will be
2430: (8)                                         reset. If neither `fill_value` nor `dtype` are specified (or if
2431: (8)                                         `dtype` is an ndarray sub-class), then the fill value is preserved.
2432: (8)                                         Finally, if `fill_value` is specified, but `dtype` is not, the fill
2433: (8)                                         value is set to the specified value.
2434: (8)                                         For ``a.view(some_dtype)``, if ``some_dtype`` has a different number
of
2435: (8)                                         bytes per entry than the previous dtype (for example, converting a
2436: (8)                                         regular array to a structured array), then the behavior of the view
2437: (8)                                         cannot be predicted just from the superficial appearance of ``a``
(shown
2438: (8)                                         by ``print(a)``). It also depends on exactly how ``a`` is stored in
memory. Therefore if ``a`` is C-ordered versus fortran-ordered, versus
2439: (8)
2440: (8)
2441: (8)
2442: (8)
2443: (8)                                         defined as a slice or transpose, etc., the view may give different
results.

-----
```

`numpy.nonzero` :  
 Function operating on ndarrays.

`flatnonzero` :  
 Return indices that are non-zero in the flattened version of the array.

`numpy.ndarray.nonzero` :  
 Equivalent ndarray method.

`count_nonzero` :  
 Counts the number of non-zero elements in the input array.

**Examples**

```

>>> import numpy.ma as ma
>>> x = ma.array(np.eye(3))
>>> x
masked_array(
  data=[[1.,  0.,  0.],
        [0.,  1.,  0.],
        [0.,  0.,  1.]],
  mask=False,
  fill_value=1e+20)
>>> x.nonzero()
(array([0, 1, 2]), array([0, 1, 2]))
Masked elements are ignored.
>>> x[1, 1] = ma.masked
>>> x
masked_array(
  data=[[1.0,  0.0,  0.0],
        [0.0,  --,  0.0],
        [0.0,  0.0,  1.0]],
  mask=[[False, False, False],
        [False, True, False],
        [False, False, False]],
  fill_value=1e+20)
>>> x.nonzero()
(array([0, 2]), array([0, 2]))
Indices can also be grouped by element.
>>> np.transpose(x.nonzero())
array([[0, 0],
       [2, 2]])
A common use for ``nonzero`` is to find the indices of an array, where
a condition is True. Given an array `a`, the condition `a > 3` is a
boolean array and since False is interpreted as 0, ma.nonzero(a > 3)
yields the indices of the `a` where the condition is true.
>>> a = ma.array([[1,2,3],[4,5,6],[7,8,9]])
>>> a > 3
>>> masked_array(
    data=[[False, False, False],
          [ True,  True,  True],
          [ True,  True,  True]],
    mask=False,
    fill_value=True)
>>> ma.nonzero(a > 3)
(array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
The ``nonzero`` method of the condition array can also be called.
>>> (a > 3).nonzero()
(array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
"""

    trace.__doc__ = ndarray.trace.__doc__
def dot(self, b, out=None, strict=False):
    """
    a.dot(b, out=None)
    Masked dot product of two arrays. Note that `out` and `strict` are
    located in different positions than in `ma.dot`. In order to
    maintain compatibility with the functional version, it is
    recommended that the optional arguments be treated as keyword only.
    At some point that may be mandatory.
    .. versionadded:: 1.10.0
    Parameters
    -----
    b : masked_array_like
        Inputs array.
    out : masked_array, optional
        Output argument. This must have the exact kind that would be
        returned if it was not used. In particular, it must have the
        right type, must be C-contiguous, and its dtype must be the
        dtype that would be returned for `ma.dot(a,b)`. This is a
        performance feature. Therefore, if these conditions are not
        met, an exception is raised, instead of attempting to be
        flexible.
    strict : bool, optional
        Whether masked data are propagated (True) or set to 0 (False)
        for the computation. Default is False. Propagating the mask
        means that if a masked value appears in a row or column, the
        whole row or column is considered masked.

def min(self, axis=None, out=None, fill_value=None, keepdims=np._NoValue):
    """
        Return the minimum along a given axis.

    Parameters
    -----
    axis : None or int or tuple of ints, optional
        Axis along which to operate. By default, ``axis`` is None and the
        flattened input is used.
        .. versionadded:: 1.7.0
        If this is a tuple of ints, the minimum is selected over multiple
        axes, instead of a single axis or all the axes as before.
    out : array_like, optional
        Alternative output array in which to place the result. Must be of
        the same shape and buffer length as the expected output.
    fill_value : scalar or None, optional
        Value used to fill in the masked values.
        If None, use the output of `minimum_fill_value` .
    keepdims : bool, optional
        If this is set to True, the axes which are reduced are left
        in the result as dimensions with size one. With this option,
        the result will broadcast correctly against the array.

    Returns
    -----
    amin : array_like
        New array holding the result.
        If ``out`` was specified, ``out`` is returned.

    See Also
    -----
    ma.minimum_fill_value
        Returns the minimum filling value for a given datatype.

    Examples
    -----
    >>> import numpy.ma as ma

           the result will broadcast correctly against the array.

           Returns
           -----
           amax : array_like
           New array holding the result.
           If ``out`` was specified, ``out`` is returned.

See Also
-----
ma.maximum_fill_value
           Returns the maximum filling value for a given datatype.

Examples
-----
>>> import numpy.ma as ma
>>> x = [[-1., 2.5], [4., -2.], [3., 0.]]
>>> mask = [[0, 0], [1, 0], [1, 0]]
>>> masked_x = ma.masked_array(x, mask)

        else:
            if out.dtype.kind in 'biu':
                errmsg = "Masked data information would be lost in one or
                           " location."
                raise MaskError(errmsg)
            np.copyto(out, np.nan, where=newmask)
        return out
    def ptp(self, axis=None, out=None, fill_value=None, keepdims=False):
        """
        Return (maximum - minimum) along the given dimension
        (i.e. peak-to-peak value).
        .. warning::
            `ptp` preserves the data type of the array. This means the
            return value for an input of signed integers with n bits
            (e.g. `np.int8`, `np.int16`, etc) is also a signed integer
            with n bits. In that case, peak-to-peak values greater than
            ``2**({n}-1`` will be returned as negative values. An example
            with a work-around is shown below.

        Parameters
        -----
        axis : {None, int}, optional
            Axis along which to find the peaks. If None (default) the
            flattened array is used.
        out : {None, array_like}, optional
            Alternative output array in which to place the result. It must
            have the same shape and buffer length as the expected output
            but the type will be cast if necessary.
        fill_value : scalar or None, optional
            Value used to fill in the masked values.
        keepdims : bool, optional
            If this is set to True, the axes which are reduced are left
            in the result as dimensions with size one. With this option,
            the result will broadcast correctly against the array.

        Returns
        -----
        ptp : ndarray.
            A new array holding the result, unless ``out`` was
            specified, in which case a reference to ``out`` is returned.

        Examples
        -----
        >>> x = np.ma.MaskedArray([[4, 9, 2, 10],
           ...                      [6, 9, 7, 12]])
        >>> x.ptp(axis=1)
        masked_array(data=[8, 6],
                     mask=False,
                     fill_value=999999)
        >>> x.ptp(axis=0)
        masked_array(data=[2, 0, 5, 2],
                     mask=False,
                     fill_value=999999)
        >>> x.ptp()
        10
        This example shows that a negative value can be returned when
        the input is an array of signed integers.
        >>> y = np.ma.MaskedArray([[1, 127],
           ...                      [0, 127],
           ...                      [-1, 127],
           ...                      [-2, 127]], dtype=np.int8)
        >>> y.ptp(axis=1)
        masked_array(data=[ 126,  127, -128, -127],
                     mask=False,
                     fill_value=999999,
                     dtype=int8)
        A work-around is to use the `view()` method to view the result as
        unsigned integers with the same bit width:
        >>> y.ptp(axis=1).view(np.uint8)
        masked_array(data=[126, 127, 128, 129],
                     mask=False,

            """
            Save a masked array to a file in binary format.
            .. warning::
                This function is not implemented yet.
            Raises
            -----
            NotImplementedError
                When `tofile` is called.
            """
            raise NotImplementedError("MaskedArray.tofile() not implemented yet.")

    def toflex(self):
        """
        Transforms a masked array into a flexible-type array.
        The flexible type array that is returned will have two fields:
        * the ``_data`` field stores the ``_data`` part of the array.
        * the ``_mask`` field stores the ``_mask`` part of the array.
        Parameters
        -----
        None
        Returns
        -----
        record : ndarray
            A new flexible-type `ndarray` with two fields: the first element
            containing a value, the second element containing the
            mask boolean. The returned record shape matches self.shape.

    Notes
    -----
    A side-effect of transforming a masked array into a flexible `ndarray`
    is
    that meta information (``fill_value``, ...) will be lost.

    Examples
    -----
    >>> x = np.ma.array([[1,2,3],[4,5,6],[7,8,9]], mask=[0] + [1,0]*4)
    >>> x
    masked_array(
        data=[[1, --, 3],
              [--, 5, --],
              [7, --, 9]],
        mask=[[False, True, False],
              [True, False, True],
              [False, True, False]],
        fill_value=999999)
    >>> x.toflex()
    array([(1, False), (2, True), (3, False)],
          [(4, True), (5, False), (6, True)],
          [(7, False), (8, True), (9, False)]],

5798: (4)               """
5799: (4)               Calculate the n-th discrete difference along the given axis.
5800: (4)               The first difference is given by ``out[i] = a[i+1] - a[i]`` along
5801: (4)               the given axis, higher differences are calculated by using `diff`
5802: (4)               recursively.
5803: (4)               Preserves the input mask.

```

```

5804: (4)          Parameters
5805: (4)          -----
5806: (4)          a : array_like
5807: (8)          Input array
5808: (4)          n : int, optional
5809: (8)          The number of times values are differenced. If zero, the input
5810: (8)          is returned as-is.
5811: (4)          axis : int, optional
5812: (8)          The axis along which the difference is taken, default is the
5813: (8)          last axis.
5814: (4)          prepend, append : array_like, optional
5815: (8)          Values to prepend or append to `a` along axis prior to
5816: (8)          performing the difference. Scalar values are expanded to
5817: (8)          arrays with length 1 in the direction of axis and the shape
5818: (8)          of the input array in along all other axes. Otherwise the
5819: (8)          dimension and shape must match `a` except along axis.
5820: (4)          Returns
5821: (4)          -----
5822: (4)          diff : MaskedArray
5823: (8)          The n-th differences. The shape of the output is the same as `a`
5824: (8)          except along `axis` where the dimension is smaller by `n`. The
5825: (8)          type of the output is the same as the type of the difference
5826: (8)          between any two elements of `a`. This is the same as the type of
5827: (8)          `a` in most cases. A notable exception is `datetime64`, which
5828: (8)          results in a `timedelta64` output array.
5829: (4)          See Also
5830: (4)          -----
5831: (4)          numpy.diff : Equivalent function in the top-level NumPy module.
5832: (4)          Notes
5833: (4)          -----
5834: (4)          Type is preserved for boolean arrays, so the result will contain
5835: (4)          `False` when consecutive elements are the same and `True` when they
5836: (4)          differ.
5837: (4)          For unsigned integer arrays, the results will also be unsigned. This
5838: (4)          should not be surprising, as the result is consistent with
5839: (4)          calculating the difference directly:
5840: (4)          >>> u8_arr = np.array([1, 0], dtype=np.uint8)
5841: (4)          >>> np.ma.diff(u8_arr)
5842: (4)          masked_array(data=[255],
5843: (17)              mask=False,
5844: (11)              fill_value=999999,
5845: (16)              dtype=uint8)
5846: (4)          >>> u8_arr[1,...] - u8_arr[0,...]
5847: (4)          255
5848: (4)          If this is not desirable, then the array should be cast to a larger
5849: (4)          integer type first:
5850: (4)          >>> i16_arr = u8_arr.astype(np.int16)
5851: (4)          >>> np.ma.diff(i16_arr)
5852: (4)          masked_array(data=[-1],

def round_(a, decimals=0, out=None):
"""
Return a copy of a, rounded to 'decimals' places.
When 'decimals' is negative, it specifies the number of positions
to the left of the decimal point. The real and imaginary parts of
complex numbers are rounded separately. Nothing is done if the
array is not of float type and 'decimals' is greater than or equal
to 0.

Parameters
-----
decimals : int
    Number of decimals to round to. May be negative.
out : array_like
    Existing array to use for output.
    If not given, returns a default copy of a.

Notes
-----
If out is given and does not have a mask attribute, the mask of a
is lost!

Examples
-----
>>> import numpy.ma as ma
>>> x = [11.2, -3.973, 0.801, -1.41]
>>> mask = [0, 0, 0, 1]
>>> masked_x = ma.masked_array(x, mask)

6102: (8)         a._mask |= m.any(axis=ax, keepdims=True)
6103: (4)     return a
6104: (0) def dot(a, b, strict=False, out=None):
6105: (4) """
6106: (4)     Return the dot product of two arrays.
6107: (4)     This function is the equivalent of `numpy.dot` that takes masked values
6108: (4)     into account. Note that `strict` and `out` are in different position
6109: (4)     than in the method version. In order to maintain compatibility with the
6110: (4)     corresponding method, it is recommended that the optional arguments be
6111: (4)     treated as keyword only. At some point that may be mandatory.
6112: (4)     Parameters
6113: (4)     -----
6114: (4)     a, b : masked_array_like
6115: (8)         Inputs arrays.
6116: (4)     strict : bool, optional
6117: (8)         Whether masked data are propagated (True) or set to 0 (False) for
6118: (8)         the computation. Default is False. Propagating the mask means that
6119: (8)         if a masked value appears in a row or column, the whole row or
6120: (8)         column is considered masked.
6121: (4)     out : masked_array, optional
6122: (8)         Output argument. This must have the exact kind that would be returned
6123: (8)         if it was not used. In particular, it must have the right type, must
be
6124: (8)         C-contiguous, and its dtype must be the dtype that would be returned
6125: (8)         for `dot(a,b)`. This is a performance feature. Therefore, if these
6126: (8)         conditions are not met, an exception is raised, instead of attempting
6127: (8)         to be flexible.

        """
        Build a masked array from a suitable flexible-type array.
        The input array has to have a data-type with ``_data`` and ``_mask``
        fields. This type of array is output by `MaskedArray.toflex`.
        Parameters
        -----
        fxarray : ndarray
            The structured input array, containing ``_data`` and ``_mask`` fields.
            If present, other fields are discarded.
        Returns
        -----
        result : MaskedArray
            The constructed masked array.
        See Also
        -----
        MaskedArray.toflex : Build a flexible-type array from a masked array.
        Examples
        -----
        >>> x = np.ma.array(np.arange(9).reshape(3, 3), mask=[0] + [1, 0] * 4)
        >>> rec = x.toflex()
        >>> rec
        array([[(0, False), (1, True), (2, False)],
               [(3, True), (4, False), (5, True)],
               [(6, False), (7, True), (8, False)]],
              dtype=[('_data', '<i8'), ('_mask', '?')])
        >>> x2 = np.ma.fromflex(rec)
        >>> x2
        masked_array(
            data=[[0, --, 2],
                  [--, 4, --],
                  [6, --, 8]],
            mask=[[False, True, False],
                  [True, False, True],
                  [False, True, False]],
            fill_value=999999)
        Extra fields can be present in the structured array but are discarded:
        >>> dt = [('data', '<i4'), ('_mask', '|b1'), ('field3', '<f4')]
        >>> rec2 = np.zeros((2, 2), dtype=dt)
        >>> rec2
        array([[ (0, False, 0.), (0, False, 0.)],
               [(0, False, 0.), (0, False, 0.)]],
              dtype=[('_data', '<i4'), ('_mask', '?'), ('field3', '<f4')])
        >>> y = np.ma.fromflex(rec2)
        >>> y
        masked_array(
            data=[[0, 0],
                  [0, 0]],
            mask=[[False, False],
                  [False, False]],

def append(a, b, axis=None):
    """Append values to the end of an array.
    .. versionadded:: 1.9.0
    Parameters
    -----
    a : array_like
        Values are appended to a copy of this array.
    b : array_like
        These values are appended to a copy of `a`. It must be of the
        correct shape (the same shape as `a`, excluding `axis`). If `axis`
        is not specified, `b` can be any shape and will be flattened
        before use.
    axis : int, optional
        The axis along which `v` are appended. If `axis` is not given,
        both `a` and `b` are flattened before use.
    Returns
    -----
    append : MaskedArray
        A copy of `a` with `b` appended to `axis`. Note that `append`
        does not occur in-place: a new array is allocated and filled. If
        `axis` is None, the result is a flattened array.

        Empty masked array with the properties of an existing array.
        Return an empty masked array of the same shape and dtype as
        the array `arr`, where all the data are masked.
        Parameters
        -----
        arr : ndarray
            An array describing the shape and dtype of the required MaskedArray.
        Returns
        -----
        a : MaskedArray
            A masked array with all data masked.
        Raises
        -----
        AttributeError
            If `arr` doesn't have a shape attribute (i.e. not an ndarray)
        See Also
        -----
        masked_all : Empty masked array with all elements masked.
        Examples
        -----
        >>> import numpy.ma as ma
        >>> arr = np.zeros((2, 3), dtype=np.float32)
        >>> arr
        array([[0., 0., 0.],

def cov(x, y=None, rowvar=True, bias=False, allow_masked=True, ddof=None):
"""
Estimate the covariance matrix.
Except for the handling of missing data this function does the same as
`numpy.cov`. For more details and examples, see `numpy.cov`.
By default, masked values are recognized as such. If `x` and `y` have the
same shape, a common mask is allocated: if ``x[i,j]`` is masked, then
``y[i,j]`` will also be masked.
Setting `allow_masked` to False will raise an exception if values are
missing in either of the input arrays.
Parameters
-----
x : array_like
    A 1-D or 2-D array containing multiple variables and observations.
    Each row of `x` represents a variable, and each column a single
    observation of all those variables. Also see `rowvar` below.
y : array_like, optional
    An additional set of variables and observations. `y` has the same
    shape as `x`.
rowvar : bool, optional
    If `rowvar` is True (default), then each row represents a
    variable, with observations in the columns. Otherwise, the
    is transposed: each column represents a variable, while the rows
    contain observations.
bias : bool, optional
    Default normalization (False) is by ``N-1``, where ``N`` is the
    number of observations given (unbiased estimate). If `bias` is True,
    then normalization is by ``N``. This keyword can be overridden by
    the keyword ``ddof`` in numpy versions >= 1.5.
allow_masked : bool, optional
    If True, masked values are propagated pair-wise: if a value is masked
    in `x`, the corresponding value is masked in `y`.
    If False, raises a `ValueError` exception when some values are
missing.
ddof : {None, int}, optional
    If not ``None`` normalization is by ``N - ddof``, where ``N`` is
    the number of observations; this overrides the value implied by
    ``bias``. The default value is ``None``.
.. versionadded:: 1.5
Raises
-----
ValueError
    Raised if some values are missing and `allow_masked` is False.

## File 266 - \_\_init\_\_.py:

```

1: (0)      """
2: (0)      =====
3: (0)      Masked Arrays
4: (0)      =====
5: (0)      Arrays sometimes contain invalid or missing data. When doing operations
6: (0)      on such arrays, we wish to suppress invalid values, which is the purpose
masked
7: (0)      arrays fulfill (an example of typical use is given below).
8: (0)      For example, examine the following array:
9: (0)      >>> x = np.array([2, 1, 3, np.nan, 5, 2, 3, np.nan])
10: (0)      When we try to calculate the mean of the data, the result is undetermined:
11: (0)      >>> np.mean(x)
12: (0)      nan
13: (0)      The mean is calculated using roughly ``np.sum(x)/len(x)``, but since
14: (0)      any number added to ``NaN`` [1]_ produces ``NaN``, this doesn't work. Enter
15: (0)      masked arrays:
16: (0)      >>> m = np.ma.masked_array(x, np.isnan(x))
17: (0)      >>> m
18: (0)      masked_array(data = [2.0 1.0 3.0 -- 5.0 2.0 3.0 --],
19: (6)          mask = [False False False  True False False  True],
20: (6)          fill_value=1e+20)
21: (0)      Here, we construct a masked array that suppress all ``NaN`` values. We
22: (0)      may now proceed to calculate the mean of the other values:
23: (0)      >>> np.mean(m)
24: (0)      2.6666666666666665
25: (0)      .. [1] Not-a-Number, a floating point value that is the result of an
26: (7)          invalid operation.

64: (0) See also -----
65: (0)
66: (0) `numpy.polynomial`_
67: (0) Notes -----
68: (0)
69: (0) The implementations of multiplication, division, integration, and
70: (0) differentiation use the algebraic identities [1]_:
71: (0) .. math::
72: (4)    $T_n(x) = \frac{z^n + z^{-n}}{2}$ 
73: (4)    $z \frac{dx}{dz} = \frac{z - z^{-1}}{2}$ .
74: (0) where
75: (0)   .. math:: x = \frac{z + z^{-1}}{2}.
76: (0) These identities allow a Chebyshev series to be expressed as a finite,
77: (0) symmetric Laurent series. In this module, this sort of Laurent series
78: (0) is referred to as a "z-series."

```

```

802: (4) Note that the result of each integration is *multiplied* by `scl`.
803: (4) Why is this important to note? Say one is making a linear change of
804: (4) variable :math:`u = ax + b` in an integral relative to `x`. Then
805: (4) :math:`dx = du/a`, so one will need to set `scl` equal to
806: (4) :math:`1/a` - perhaps not what one would have first thought.
807: (4) Also note that, in general, the result of integrating a C-series needs
808: (4) to be "reprojected" onto the C-series basis set. Thus, typically,
809: (4) the result of this function is "unintuitive," albeit correct; see

868: (4) If `c` is of length `n + 1`, this function returns the value:
.. math:: p(x) = c_0 * T_0(x) + c_1 * T_1(x) + \dots + c_n * T_n(x)

```

```

870: (4) The parameter `x` is converted to an array only if it is a tuple or a
871: (4) list, otherwise it is treated as a scalar. In either case, either `x`
872: (4) or its elements must support multiplication and addition both with
873: (4) themselves and with the elements of `c`.
874: (4) If `c` is a 1-D array, then `p(x)` will have the same shape as `x`. If
875: (4) `c` is multidimensional, then the shape of the result depends on the
876: (4) value of `tensor`. If `tensor` is true the shape will be c.shape[1:] +
877: (4) x.shape. If `tensor` is false the shape will be c.shape[1:].
878: (4) Note that scalars have shape (,).
879: (4) Trailing zeros in the coefficients will be used in the evaluation, so
880: (4) they should be avoided if efficiency is a concern.
881: (4) Parameters
882: (4) -----
883: (4) x : array_like, compatible object
884: (8) If `x` is a list or tuple, it is converted to an ndarray, otherwise
885: (8) it is left unchanged and treated as a scalar. In either case, `x`
886: (8) or its elements must support addition and multiplication with
887: (8) themselves and with the elements of `c`.
888: (4) c : array_like
889: (8) Array of coefficients ordered so that the coefficients for terms of
890: (8) degree n are contained in c[n]. If `c` is multidimensional the
891: (8) remaining indices enumerate multiple polynomials. In the two
892: (8) dimensional case the coefficients may be thought of as stored in
893: (8) the columns of `c`.
894: (4) tensor : boolean, optional
895: (8) If True, the shape of the coefficient array is extended with ones
896: (8) on the right, one for each dimension of `x`. Scalars have dimension 0
897: (8) for this action. The result is that every column of coefficients in
898: (8) `c` is evaluated for every element of `x`. If False, `x` is broadcast
899: (8) over the columns of `c` for the evaluation. This keyword is useful
900: (8) when `c` is multidimensional. The default value is True.

"""  

    return pu._gridnd(chebval, c, x, y)  

def chebval3d(x, y, z, c):  

    """  

        Evaluate a 3-D Chebyshev series at points (x, y, z).  

        This function returns the values:  

        .. math:: p(x,y,z) = \sum_{i,j,k} c_{i,j,k} * T_i(x) * T_j(y) * T_k(z)  

        The parameters `x`, `y`, and `z` are converted to arrays only if  

        they are tuples or a lists, otherwise they are treated as a scalars and  

        they must have the same shape after conversion. In either case, either  

        `x`, `y`, and `z` or their elements must support multiplication and  

        addition both with themselves and with the elements of `c`.  

        If `c` has fewer than 3 dimensions, ones are implicitly appended to its  

        shape to make it 3-D. The shape of the result will be c.shape[3:] +  

        x.shape.  

    Parameters  

    -----  

    x, y, z : array_like, compatible object  

        The three dimensional series is evaluated at the points  

        `(x, y, z)`, where `x`, `y`, and `z` must have the same shape. If  

        any of `x`, `y`, or `z` is a list or tuple, it is first converted  

        to an ndarray, otherwise it is left unchanged and if it isn't an  

        ndarray it is treated as a scalar.  

    c : array_like  

        Array of coefficients ordered so that the coefficient of the term of  

        multi-degree i,j,k is contained in `c[i,j,k]`. If `c` has dimension  

        greater than 3 the remaining indices enumerate multiple sets of  

        coefficients.  

    Returns  

    -----  

    values : ndarray, compatible object  

        The values of the multidimensional polynomial on points formed with  

        triples of corresponding values from `x`, `y`, and `z`.  

    See Also  

    -----  

    chebval, chebval2d, chebgrid2d, chebgrid3d

1286: (4) numpy.linalg.lstsq : Computes a least-squares fit from the matrix.
1287: (4) scipy.interpolate.UnivariateSpline : Computes spline fits.
1288: (4) Notes
1289: (4)
1290: (4) -----
1291: (4) The solution is the coefficients of the Chebyshev series `p` that
1292: (4) minimizes the sum of the weighted squared errors
1293: (4) .. math:: E = \sum_j w_j^2 * |y_j - p(x_j)|^2,
1294: (4) where :math:`w_j` are the weights. This problem is solved by setting up
1295: (4) as the (typically) overdetermined matrix equation
1296: (4) .. math:: V(x) * c = w * y,
1297: (4) where `V` is the weighted pseudo Vandermonde matrix of `x`, `c` are the
1298: (4) coefficients to be solved for, `w` are the weights, and `y` are the
1299: (4) observed values. This equation is then solved using the singular value
1300: (4) decomposition of `V`.
1301: (4) If some of the singular values of `V` are so small that they are
1302: (4) neglected, then a `RankWarning` will be issued. This means that the
1303: (4) coefficient values may be poorly determined. Using a lower order fit
1304: (4) will usually get rid of the warning. The `rcond` parameter can also be
1305: (4) set to a value smaller than its default, but the resulting fit may be
1306: (4) spurious and have large contributions from roundoff error.
1307: (4) Fits using Chebyshev series are usually better conditioned than fits
1308: (4) using power series, but much can depend on the distribution of the
1309: (4) sample points and the smoothness of the data. If the quality of the fit
1310: (4) is inadequate splines may be a good alternative.

coef : ndarray, shape (deg + 1,) Chebyshev coefficients of the interpolating series ordered from low to
high.
Examples
-----
>>> import numpy.polynomial.chebyshev as C
>>> C.chebfromfunction(lambda x: np.tanh(x) + 0.5, 8)
array([ 5.00000000e-01,  8.11675684e-01, -9.86864911e-17,
       -5.42457905e-02, -2.71387850e-16,  4.51658839e-03,
       2.46716228e-17, -3.79694221e-04, -3.26899002e-16])

Notes
-----
The Chebyshev polynomials used in the interpolation are orthogonal when
sampled at the Chebyshev points of the first kind. If it is desired to
constrain some of the coefficients they can simply be set to the desired
value after the interpolation, no new interpolation or fit is needed. This
is especially useful if it is known apriori that some of coefficients are
zero. For instance, if the function is even then the coefficients of the
terms of odd degree in the result can be set to zero.

572: (4) Raises
573: (4)
574: (4) ValueError
575: (8)     If ``m < 0``, ``len(k) > m``, ``np.ndim(lbnd) != 0``, or
576: (8)     ``np.ndim(scl) != 0``.
577: (4) See Also
578: (4)
579: (4) hermder
580: (4) Notes
581: (4)
582: (4) Note that the result of each integration is *multiplied* by `scl`.
583: (4) Why is this important to note? Say one is making a linear change of
584: (4) variable :math:`u = ax + b` in an integral relative to `x`. Then
585: (4) :math:`dx = du/a`, so one will need to set `scl` equal to
586: (4) :math:`1/a` - perhaps not what one would have first thought.
587: (4) Also note that, in general, the result of integrating a C-series needs
588: (4) to be "reprojected" onto the C-series basis set. Thus, typically,
589: (4) the result of this function is "unintuitive," albeit correct; see
590: (4) Examples section below.
591: (4) Examples
592: (4)
593: (4) >>> from numpy.polynomial.hermite import hermint

637: (12)                     c = tmp
638: (4)             c = np.moveaxis(c, 0, iaxis)
639: (4)             return c
640: (0)             def hermval(x, c, tensor=True):
641: (4)                 """
642: (4)                 Evaluate an Hermite series at points x.
643: (4)                 If `c` is of length `n + 1`, this function returns the value:
644: (4)                 .. math:: p(x) = c_0 * H_0(x) + c_1 * H_1(x) + \dots + c_n * H_n(x)
645: (4)                 The parameter `x` is converted to an array only if it is a tuple or a
646: (4)                 list, otherwise it is treated as a scalar. In either case, either `x`
647: (4)                 or its elements must support multiplication and addition both with
648: (4)                 themselves and with the elements of `c`.
649: (4)                 If `c` is a 1-D array, then `p(x)` will have the same shape as `x`. If
650: (4)                 `c` is multidimensional, then the shape of the result depends on the
651: (4)                 value of `tensor`. If `tensor` is true the shape will be c.shape[1:] +
652: (4)                 x.shape. If `tensor` is false the shape will be c.shape[1:].
653: (4)                 Note that scalars have shape ().
654: (4)                 Trailing zeros in the coefficients will be used in the evaluation, so
655: (4)                 they should be avoided if efficiency is a concern.
656: (4)                 Parameters
657: (4)                 -----
658: (4)                 x : array_like, compatible object
659: (8)                     If `x` is a list or tuple, it is converted to an ndarray, otherwise
660: (8)                     it is left unchanged and treated as a scalar. In either case, `x`
661: (8)                     or its elements must support addition and multiplication with
662: (8)                     themselves and with the elements of `c`.
663: (4)                 c : array_like
664: (8)                     Array of coefficients ordered so that the coefficients for terms of
665: (8)                     degree n are contained in c[n]. If `c` is multidimensional the
666: (8)                     remaining indices enumerate multiple polynomials. In the two
667: (8)                     dimensional case the coefficients may be thought of as stored in
668: (8)                     the columns of `c`.
669: (4)                 tensor : boolean, optional
670: (8)                     If True, the shape of the coefficient array is extended with ones
671: (8)                     on the right, one for each dimension of `x`. Scalars have dimension 0
672: (8)                     for this action. The result is that every column of coefficients in
673: (8)                     `c` is evaluated for every element of `x`. If False, `x` is broadcast
674: (8)                     over the columns of `c` for the evaluation. This keyword is useful
675: (8)                     when `c` is multidimensional. The default value is True.

-----  

x : array_like, shape (M,)  

    x-coordinates of the M sample points ``(x[i], y[i])``.  

y : array_like, shape (M,) or (M, K)  

    y-coordinates of the sample points. Several data sets of sample  

    points sharing the same x-coordinates can be fitted at once by  

    passing in a 2D-array that contains one dataset per column.  

deg : int or 1-D array_like  

    Degree(s) of the fitting polynomials. If `deg` is a single integer  

    all terms up to and including the `deg`'th term are included in the  

    fit. For NumPy versions >= 1.11.0 a list of integers specifying the  

    degrees of the terms to include may be used instead.  

rcond : float, optional  

    Relative condition number of the fit. Singular values smaller than  

    this relative to the largest singular value will be ignored. The  

    default value is len(x)*eps, where eps is the relative precision of  

    the float type, about 2e-16 in most cases.  

full : bool, optional  

    Switch determining nature of return value. When it is False (the  

    default) just the coefficients are returned, when True diagnostic  

    information from the singular value decomposition is also returned.  

w : array_like, shape (`M`), optional  

    Weights. If not None, the weight ``w[i]`` applies to the unsquared  

    residual ``y[i] - y_hat[i]`` at ``x[i]``. Ideally the weights are  

    chosen so that the errors of the products ``w[i]*y[i]`` all have the  

    same variance. When using inverse-variance weighting, use  

    ``w[i] = 1/sigma(y[i])``. The default value is None.  

Returns  

-----  

coef : ndarray, shape (M,) or (M, K)  

    Hermite coefficients ordered from low to high. If `y` was 2-D,  

    the coefficients for the data in column k of `y` are in column  

    `k`.  

[residuals, rank, singular_values, rcond] : list  

    These values are only returned if ``full == True``  

    - residuals -- sum of squared residuals of the least squares fit  

    - rank -- the numerical rank of the scaled Vandermonde matrix  

    - singular_values -- singular values of the scaled Vandermonde matrix  

    - rcond -- value of `rcond`.  

    For more details, see `numpy.linalg.lstsq`.  

Warns  

-----  

RankWarning  

    The rank of the coefficient matrix in the least-squares fit is  

    deficient. The warning is only raised if ``full == False``. The  

    warnings can be turned off by  

    >>> import warnings  

    >>> warnings.simplefilter('ignore', np.RankWarning)

The solution is the coefficients of the Hermite series `p` that  

minimizes the sum of the weighted squared errors  

.. math:: E = \sum_j w_j^2 * |y_j - p(x_j)|^2,  

where the :math:`w_j` are the weights. This problem is solved by  

setting up the (typically) overdetermined matrix equation  

.. math:: V(x) * c = w * y,  

where `V` is the weighted pseudo Vandermonde matrix of `x`, `c` are the

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1090: (4) coefficients to be solved for, `w` are the weights, `y` are the
1091: (4) observed values. This equation is then solved using the singular value
1092: (4) decomposition of `V`.
1093: (4) If some of the singular values of `V` are so small that they are
1094: (4) neglected, then a `RankWarning` will be issued. This means that the
1095: (4) coefficient values may be poorly determined. Using a lower order fit
1096: (4) will usually get rid of the warning. The `rcond` parameter can also be
1097: (4) set to a value smaller than its default, but the resulting fit may be
1098: (4) spurious and have large contributions from roundoff error.
1099: (4) Fits using Hermite series are probably most useful when the data can be
1100: (4) approximated by ``sqrt(w(x)) * p(x)``, where `w(x)` is the Hermite
1101: (4) weight. In that case the weight ``sqrt(w(x[i]))`` should be used
1102: (4) together with data values ``y[i]/sqrt(w(x[i]))``. The weight function is
1103: (4) available as `hermweight`.
