(12)                        G.add_edge(new_node, last_generation_edges[j][0])
(12)                        G.add_edge(new_node, last_generation_edges[j][1])
(12)                        new_node += 1
(4)                 return G
(0)             @nx._dispatchable(graphs=None, returns_graph=True)
(0)             @nodes_or_number(0)
(0)             def empty_graph(n=0, create_using=None, default=Graph):
(4)                 """Returns the empty graph with n nodes and zero edges.
(4)                 .. plot::
(8)                     >>> nx.draw(nx.empty_graph(5))
(4)                 Parameters
(4)                 ----------
(4)                 n : int or iterable container of nodes (default = 0)
(8)                     If n is an integer, nodes are from `range(n)`.
(8)                     If n is a container of nodes, those nodes appear in the graph.
(4)                 create_using : Graph Instance, Constructor or None
(8)                     Indicator of type of graph to return.
(8)                     If a Graph-type instance, then clear and use it.
(8)                     If None, use the `default` constructor.
(8)                     If a constructor, call it to create an empty graph.
(4)                 default : Graph constructor (optional, default = nx.Graph)
(8)                     The constructor to use if create_using is None.
(8)                     If None, then nx.Graph is used.
(8)                     This is used when passing an unknown `create_using` value
(8)                     through your home-grown function to `empty_graph` and
(8)                     you want a default constructor other than nx.Graph.
(4)                 Examples
(4)                 --------
(4)                 >>> G = nx.empty_graph(10)
(4)                 >>> G.number_of_nodes()
(4)                 10
(4)                 >>> G.number_of_edges()
(4)                 0
(4)                 >>> G = nx.empty_graph("ABC")
(4)                 >>> G.number_of_nodes()
(4)                 3
(4)                 >>> sorted(G)
(4)                 ['A', 'B', 'C']
(4)                 Notes
(4)                 -----
(4)                 The variable create_using should be a Graph Constructor or a
(4)                 "graph"-like object. Constructors, e.g. `nx.Graph` or `nx.MultiGraph`
(4)                 will be used to create the returned graph. "graph"-like objects
(4)                 will be cleared (nodes and edges will be removed) and refitted as
(4)                 an empty "graph" with nodes specified in n. This capability
(4)                 is useful for specifying the class-nature of the resulting empty
```

```
458: (4)                "graph" (i.e. Graph, DiGraph, MyWeirdGraphClass, etc.).
459: (4)                The variable create_using has three main uses:
460: (4)                Firstly, the variable create_using can be used to create an
461: (4)                empty digraph, multigraph, etc.  For example,
462: (4)                >>> n = 10
463: (4)                >>> G = nx.empty_graph(n, create_using=nx.DiGraph)
464: (4)                will create an empty digraph on n nodes.
465: (4)                Secondly, one can pass an existing graph (digraph, multigraph,
466: (4)                etc.) via create_using. For example, if G is an existing graph
467: (4)                (resp. digraph, multigraph, etc.), then empty_graph(n, create_using=G)
468: (4)                will empty G (i.e. delete all nodes and edges using G.clear())
469: (4)                and then add n nodes and zero edges, and return the modified graph.
470: (4)                Thirdly, when constructing your home-grown graph creation function
471: (4)                you can use empty_graph to construct the graph by passing a user
472: (4)                defined create_using to empty_graph. In this case, if you want the
473: (4)                default constructor to be other than nx.Graph, specify `default`.
474: (4)                >>> def mygraph(n, create_using=None):
475: (4)                ...     G = nx.empty_graph(n, create_using, nx.MultiGraph)
476: (4)                ...     G.add_edges_from([(0, 1), (0, 1)])
477: (4)                ...     return G
478: (4)                >>> G = mygraph(3)
479: (4)                >>> G.is_multigraph()
480: (4)                True
481: (4)                >>> G = mygraph(3, nx.Graph)
482: (4)                >>> G.is_multigraph()
483: (4)                False
484: (4)                See also create_empty_copy(G).
485: (4)                """

(4)             """Returns the complete multipartite graph with the specified subset
sizes.
(4)             .. plot::
(8)                 >>> nx.draw(nx.complete_multipartite_graph(1, 2, 3))
(4)             Parameters
(4)             ----------
(4)             subset_sizes : tuple of integers or tuple of node iterables
(7)                The arguments can either all be integer number of nodes or they
(7)                can all be iterables of nodes. If integers, they represent the
(7)                number of nodes in each subset of the multipartite graph.
(7)                If iterables, each is used to create the nodes for that subset.
(7)                The length of subset_sizes is the number of subsets.
(4)             Returns
(4)             -------
(4)             G : NetworkX Graph
(7)                Returns the complete multipartite graph with the specified subsets.
(7)                For each node, the node attribute 'subset' is an integer
(7)                indicating which subset contains the node.
(4)             Examples
(4)             --------
(4)             Creating a complete tripartite graph, with subsets of one, two, and three
(4)             nodes, respectively.
(8)                 >>> G = nx.complete_multipartite_graph(1, 2, 3)
(8)                 >>> [G.nodes[u]["subset"] for u in G]
(8)                 [0, 1, 1, 2, 2, 2]
(8)                 >>> list(G.edges(0))
(8)                 [(0, 1), (0, 2), (0, 3), (0, 4), (0, 5)]
(8)                 >>> list(G.edges(2))
(8)                 [(2, 0), (2, 3), (2, 4), (2, 5)]
(8)                 >>> list(G.edges(4))
(8)                 [(4, 0), (4, 1), (4, 2)]
(8)                 >>> G = nx.complete_multipartite_graph("a", "bc", "def")
(8)                 >>> [G.nodes[u]["subset"] for u in sorted(G)]
(8)                 [0, 1, 1, 2, 2, 2]
(4)             Notes
(4)             -----
(4)             This function generalizes several other graph builder functions.
(4)             - If no subset sizes are given, this returns the null graph.
(4)             - If a single subset size `n` is given, this returns the empty graph on
(6)               `n` nodes.
(4)             - If two subset sizes `m` and `n` are given, this returns the complete
(6)               bipartite graph on `m + n` nodes.
(4)             - If subset sizes `1` and `n` are given, this returns the star graph on
(6)               `n + 1` nodes.
(4)             See also

(4)                 max_iters=500,
(4)                 seed=None,
(0)             ):
(4)                 r"""Returns the LFR benchmark graph.
(4)                 This algorithm proceeds as follows:
(4)                 1) Find a degree sequence with a power law distribution, and minimum
(7)                    value ``min_degree``, which has approximate average degree
(7)                    ``average_degree``. This is accomplished by either
(7)                    a) specifying ``min_degree`` and not ``average_degree``,
(7)                    b) specifying ``average_degree`` and not ``min_degree``, in which
(10)                      case a suitable minimum degree will be found.
(7)                    ``max_degree`` can also be specified, otherwise it will be set to
(7)                    ``n``. Each node *u* will have $\mu \mathrm{deg}(u)$ edges
(7)                    joining it to nodes in communities other than its own and $(1 -
(7)                    \mu) \mathrm{deg}(u)$ edges joining it to nodes in its own
(7)                    community.
(4)                 2) Generate community sizes according to a power law distribution
(7)                    with exponent ``tau2``. If ``min_community`` and
(7)                    ``max_community`` are not specified they will be selected to be
(7)                    ``min_degree`` and ``max_degree``, respectively.  Community sizes
(7)                    are generated until the sum of their sizes equals ``n``.
(4)                 3) Each node will be randomly assigned a community with the
(7)                    condition that the community is large enough for the node's
(7)                    intra-community degree, $(1 - \mu) \mathrm{deg}(u)$ as
(7)                    described in step 2. If a community grows too large, a random node
(7)                    will be selected for reassignment to a new community, until all
(7)                    nodes have been assigned a community.
(4)                 4) Each node *u* then adds $(1 - \mu) \mathrm{deg}(u)$
(7)                    intra-community edges and $\mu \mathrm{deg}(u)$ inter-community
(7)                    edges.
(4)                 Parameters
(4)                 ----------
(4)                 n : int
(8)                     Number of nodes in the created graph.
(4)                 tau1 : float
(8)                     Power law exponent for the degree distribution of the created
(8)                     graph. This value must be strictly greater than one.
(4)                 tau2 : float
(8)                     Power law exponent for the community size distribution in the
(8)                     created graph. This value must be strictly greater than one.
(4)                 mu : float
(8)                     Fraction of inter-community edges incident to each node. This
(8)                     value must be in the interval [0, 1].
(4)                 average_degree : float
(8)                     Desired average degree of nodes in the created graph. This value
(8)                     must be in the interval [0, *n*]. Exactly one of this and
(8)                     ``min_degree`` must be specified, otherwise a
(8)                     :exc:`NetworkXError` is raised.
(4)                 min_degree : int
(8)                     Minimum degree of nodes in the created graph. This value must be
(8)                     in the interval [0, *n*]. Exactly one of this and
(8)                     ``average_degree`` must be specified, otherwise a
(8)                     :exc:`NetworkXError` is raised.
(4)                 max_degree : int
(8)                     Maximum degree of nodes in the created graph. If not specified,
(8)                     this is set to ``n``, the total number of nodes in the graph.
(4)                 min_community : int
(8)                     Minimum size of communities in the graph. If not specified, this
(8)                     is set to ``min_degree``.
(4)                 max_community : int
(8)                     Maximum size of communities in the graph. If not specified, this
(8)                     is set to ``n``, the total number of nodes in the graph.
(4)                 tol : float
(8)                     Tolerance when comparing floats, specifically when comparing
(8)                     average degree values.
(4)                 max_iters : int
(8)                     Maximum number of iterations to try to create the community sizes,
```

```
    degree distribution, and community affiliations.
seed : integer, random_state, or None (default)
    Indicator of random number generation state.
    See :ref:`Randomness<randomness>`.
Returns
-------
G : NetworkX graph
    The LFR benchmark graph generated according to the specified
    parameters.
    Each node in the graph has a node attribute ``'community'`` that
    stores the community (that is, the set of nodes) that includes
    it.
Raises
------
NetworkXError
    If any of the parameters do not meet their upper and lower bounds:
    - ``tau1`` and ``tau2`` must be strictly greater than 1.
    - ``mu`` must be in [0, 1].
    - ``max_degree`` must be in {1, ..., *n*}.
    - ``min_community`` and ``max_community`` must be in {0, ...,
      *n*}.
    If not exactly one of ``average_degree`` and ``min_degree`` is
    specified.
    If ``min_degree`` is not specified and a suitable ``min_degree``
    cannot be found.
ExceededMaxIterations
    If a valid degree sequence cannot be created within
    ``max_iters`` number of iterations.
    If a valid set of community sizes cannot be created within
    ``max_iters`` number of iterations.
    If a valid community assignment cannot be created within ``10 *
    n * max_iters`` number of iterations.
Examples
--------
Basic usage::
    >>> from networkx.generators.community import LFR_benchmark_graph
    >>> n = 250
    >>> tau1 = 3
    >>> tau2 = 1.5
    >>> mu = 0.1
    >>> G = LFR_benchmark_graph(
    ...     n, tau1, tau2, mu, average_degree=5, min_community=20, seed=10
    ... )
Continuing the example above, you can get the communities from the
node attributes of the graph::
    >>> communities = {frozenset(G.nodes[v]["community"]) for v in G}
Notes
-----
This algorithm differs slightly from the original way it was
presented in [1].
1) Rather than connecting the graph via a configuration model then
   rewiring to match the intra-community and inter-community
   degrees, we do this wiring explicitly at the end, which should be
   equivalent.
2) The code posted on the author's website [2] calculates the random
   power law distributed variables and their average using
   continuous approximations, whereas we use the discrete
   distributions here as both degree and community size are
   discrete.
Though the authors describe the algorithm as quite robust, testing
during development indicates that a somewhat narrower parameter set
is likely to successfully produce a graph. Some suggestions have
been provided in the event of exceptions.

101: (8)                    Indicator of random number generation state.
102: (8)                    See :ref:`Randomness<randomness>`.
103: (4)                Returns
104: (4)                -------
105: (4)                G : MultiGraph
106: (8)                    A graph with the specified degree sequence.
107: (8)                    Nodes are labeled starting at 0 with an index
108: (8)                    corresponding to the position in deg_sequence.
109: (4)                Raises
110: (4)                ------
111: (4)                NetworkXError
112: (8)                    If the degree sequence does not have an even sum.
113: (4)                See Also
114: (4)                --------
115: (4)                is_graphical
116: (4)                Notes
117: (4)                -----
118: (4)                As described by Newman [1]_.
119: (4)                A non-graphical degree sequence (not realizable by some simple
120: (4)                graph) is allowed since this function returns graphs with self
121: (4)                loops and parallel edges.  An exception is raised if the degree
122: (4)                sequence does not have an even sum.
123: (4)                This configuration model construction process can lead to
124: (4)                duplicate edges and loops.  You can remove the self-loops and
125: (4)                parallel edges (see below) which will likely result in a graph
126: (4)                that doesn't have the exact degree sequence specified.
127: (4)                The density of self-loops and parallel edges tends to decrease as
128: (4)                the number of nodes increases. However, typically the number of
129: (4)                self-loops will approach a Poisson distribution with a nonzero mean,
130: (4)                and similarly for the number of parallel edges.  Consider a node
131: (4)                with *k* stubs. The probability of being joined to another stub of
132: (4)                the same node is basically (*k* - *1*) / *N*, where *k* is the
133: (4)                degree and *N* is the number of nodes. So the probability of a
134: (4)                self-loop scales like *c* / *N* for some constant *c*. As *N* grows,
135: (4)                this means we expect *c* self-loops. Similarly for parallel edges.

271: (4)                Examples
272: (4)                --------
273: (4)                >>> z = [10 for i in range(100)]
274: (4)                >>> G = nx.expected_degree_graph(z)
275: (4)                Notes
276: (4)                -----
277: (4)                The nodes have integer labels corresponding to index of expected degrees
278: (4)                input sequence.
279: (4)                The complexity of this algorithm is $\mathcal{O}(n+m)$ where $n$ is the
280: (4)                number of nodes and $m$ is the expected number of edges.
281: (4)                The model in [1]_ includes the possibility of self-loop edges.
282: (4)                Set selfloops=False to produce a graph without self loops.
283: (4)                For finite graphs this model doesn't produce exactly the given
284: (4)                expected degree sequence.  Instead the expected degrees are as
```

```
(4)                 follows.
(4)                 For the case without self loops (selfloops=False),
(4)                 .. math::
(7)                    E[deg(u)] = \sum_{v \ne u} p_{uv}
(16)                            = w_u \left( 1 - \frac{w_u}{\sum_k w_k} \right) .
(4)                 NetworkX uses the standard convention that a self-loop edge counts 2
(4)                 in the degree of a node, so with self loops (selfloops=True),
(4)                 .. math::
(7)                    E[deg(u)] =  \sum_{v \ne u} p_{uv}  + 2 p_{uu}
(16)                            = w_u \left( 1 + \frac{w_u}{\sum_k w_k} \right) .

(4)                 A random `k`-out graph with preferential attachment is a
(4)                 multidigraph generated by the following algorithm.
(4)                 1. Begin with an empty digraph, and initially set each node to have
(7)                    weight `alpha`.
(4)                 2. Choose a node `u` with out-degree less than `k` uniformly at
(7)                    random.
(4)                 3. Choose a node `v` from with probability proportional to its
(7)                    weight.
(4)                 4. Add a directed edge from `u` to `v`, and increase the weight
(7)                    of `v` by one.
(4)                 5. If each node has out-degree `k`, halt, otherwise repeat from
(7)                    step 2.
(4)                 For more information on this model of random graph, see [1].
(4)                 Parameters
(4)                 ----------
(4)                 n : int
(8)                     The number of nodes in the returned graph.
(4)                 k : int
(8)                     The out-degree of each node in the returned graph.
(4)                 alpha : float
(8)                     A positive :class:`float` representing the initial weight of
(8)                     each vertex. A higher number means that in step 3 above, nodes
(8)                     will be chosen more like a true uniformly random sample, and a
(8)                     lower number means that nodes are more likely to be chosen as
(8)                     their in-degree increases. If this parameter is not positive, a
(8)                     :exc:`ValueError` is raised.
(4)                 self_loops : bool
(8)                     If True, self-loops are allowed when generating the graph.
(4)                 seed : integer, random_state, or None (default)
(8)                     Indicator of random number generation state.
(8)                     See :ref:`Randomness<randomness>`.
(4)                 Returns
(4)                 -------
(4)                 :class:`~networkx.classes.MultiDiGraph`
(8)                     A `k`-out-regular multidigraph generated according to the above
(8)                     algorithm.
(4)                 Raises
(4)                 ------
(4)                 ValueError

52: (4)                 vertex `x` to its inverse modulo `p`. This graph is a (mildly explicit)
53: (4)                 3-regular expander [1]_.
54: (4)                 `p` *must* be a prime number.
55: (4)                 Parameters
56: (4)                 ----------
57: (4)                 p : a prime number
58: (8)                     The number of vertices in the graph. This also indicates where the
59: (8)                     chordal edges in the cycle will be created.
```

```
    create_using : NetworkX graph constructor, optional (default=nx.Graph)
       Graph type to create. If graph instance, then cleared before populated.
    Returns
    -------
    G : graph
        The constructed undirected multigraph.
    Raises
    ------
    NetworkXError
        If `create_using` indicates directed or not a multigraph.
    References
    ----------
    .. [1] Theorem 4.4.2 in A. Lubotzky. "Discrete groups, expanding graphs and
           invariant measures", volume 125 of Progress in Mathematics.
           Birkhäuser Verlag, Basel, 1994.
    """
    G = nx.empty_graph(0, create_using, default=nx.MultiGraph)

@nx._dispatchable(graphs=None, returns_graph=True)
def paley_graph(p, create_using=None):
    r"""Returns the Paley $\frac{(p-1)}{2}$ -regular graph on $p$ nodes.
    The returned graph is a graph on $\mathbb{Z}/p\mathbb{Z}$ with edges between $x$ and $y$
    if and only if $x-y$ is a nonzero square in $\mathbb{Z}/p\mathbb{Z}$.
    If $p \equiv 1  \pmod 4$, $-1$ is a square in $\mathbb{Z}/p\mathbb{Z}$ and therefore $x-y$ is a square if and
    only if $y-x$ is also a square, i.e the edges in the Paley graph are symmetric.
    If $p \equiv 3 \pmod 4$, $-1$ is not a square in $\mathbb{Z}/p\mathbb{Z}$ and therefore either $x-y$ or $y-x$
    is a square in $\mathbb{Z}/p\mathbb{Z}$ but not both.
    Note that a more general definition of Paley graphs extends this construction
    to graphs over $q=p^n$ vertices, by using the finite field $F_q$ instead of $\mathbb{Z}/p\mathbb{Z}$.
    This construction requires to compute squares in general finite fields and is
    not what is implemented here (i.e `paley_graph(25)` does not return the true
    Paley graph associated with $5^2$).
    Parameters
    ----------
    p : int, an odd prime number.
    create_using : NetworkX graph constructor, optional (default=nx.Graph)
       Graph type to create. If graph instance, then cleared before populated.
    Returns
    -------
    G : graph
        The constructed directed graph.
    Raises
    ------
    NetworkXError
        If the graph is a multigraph.

    r"""Utility for creating a random regular expander.
    Returns a random $d$-regular graph on $n$ nodes which is an expander
    graph with very good probability.
    Parameters
    ----------
    n : int
      The number of nodes.
    d : int
      The degree of each node.
    create_using : Graph Instance or Constructor
      Indicator of type of graph to return.
      If a Graph-type instance, then clear and use it.
      If a constructor, call it to create an empty graph.
      Use the Graph constructor by default.
    max_tries : int. (default: 100)
      The number of allowed loops when generating each independent cycle
    seed : (default: None)
      Seed used to set random number generation state. See :ref`Randomness<randomness>`.
    Notes
    -----
    The nodes are numbered from $0$ to $n - 1$.
    The graph is generated by taking $d / 2$ random independent cycles.
    Joel Friedman proved that in this model the resulting
    graph is an expander with probability
    $1 - O(n^{-\tau})$ where $\tau = \lceil (\sqrt{d - 1}) / 2 \rceil - 1$. [1]_
    Examples
    --------
    >>> G = nx.maybe_regular_expander(n=200, d=6, seed=8020)
    Returns
    -------
    G : graph
        The constructed undirected graph.
    Raises
    ------
    NetworkXError
        If $d % 2 != 0$ as the degree must be even.
        If $n - 1$ is less than $ 2d $ as the graph is complete at most.
        If max_tries is reached

167: (4)                r"""Returns a soft random geometric graph in the unit cube.
168: (4)                The soft random geometric graph [1] model places `n` nodes uniformly at
169: (4)                random in the unit cube in dimension `dim`. Two nodes of distance, `dist`,
170: (4)                computed by the `p`-Minkowski distance metric are joined by an edge with
171: (4)                probability `p_dist` if the computed distance metric value of the nodes
172: (4)                is at most `radius`, otherwise they are not joined.
173: (4)                Edges within `radius` of each other are determined using a KDTree when
174: (4)                SciPy is available. This reduces the time complexity from :math:`O(n^2)`
175: (4)                to :math:`O(n)`.
176: (4)                Parameters
177: (4)                ----------
178: (4)                n : int or iterable
179: (8)                    Number of nodes or iterable of nodes
180: (4)                radius: float
181: (8)                    Distance threshold value
182: (4)                dim : int, optional
183: (8)                    Dimension of graph
184: (4)                pos : dict, optional
```

```
        A dictionary keyed by node with node positions as values.
    p : float, optional
        Which Minkowski distance metric to use.
        `p` has to meet the condition ``1 <= p <= infinity``.
        If this argument is not specified, the :math:`L^2` metric
        (the Euclidean distance metric), p = 2 is used.
        This should not be confused with the `p` of an Erdős-Rényi random
        graph, which represents probability.
    p_dist : function, optional
        A probability density function computing the probability of
        connecting two nodes that are of distance, dist, computed by the
        Minkowski distance metric. The probability density function, `p_dist`,
        must be any function that takes the metric value as input
        and outputs a single probability value between 0-1. The scipy.stats
        package has many probability distribution functions implemented and
        tools for custom probability distribution definitions [2], and passing
        the .pdf method of scipy.stats distributions can be used here.  If the
        probability function, `p_dist`, is not supplied, the default function
        is an exponential distribution with rate parameter :math:`\lambda=1`.
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
    pos_name : string, default="pos"
        The name of the node attribute which represents the position
        in 2D coordinates of the node in the returned graph.
    Returns
    -------
    Graph
        A soft random geometric graph, undirected and without self-loops.
        Each node has a node attribute ``'pos'`` that stores the
        position of that node in Euclidean space as provided by the
        ``pos`` keyword argument or, if ``pos`` was not provided, as
        generated by this function.
    Examples
    --------
    Default Graph:
    G = nx.soft_random_geometric_graph(50, 0.2)
    Custom Graph:
    Create a soft random geometric graph on 100 uniformly distributed nodes
    where nodes are joined by an edge with probability computed from an
    exponential distribution with rate parameter :math:`\lambda=1` if their
    Euclidean distance is at most 0.2.
    Notes
    -----
    This uses a *k*-d tree to build the graph.
    The `pos` keyword argument can be used to specify node positions so you
    can create an arbitrary distribution and domain for positions.
    For example, to use a 2D Gaussian distribution of node positions with mean
    (0, 0) and standard deviation 2
    The scipy.stats package can be used to define the probability distribution
    with the .pdf method used as `p_dist`.
    ::
    >>> import random
    >>> import math
    >>> n = 100
    >>> pos = {i: (random.gauss(0, 2), random.gauss(0, 2)) for i in range(n)}
    >>> p_dist = lambda dist: math.exp(-dist)
    >>> G = nx.soft_random_geometric_graph(n, 0.2, pos=pos, p_dist=p_dist)

(4)                 *,
(4)                 pos_name="pos",
(4)                 weight_name="weight",
(0)             ):
(4)                 r"""Returns a geographical threshold graph.
(4)                 The geographical threshold graph model places $n$ nodes uniformly at
(4)                 random in a rectangular domain.  Each node $u$ is assigned a weight
(4)                 $w_u$. Two nodes $u$ and $v$ are joined by an edge if
(4)                 .. math::
(7)                    (w_u + w_v)p_{dist}(r) \ge \theta
(4)                 where `r` is the distance between `u` and `v`, `p_dist` is any function of
(4)                 `r`, and :math:`\theta` as the threshold parameter. `p_dist` is used to
(4)                 give weight to the distance between nodes when deciding whether or not
(4)                 they should be connected. The larger `p_dist` is, the more prone nodes
(4)                 separated by `r` are to be connected, and vice versa.
(4)                 Parameters
(4)                 ----------
(4)                 n : int or iterable
(8)                     Number of nodes or iterable of nodes
(4)                 theta: float
(8)                     Threshold value
(4)                 dim : int, optional
(8)                     Dimension of graph
(4)                 pos : dict
(8)                     Node positions as a dictionary of tuples keyed by node.
(4)                 weight : dict
(8)                     Node weights as a dictionary of numbers keyed by node.
(4)                 metric : function
(8)                     A metric on vectors of numbers (represented as lists or
(8)                     tuples). This must be a function that accepts two lists (or
(8)                     tuples) as input and yields a number as output. The function
(8)                     must also satisfy the four requirements of a `metric`_.
(8)                     Specifically, if $d$ is the function and $x$, $y$,
(8)                     and $z$ are vectors in the graph, then $d$ must satisfy
(8)                     1. $d(x, y) \ge 0$,
(8)                     2. $d(x, y) = 0$ if and only if $x = y$,
(8)                     3. $d(x, y) = d(y, x)$,
(8)                     4. $d(x, z) \le d(x, y) + d(y, z)$.
(8)                     If this argument is not specified, the Euclidean distance metric is
(8)                     used.
(8)                     .. _metric: https://en.wikipedia.org/wiki/Metric_%28mathematics%29
(4)                 p_dist : function, optional
(8)                     Any function used to give weight to the distance between nodes when
(8)                     deciding whether or not they should be connected. `p_dist` was
(8)                     originally conceived as a probability density function giving the
(8)                     probability of connecting two nodes that are of metric distance `r`
```

```
            apart. The implementation here allows for more arbitrary definitions
            of `p_dist` that do not need to correspond to valid probability
            density functions. The :mod:`scipy.stats` package has many
            probability density functions implemented and tools for custom
            probability density definitions, and passing the ``.pdf`` method of
            scipy.stats distributions can be used here. If ``p_dist=None``
            (the default), the exponential function :math:`r^{-2}` is used.
        seed : integer, random_state, or None (default)
            Indicator of random number generation state.
            See :ref:`Randomness<randomness>`.
        pos_name : string, default="pos"
            The name of the node attribute which represents the position
            in 2D coordinates of the node in the returned graph.
        weight_name : string, default="weight"
            The name of the node attribute which represents the weight
            of the node in the returned graph.
        Returns
        -------
        Graph
            A random geographic threshold graph, undirected and without
            self-loops.
            Each node has a node attribute ``pos`` that stores the
            position of that node in Euclidean space as provided by the
            ``pos`` keyword argument or, if ``pos`` was not provided, as
            generated by this function. Similarly, each node has a node
            attribute ``weight`` that stores the weight of that node as
            provided or as generated.
        Examples
        --------
        Specify an alternate distance metric using the ``metric`` keyword
        argument. For example, to use the `taxicab metric`_ instead of the
        default `Euclidean metric`_::
            >>> dist = lambda x, y: sum(abs(a - b) for a, b in zip(x, y))
            >>> G = nx.geographical_threshold_graph(10, 0.1, metric=dist)
        .. _taxicab metric: https://en.wikipedia.org/wiki/Taxicab_geometry
        .. _Euclidean metric: https://en.wikipedia.org/wiki/Euclidean_distance
        Notes
        -----
        If weights are not specified they are assigned to nodes by drawing randomly
        from the exponential distribution with rate parameter $\lambda=1$.
        To specify weights from a different distribution, use the `weight` keyword
        argument::
        >>> import random
        >>> n = 20
        >>> w = {i: random.expovariate(5.0) for i in range(n)}
        >>> G = nx.geographical_threshold_graph(20, 50, weight=w)
        If node positions are not specified they are randomly assigned from the
        uniform distribution.

457: (8)                    in 2D coordinates of the node in the returned graph.
```

```
    Returns
    -------
    Graph
        A random Waxman graph, undirected and without self-loops. Each
        node has a node attribute ``'pos'`` that stores the position of
        that node in Euclidean space as generated by this function.
    Examples
    --------
    Specify an alternate distance metric using the ``metric`` keyword
    argument. For example, to use the "`taxicab metric`_" instead of the
    default `Euclidean metric`_::
        >>> dist = lambda x, y: sum(abs(a - b) for a, b in zip(x, y))
        >>> G = nx.waxman_graph(10, 0.5, 0.1, metric=dist)
    .. _taxicab metric: https://en.wikipedia.org/wiki/Taxicab_geometry
    .. _Euclidean metric: https://en.wikipedia.org/wiki/Euclidean_distance
    Notes
    -----
    Starting in NetworkX 2.0 the parameters alpha and beta align with their
    usual roles in the probability distribution. In earlier versions their
    positions in the expression were reversed. Their position in the calling
    sequence reversed as well to minimize backward incompatibility.

    r"""Returns a navigable small-world graph.
    A navigable small-world graph is a directed grid with additional long-range

    connections that are chosen randomly.
      [...] we begin with a set of nodes [...] that are identified with the set

      of lattice points in an $n \times n$ square,
      $\{(i, j): i \in \{1, 2, \ldots, n\}, j \in \{1, 2, \ldots, n\}\}$,
      and we define the *lattice distance* between two nodes $(i, j)$ and
      $(k, l)$ to be the number of "lattice steps" separating them:
      $d((i, j), (k, l)) = |k - i| + |l - j|$.
      For a universal constant $p >= 1$, the node $u$ has a directed edge to
      every other node within lattice distance $p$---these are its *local
      contacts*. For universal constants $q >= 0$ and $r >= 0$ we also
      construct directed edges from $u$ to $q$ other nodes (the *long-range
      contacts*) using independent random trials; the $i$th directed edge from
      $u$ has endpoint $v$ with probability proportional to $[d(u,v)]^{-r}$.
      -- [1]_
    Parameters
    ----------
    n : int
        The length of one side of the lattice; the number of nodes in
        the graph is therefore $n^2$.
```

```
(4)                 p : int
(8)                     The diameter of short range connections. Each node is joined with
every
(8)                     other node within this lattice distance.
(4)                 q : int
(8)                     The number of long-range connections for each node.
(4)                 r : float
(8)                     Exponent for decaying probability of connections.  The probability of
(8)                     connecting to a node at lattice distance $d$ is $1/d^r$.

(0)             ):
(4)                 r"""Returns a thresholded random geometric graph in the unit cube.
(4)                 The thresholded random geometric graph [1] model places `n` nodes
(4)                 uniformly at random in the unit cube of dimensions `dim`. Each node
(4)                 `u` is assigned a weight :math:`w_u`. Two nodes `u` and `v` are
(4)                 joined by an edge if they are within the maximum connection distance,
(4)                 `radius` computed by the `p`-Minkowski distance and the summation of
(4)                 weights :math:`w_u` + :math:`w_v` is greater than or equal
(4)                 to the threshold parameter `theta`.
(4)                 Edges within `radius` of each other are determined using a KDTree when
(4)                 SciPy is available. This reduces the time complexity from :math:`O(n^2)`
(4)                 to :math:`O(n)`.
(4)                 Parameters
(4)                 ----------
```

```
    n : int or iterable
        Number of nodes or iterable of nodes
    radius: float
        Distance threshold value
    theta: float
        Threshold value
    dim : int, optional
        Dimension of graph
    pos : dict, optional
        A dictionary keyed by node with node positions as values.
    weight : dict, optional
        Node weights as a dictionary of numbers keyed by node.
    p : float, optional (default 2)
        Which Minkowski distance metric to use.  `p` has to meet the condition
        ``1 <= p <= infinity``.
        If this argument is not specified, the :math:`L^2` metric
        (the Euclidean distance metric), p = 2 is used.
        This should not be confused with the `p` of an Erdős-Rényi random
        graph, which represents probability.
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
    pos_name : string, default="pos"
        The name of the node attribute which represents the position
        in 2D coordinates of the node in the returned graph.
    weight_name : string, default="weight"
        The name of the node attribute which represents the weight
        of the node in the returned graph.
    Returns
    -------
    Graph
        A thresholded random geographic graph, undirected and without
        self-loops.
        Each node has a node attribute ``'pos'`` that stores the
        position of that node in Euclidean space as provided by the
        ``pos`` keyword argument or, if ``pos`` was not provided, as
        generated by this function. Similarly, each node has a nodethre
        attribute ``'weight'`` that stores the weight of that node as
        provided or as generated.
    Examples
    --------
    Default Graph:
    G = nx.thresholded_random_geometric_graph(50, 0.2, 0.1)
    Custom Graph:
    Create a thresholded random geometric graph on 50 uniformly distributed
    nodes where nodes are joined by an edge if their sum weights drawn from
    a exponential distribution with rate = 5 are >= theta = 0.1 and their
    Euclidean distance is at most 0.2.
    Notes
    -----
    This uses a *k*-d tree to build the graph.
    The `pos` keyword argument can be used to specify node positions so you
    can create an arbitrary distribution and domain for positions.
    For example, to use a 2D Gaussian distribution of node positions with mean
    (0, 0) and standard deviation 2
    If weights are not specified they are assigned to nodes by drawing
randomly
    from the exponential distribution with rate parameter :math:`\lambda=1`.
    To specify weights from a different distribution, use the `weight` keyword
    argument::
    ::
    >>> import random
    >>> import math
    >>> n = 50
    >>> pos = {i: (random.gauss(0, 2), random.gauss(0, 2)) for i in range(n)}
    >>> w = {i: random.expovariate(5.0) for i in range(n)}
    >>> G = nx.thresholded_random_geometric_graph(n, 0.2, 0.1, 2, pos, w)
    References

def geometric_soft_configuration_graph(
    *, beta, n=None, gamma=None, mean_degree=None, kappas=None, seed=None
):
    r"""Returns a random graph from the geometric soft configuration model.
    The $\mathbb{S}^1$ model [1]_ is the geometric soft configuration model
    which is able to explain many fundamental features of real networks such as
    small-world property, heteregenous degree distributions, high level of
    clustering, and self-similarity.
    In the geometric soft configuration model, a node $i$ is assigned two hidden
    variables: a hidden degree $\kappa_i$, quantifying its popularity, influence,
    or importance, and an angular position $\theta_i$ in a circle abstracting the
    similarity space, where angular distances between nodes are a proxy for their
    similarity. Focusing on the angular position, this model is often called
    the $\mathbb{S}^1$ model (a one-dimensional sphere). The circle's radius is
    adjusted to $R = N/2\pi$, where $N$ is the number of nodes, so that the density
    is set to 1 without loss of generality.
    The connection probability between any pair of nodes increases with
    the product of their hidden degrees (i.e., their combined popularities),
    and decreases with the angular distance between the two nodes.
    Specifically, nodes $i$ and $j$ are connected with the probability
    $p_{ij} = \frac{1}{1 + \frac{d_{ij}^\beta}{\left(\mu \kappa_i \kappa_j\right)^{\max(1, \beta)}}}$
    where $d_{ij} = R\Delta\theta_{ij}$ is the arc length of the circle between
    nodes $i$ and $j$ separated by an angular distance $\Delta\theta_{ij}$.
    Parameters $\mu$ and $\beta$ (also called inverse temperature) control the
    average degree and the clustering coefficient, respectively.
    It can be shown [2]_ that the model undergoes a structural phase transition
    at $\beta=1$ so that for $\beta<1$ networks are unclustered in the thermodynamic
    limit (when $N\to \infty$) whereas for $\beta>1$ the ensemble generates
    networks with finite clustering coefficient.
    The $\mathbb{S}^1$ model can be expressed as a purely geometric model
    $\mathbb{H}^2$ in the hyperbolic plane [3]_ by mapping the hidden degree of
    each node into a radial coordinate as
    $r_i = \hat{R} - \frac{2 \max(1, \beta)}{\beta \zeta} \ln \left(\frac{\kappa_i}{\kappa_0}\right)$
    where $\hat{R}$ is the radius of the hyperbolic disk and $\zeta$ is the curvature,
    $\hat{R} = \frac{2}{\zeta} \ln \left(\frac{N}{\pi}\right)
```

```
715: (4)                - \frac{2\max(1, \beta)}{\beta \zeta} \ln (\mu \kappa_0^2)$
716: (4)                The connection probability then reads
717: (4)                $p_{ij} = \frac{1}{1 + \exp\left({\frac{\beta\zeta}{2} (x_{ij} -
\hat{R})}\right)}$
718: (4)                where
719: (4)                $x_{ij} = r_i + r_j + \frac{2}{\zeta} \ln \frac{\Delta\theta_{ij}}{2}$
720: (4)                is a good approximation of the hyperbolic distance between two nodes
separated
721: (4)                by an angular distance $\Delta\theta_{ij}$ with radial coordinates $r_i$
and $r_j$.
722: (4)                For $\beta > 1$, the curvature $\zeta = 1$, for $\beta < 1$, $\zeta =
\beta^{-1}$.

(8)                     Indicator of random number generation state.
(8)                     See :ref:`Randomness<randomness>`.
(4)                 Returns
(4)                 -------
(4)                 G : Graph
(8)                     A graph with the specified joint degree dictionary.
(4)                 Raises
(4)                 ------
(4)                 NetworkXError
(8)                     If *joint_degrees* dictionary is not realizable.
(4)                 Notes
(4)                 -----
(4)                 In each iteration of the "while loop" the algorithm picks two disconnected
(4)                 nodes *v* and *w*, of degree *k* and *l* correspondingly,  for which
(4)                 ``joint_degrees[k][l]`` has not reached its target yet. It then adds
(4)                 edge (*v*, *w*) and increases the number of edges in graph G by one.
(4)                 The intelligence of the algorithm lies in the fact that  it is always
(4)                 possible to add an edge between such disconnected nodes *v* and *w*,
(4)                 even if one or both nodes do not have free stubs. That is made possible by
(4)                 executing a "neighbor switch", an edge rewiring move that releases
(4)                 a free stub while keeping the joint degree of G the same.
(4)                 The algorithm continues for E (number of edges) iterations of
(4)                 the "while loop", at the which point all entries of the given
(4)                 ``joint_degrees[k][l]`` have reached their target values and the
```

373: (4)                    Raises
374: (4)                    ------
375: (4)                    NetworkXError
376: (8)                        If degree_seq and nkk are not realizable as a simple directed graph.
377: (4)                    Notes
378: (4)                    -----
379: (4)                    Similarly to the undirected version:
380: (4)                    In each iteration of the "while loop" the algorithm picks two disconnected
381: (4)                    nodes v and w, of degree k and l correspondingly,  for which nkk[k][l] has
382: (4)                    not reached its target yet i.e. (for given k,l): n_edges_add < nkk[k][l].
383: (4)                    It then adds edge (v,w) and always increases the number of edges in graph
G
384: (4)                    by one.
385: (4)                    The intelligence of the algorithm lies in the fact that  it is always
386: (4)                    possible to add an edge between disconnected nodes v and w, for which
387: (4)                    nkk[degree(v)][degree(w)] has not reached its target, even if one or both
388: (4)                    nodes do not have free stubs. If either node v or w does not have a free
389: (4)                    stub, we perform a "neighbor switch", an edge rewiring move that releases
a
390: (4)                    free stub while keeping nkk the same.
391: (4)                    The difference for the directed version lies in the fact that neighbor
392: (4)                    switches might not be able to rewire, but in these cases unsaturated nodes
393: (4)                    can be reassigned to use instead, see [1] for detailed description and
394: (4)                    proofs.
395: (4)                    The algorithm continues for E (number of edges in the graph) iterations of
396: (4)                    the "while loop", at which point all entries of the given nkk[k][l] have
397: (4)                    reached their target values and the construction is complete.

    The dimension *n* is the length of the list `dim` and the size in
    each dimension is the value of the corresponding list element.
    Parameters
    ----------
    dim : list or tuple of numbers or iterables of nodes
        'dim' is a tuple or list with, for each dimension, either a number
        that is the size of that dimension or an iterable of nodes for
        that dimension. The dimension of the grid_graph is the length
        of `dim`.
    periodic : bool or iterable
        If `periodic` is True, all dimensions are periodic. If False all
        dimensions are not periodic. If `periodic` is iterable, it should
        yield `dim` bool values each of which indicates whether the
        corresponding axis is periodic.
    Returns
    -------
    NetworkX graph
        The (possibly periodic) grid graph of the specified dimensions.
    Examples
    --------
    To produce a 2 by 3 by 4 grid graph, a graph on 24 nodes:
    >>> from networkx import grid_graph
    >>> G = grid_graph(dim=(2, 3, 4))
    >>> len(G)
    24
    >>> G = grid_graph(dim=(range(7, 9), range(3, 6)))

137: (4)                m, n, periodic=False, with_positions=True, create_using=None
138: (0)            ):
139: (4)                r"""Returns the $m$ by $n$ triangular lattice graph.
140: (4)                The `triangular lattice graph`_ is a two-dimensional `grid graph`_ in
141: (4)                which each square unit has a diagonal edge (each grid unit has a chord).
142: (4)                The returned graph has $m$ rows and $n$ columns of triangles. Rows and
143: (4)                columns include both triangles pointing up and down. Rows form a strip
144: (4)                of constant height. Columns form a series of diamond shapes, staggered
145: (4)                with the columns on either side. Another way to state the size is that
146: (4)                the nodes form a grid of `m+1` rows and `(n + 1) // 2` columns.
147: (4)                The odd row nodes are shifted horizontally relative to the even rows.
148: (4)                Directed graph types have edges pointed up or right.
149: (4)                Positions of nodes are computed by default or `with_positions is True`.
150: (4)                The position of each node (embedded in a euclidean plane) is stored in
151: (4)                the graph using equilateral triangles with sidelength 1.
152: (4)                The height between rows of nodes is thus $\sqrt(3)/2$.
153: (4)                Nodes lie in the first quadrant with the node $(0, 0)$ at the origin.
154: (4)                .. _triangular lattice graph:
http://mathworld.wolfram.com/TriangularGrid.html
155: (4)                .. _grid graph: http://www-cs-students.stanford.edu/~amitp/game-

220: (4)                The *hexagonal lattice graph* is a graph whose nodes and edges are
221: (4)                the `hexagonal tiling`_ of the plane.
222: (4)                The returned graph will have `m` rows and `n` columns of hexagons.
223: (4)                `Odd numbered columns`_ are shifted up relative to even numbered columns.
224: (4)                Positions of nodes are computed by default or `with_positions is True`.
225: (4)                Node positions creating the standard embedding in the plane
226: (4)                with sidelength 1 and are stored in the node attribute 'pos'.
227: (4)                `pos = nx.get_node_attributes(G, 'pos')` creates a dict ready for drawing.
228: (4)                .. _hexagonal tiling: https://en.wikipedia.org/wiki/Hexagonal_tiling
229: (4)                .. _Odd numbered columns: http://www-cs-students.stanford.edu/~amitp/game-
programming/grids/
```

```
    Parameters
    ----------
    m : int
        The number of rows of hexagons in the lattice.
    n : int
        The number of columns of hexagons in the lattice.
    periodic : bool
        Whether to make a periodic grid by joining the boundary vertices.
        For this to work `n` must be even and both `n > 1` and `m > 1`.
        The periodic connections create another row and column of hexagons
        so these graphs have fewer nodes as boundary nodes are identified.
    with_positions : bool (default: True)
        Store the coordinates of each node in the graph node attribute 'pos'.
        The coordinates provide a lattice with vertical columns of hexagons
        offset to interleave and cover the plane.
        Periodic positions shift the nodes vertically in a nonlinear way so
        the edges don't overlap so much.
    create_using : NetworkX graph constructor, optional (default=nx.Graph)
        Graph type to create. If graph instance, then cleared before populated.

        If graph is directed, edges will point up or right.
    Returns
    -------
    NetworkX graph
        The *m* by *n* hexagonal lattice graph.

(0)  from networkx.utils import arbitrary_element
(0)  from networkx.utils.decorators import not_implemented_for
(0)  __all__ = ["line_graph", "inverse_line_graph"]
(0)  @nx._dispatchable(returns_graph=True)
(0)  def line_graph(G, create_using=None):
(4)      r"""Returns the line graph of the graph or digraph `G`.
(4)      The line graph of a graph `G` has a node for each edge in `G` and an
(4)      edge joining those nodes if the two edges in `G` share a common node. For
(4)      directed graphs, nodes are adjacent exactly when the edges they represent
(4)      form a directed path of length two.
(4)      The nodes of the line graph are 2-tuples of nodes in the original graph (or
(4)      3-tuples for multigraphs, with the key of the edge as the third element).
(4)      For information about self-loops and more discussion, see the **Notes**
(4)      section below.
(4)      Parameters
(4)      ----------
(4)      G : graph
(8)          A NetworkX Graph, DiGraph, MultiGraph, or MultiDigraph.
(4)      create_using : NetworkX graph constructor, optional (default=nx.Graph)
(7)         Graph type to create. If graph instance, then cleared before populated.
(4)      Returns
(4)      -------
(4)      L : graph
(8)          The line graph of G.
(4)      Examples
(4)      --------
(4)      >>> G = nx.star_graph(3)
(4)      >>> L = nx.line_graph(G)
(4)      >>> print(sorted(map(sorted, L.edges())))  # makes a 3-clique, K3
(4)      [[(0, 1), (0, 2)], [(0, 1), (0, 3)], [(0, 2), (0, 3)]]
(4)      Edge attributes from `G` are not copied over as node attributes in `L`, but
(4)      attributes can be copied manually:
(4)      >>> G = nx.path_graph(4)
(4)      >>> G.add_edges_from((u, v, {"tot": u + v}) for u, v in G.edges)
(4)      >>> G.edges(data=True)
(4)      EdgeDataView([(0, 1, {'tot': 1}), (1, 2, {'tot': 3}), (2, 3, {'tot': 5})])
(4)      >>> H = nx.line_graph(G)
(4)      >>> H.add_nodes_from((node, G.edges[node]) for node in H)
(4)      >>> H.nodes(data=True)
(4)      NodeDataView({(0, 1): {'tot': 1}, (2, 3): {'tot': 5}, (1, 2): {'tot': 3}})
(4)      Notes
(4)      -----
(4)      Graph, node, and edge data are not propagated to the new graph. For
(4)      undirected graphs, the nodes in G must be sortable, otherwise the
(4)      constructed line graph may not be correct.
(4)      *Self-loops in undirected graphs*
(4)      For an undirected graph `G` without multiple edges, each edge can be
(4)      written as a set `\{u, v\}`.  Its line graph `L` has the edges of `G` as
(4)      its nodes. If `x` and `y` are two nodes in `L`, then `\{x, y\}` is an edge
(4)      in `L` if and only if the intersection of `x` and `y` is nonempty. Thus,
(4)      the set of all edges is determined by the set of all pairwise intersections
(4)      of edges in `G`.
(4)      Trivially, every edge in G would have a nonzero intersection with itself,
(4)      and so every node in `L` should have a self-loop. This is not so
(4)      interesting, and the original context of line graphs was with simple
(4)      graphs, which had no self-loops or multiple edges. The line graph was also
(4)      meant to be a simple graph and thus, self-loops in `L` are not part of the
(4)      standard definition of a line graph. In a pairwise intersection matrix,
(4)      this is analogous to excluding the diagonal entries from the line graph
(4)      definition.
(4)      Self-loops and multiple edges in `G` add nodes to `L` in a natural way,
```

```
and
67: (4)                 do not require any fundamental changes to the definition. It might be
68: (4)                 argued that the self-loops we excluded before should now be included.
69: (4)                 However, the self-loops are still "trivial" in some sense and thus, are
70: (4)                 usually excluded.
71: (4)                 *Self-loops in directed graphs*
72: (4)                 For a directed graph `G` without multiple edges, each edge can be written
73: (4)                 as a tuple `(u, v)`. Its line graph `L` has the edges of `G` as its
74: (4)                 nodes. If `x` and `y` are two nodes in `L`, then `(x, y)` is an edge in
`L`
75: (4)                 if and only if the tail of `x` matches the head of `y`, for example, if `x
76: (4)                 = (a, b)` and `y = (b, c)` for some vertices `a`, `b`, and `c` in `G`.
77: (4)                 Due to the directed nature of the edges, it is no longer the case that
78: (4)                 every edge in `G` should have a self-loop in `L`. Now, the only time
79: (4)                 self-loops arise is if a node in `G` itself has a self-loop.  So such
80: (4)                 self-loops are no longer "trivial" but instead, represent essential
81: (4)                 features of the topology of `G`. For this reason, the historical
82: (4)                 development of line digraphs is such that self-loops are included. When
the
83: (4)                 graph `G` has multiple edges, once again only superficial changes are
84: (4)                 required to the definition.

def mycielskian(G, iterations=1):
    r"""Returns the Mycielskian of a simple, undirected graph G
    The Mycielskian of graph preserves a graph's triangle free
    property while increasing the chromatic number by 1.
    The Mycielski Operation on a graph, :math:`G=(V, E)`, constructs a new
    graph with :math:`2|V| + 1` nodes and :math:`3|E| + |V|` edges.
    The construction is as follows:
    Let :math:`V = {0, ..., n-1}`. Construct another vertex set
    :math:`U = {n, ..., 2n}` and a vertex, `w`.
    Construct a new graph, `M`, with vertices :math:`U \bigcup V \bigcup w`.
    For edges, :math:`(u, v) \in E` add edges :math:`(u, v), (u, v + n)`, and
    :math:`(u + n, v)` to M. Finally, for all vertices :math:`u \in U`, add
    edge :math:`(u, w)` to M.
    The Mycielski Operation can be done multiple times by repeating the above
    process iteratively.
    More information can be found at https://en.wikipedia.org/wiki/Mycielskian
    Parameters
    ----------
    G : graph
        A simple, undirected NetworkX graph
    iterations : int
        The number of iterations of the Mycielski operation to
        perform on G. Defaults to 1. Must be a non-negative integer.
    Returns
    -------
    M : graph
        The Mycielskian of G after the specified number of iterations.
    Notes
    -----
    Graph, node, and edge data are not necessarily propagated to the new graph.
    """

(4)                 """Returns a connected Watts–Strogatz small-world graph.
```

```
    Attempts to generate a connected graph by repeated generation of
    Watts–Strogatz small-world graphs.  An exception is raised if the maximum
    number of tries is exceeded.
    Parameters
    ----------
    n : int
        The number of nodes
    k : int
        Each node is joined with its `k` nearest neighbors in a ring
        topology.
    p : float
        The probability of rewiring each edge
    tries : int
        Number of attempts to generate a connected graph.
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
    Notes
    -----
    First create a ring over $n$ nodes [1]_.  Then each node in the ring is joined
    to its $k$ nearest neighbors (or $k - 1$ neighbors if $k$ is odd).
    Then shortcuts are created by replacing some edges as follows: for each
    edge $(u, v)$ in the underlying "$n$-ring with $k$ nearest neighbors"
    with probability $p$ replace it with a new edge $(u, w)$ with uniformly
    random choice of existing node $w$.
    The entire process is repeated until a connected graph results.

    r"""Returns a random $d$-regular graph on $n$ nodes.
    A regular graph is a graph where each node has the same number of neighbors.
    The resulting graph has no self-loops or parallel edges.
    Parameters
    ----------
    d : int
      The degree of each node.
    n : integer
      The number of nodes. The value of $n \times d$ must be even.
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
    Notes
    -----
    The nodes are numbered from $0$ to $n - 1$.
    Kim and Vu's paper [2]_ shows that this algorithm samples in an
    asymptotically uniform way from the space of random graphs when
    $d = O(n^{1 / 3 - \epsilon})$.
    Raises
    ------
    NetworkXError
        If $n \times d$ is odd or $d$ is greater than or equal to $n$.

(4)             """Returns an extended Barabási–Albert model graph.
(4)             An extended Barabási–Albert model graph is a random graph constructed
(4)             using preferential attachment. The extended model allows new edges,
(4)             rewired edges or new nodes. Based on the probabilities $p$ and $q$
(4)             with $p + q < 1$, the growing behavior of the graph is determined as:
(4)             1) With $p$ probability, $m$ new edges are added to the graph,
(4)             starting from randomly chosen existing nodes and attached preferentially
at the other end.
(4)             2) With $q$ probability, $m$ existing edges are rewired
(4)             by randomly choosing an edge and rewiring one end to a preferentially
chosen node.
(4)             3) With $(1 - p - q)$ probability, $m$ new nodes are added to the graph
(4)             with edges attached preferentially.
(4)             When $p = q = 0$, the model behaves just like the Barabási–Alber model.
(4)             Parameters
(4)             ----------
(4)             n : int
(8)                 Number of nodes
(4)             m : int
(8)                 Number of edges with which a new node attaches to existing nodes
(4)             p : float
(8)                 Probability value for adding an edge between existing nodes. p + q < 1
(4)             q : float
(8)                 Probability value of rewiring of existing edges. p + q < 1
(4)             seed : integer, random_state, or None (default)
(8)                 Indicator of random number generation state.
(8)                 See :ref:`Randomness<randomness>`.
(4)             Returns
(4)             -------
(4)             G : Graph
(4)             Raises
(4)             ------
(4)             NetworkXError
(8)                 If `m` does not satisfy ``1 <= m < n`` or ``1 >= p + q``

743: (8)                    Indicator of random number generation state.
744: (8)                    See :ref:`Randomness<randomness>`.
745: (4)                Notes
746: (4)                -----
747: (4)                The average clustering has a hard time getting above a certain
748: (4)                cutoff that depends on `m`.  This cutoff is often quite low.  The
749: (4)                transitivity (fraction of triangles to possible triangles) seems to
750: (4)                decrease with network size.
751: (4)                It is essentially the Barabási–Albert (BA) growth model with an
752: (4)                extra step that each random edge is followed by a chance of
753: (4)                making an edge to one of its neighbors too (and thus a triangle).
754: (4)                This algorithm improves on BA in the sense that it enables a
```

```
    higher average clustering to be attained if desired.
    It seems possible to have a disconnected graph with this algorithm
    since the initial `m` nodes may not be all linked to a new node
    on the first iteration like the BA model.
    Raises
    ------
    NetworkXError
        If `m` does not satisfy ``1 <= m <= n`` or `p` does not
        satisfy ``0 <= p <= 1``.

29: (4)                  Returns
30: (4)                  -------
31: (4)                  G : MultiGraph
32: (8)                      A graph with the specified degree sequence. Nodes are labeled
33: (8)                      starting at 0 with an index corresponding to the position in
34: (8)                      deg_sequence.
35: (4)                  Raises
36: (4)                  ------
37: (4)                  NetworkXError
38: (8)                      If the independent edge degree sequence sum is not even
39: (8)                      or the triangle degree sequence sum is not divisible by 3.
40: (4)                  Notes
41: (4)                  -----
42: (4)                  As described by Miller [1]_ (see also Newman [2]_ for an equivalent
43: (4)                  description).
44: (4)                  A non-graphical degree sequence (not realizable by some simple
45: (4)                  graph) is allowed since this function returns graphs with self
46: (4)                  loops and parallel edges.  An exception is raised if the
47: (4)                  independent degree sequence does not have an even sum or the
48: (4)                  triangle degree sequence sum is not divisible by 3.
49: (4)                  This configuration model-like construction process can lead to
50: (4)                  duplicate edges and loops.  You can remove the self-loops and
51: (4)                  parallel edges (see below) which will likely result in a graph
52: (4)                  that doesn't have the exact degree sequence specified.  This
53: (4)                  "finite-size effect" decreases as the size of the graph increases.

(4)             Returns the Platonic Octahedral graph.
(4)             The octahedral graph is the 6-node 12-edge Platonic graph having the
(4)             connectivity of the octahedron [1]_. If 6 couples go to a party,
(4)             and each person shakes hands with every person except his or her partner,
(4)             then this graph describes the set of handshakes that take place;
(4)             for this reason it is also called the cocktail party graph [2]_.
(4)             Parameters
(4)             ----------
(4)             create_using : NetworkX graph constructor, optional (default=nx.Graph)
(7)                Graph type to create. If graph instance, then cleared before populated.
(4)             Returns
(4)             -------

13: (4)                 """Returns Zachary's Karate Club graph.
```

```
    Each node in the returned graph has a node attribute 'club' that
    indicates the name of the club to which the member represented by that
node
    belongs, either 'Mr. Hi' or 'Officer'. Each edge has a weight based on the
    number of contexts in which that edge's incident node members interacted.
    Examples
    --------
    To get the name of the club to which a node belongs::
        >>> G = nx.karate_club_graph()
        >>> G.nodes[5]["club"]
        'Mr. Hi'
        >>> G.nodes[9]["club"]
        'Officer'

29: (4)                 H : Graph
30: (8)                     A graph with a similar eigenvector structure of the input one.
31: (4)                 Raises
32: (4)                 ------
33: (4)                 NetworkXError
34: (8)                     If transformation has a value different from 'identity' or
'modularity'
35: (4)                 Notes
36: (4)                 -----
37: (4)                 Spectral Graph Forge (SGF) generates a random simple graph resembling the
38: (4)                 global properties of the given one.
39: (4)                 It leverages the low-rank approximation of the associated adjacency matrix
```

```
40: (4)                 driven by the *alpha* precision parameter.
41: (4)                 SGF preserves the number of nodes of the input graph and their ordering.
42: (4)                 This way, nodes of output graphs resemble the properties of the input one
43: (4)                 and attributes can be directly mapped.
44: (4)                 It considers the graph adjacency matrices which can optionally be
45: (4)                 transformed to other symmetric real matrices (currently transformation
46: (4)                 options include *identity* and *modularity*).
47: (4)                 The *modularity* transformation, in the sense of Newman's modularity
matrix
48: (4)                 allows the focusing on community structure related properties of the
graph.
49: (4)                 SGF applies a low-rank approximation whose fixed rank is computed from the
50: (4)                 ratio *alpha* of the input graph adjacency matrix dimension.
51: (4)                 This step performs a filtering on the input eigenvectors similar to the
low
52: (4)                 pass filtering common in telecommunications.
53: (4)                 The filtered values (after truncation) are used as input to a Bernoulli
54: (4)                 sampling for constructing a random adjacency matrix.

File 452 - sudoku.py:

```
"""Generator for Sudoku graphs
This module gives a generator for n-Sudoku graphs. It can be used to develop
algorithms for solving or generating Sudoku puzzles.
A completed Sudoku grid is a 9x9 array of integers between 1 and 9, with no
number appearing twice in the same row, column, or 3x3 box.
+---------+---------+---------+
| | 8 6 4 | | 3 7 1 | | 2 5 9 |
| | 3 2 5 | | 8 4 9 | | 7 6 1 |
| | 9 7 1 | | 2 6 5 | | 8 4 3 |
+---------+---------+---------+
| | 4 3 6 | | 1 9 2 | | 5 8 7 |
| | 1 9 8 | | 6 5 7 | | 4 3 2 |
| | 2 5 7 | | 4 8 3 | | 9 1 6 |
+---------+---------+---------+
| | 6 8 9 | | 7 3 4 | | 1 2 5 |
| | 7 1 3 | | 5 2 8 | | 6 9 4 |
| | 5 4 2 | | 9 1 6 | | 3 7 8 |
+---------+---------+---------+
The Sudoku graph is an undirected graph with 81 vertices, corresponding to
the cells of a Sudoku grid. It is a regular graph of degree 20. Two distinct
vertices are adjacent if and only if the corresponding cells belong to the
same row, column, or box. A completed Sudoku grid corresponds to a vertex
coloring of the Sudoku graph with nine colors.
More generally, the n-Sudoku graph is a graph with n^4 vertices, corresponding
to the cells of an n^2 by n^2 grid. Two distinct vertices are adjacent if and
only if they belong to the same row, column, or n by n box.

9: (4)                  """
10: (4)                 Return a Visibility Graph of an input Time Series.
11: (4)                 A visibility graph converts a time series into a graph. The constructed
graph
12: (4)                 uses integer nodes to indicate which event in the series the node
represents.
13: (4)                 Edges are formed as follows: consider a bar plot of the series and view
that
14: (4)                 as a side view of a landscape with a node at the top of each bar. An edge
15: (4)                 means that the nodes can be connected by a straight "line-of-sight"
without
16: (4)                 being obscured by any bars between the nodes.
17: (4)                 The resulting graph inherits several properties of the series in its
structure.
18: (4)                 Thereby, periodic series convert into regular graphs, random series
convert
19: (4)                 into random graphs, and fractal series convert into scale-free networks
[1]_.

File 454 - trees.py:

1: (0)              """Functions for generating trees.
2: (0)              The functions sampling trees at random in this module come
3: (0)              in two variants: labeled and unlabeled. The labeled variants
4: (0)              sample from every possible tree with the given number of nodes
5: (0)              uniformly at random. The unlabeled variants sample from every
6: (0)              possible *isomorphism class* of trees with the given number
7: (0)              of nodes uniformly at random.
8: (0)              To understand the difference, consider the following example.
9: (0)              There are two isomorphism classes of trees with four nodes.
10: (0)             One is that of the path graph, the other is that of the
11: (0)             star graph. The unlabeled variant will return a line graph or
12: (0)             a star graph with probability 1/2.
13: (0)             The labeled variant will return the line graph
14: (0)             with probability 3/4 and the star graph with probability 1/4,
15: (0)             because there are more labeled variants of the line graph
16: (0)             than of the star graph. More precisely, the line graph has
17: (0)             an automorphism group of order 2, whereas the star graph has
18: (0)             an automorphism group of order 6, so the line graph has three
19: (0)             times as many labeled variants as the star graph, and thus
20: (0)             three more chances to be drawn.
21: (0)             Additionally, some functions in this module can sample rooted
22: (0)             trees and forests uniformly at random. A rooted tree is a tree
23: (0)             with a designated root node. A rooted forest is a disjoint union
24: (0)             of rooted trees.
25: (0)             """

41: (0)             ]
42: (0)             @nx._dispatchable(graphs=None, returns_graph=True)
43: (0)             def prefix_tree(paths):
44: (4)                 """Creates a directed prefix tree from a list of paths.
45: (4)                 Usually the paths are described as strings or lists of integers.
46: (4)                 A "prefix tree" represents the prefix structure of the strings.
47: (4)                 Each node represents a prefix of some string. The root represents
48: (4)                 the empty prefix with children for the single letter prefixes which
49: (4)                 in turn have children for each double letter prefix starting with
50: (4)                 the single letter corresponding to the parent node, and so on.
51: (4)                 More generally the prefixes do not need to be strings. A prefix refers
52: (4)                 to the start of a sequence. The root has children for each one element
53: (4)                 prefix and they have children for each two element prefix that starts
54: (4)                 with the one element sequence of the parent, and so on.
```

```
    Note that this implementation uses integer nodes with an attribute.
    Each node has an attribute "source" whose value is the original element
    of the path to which this node corresponds. For example, suppose `paths`
    consists of one path: "can". Then the nodes `[1, 2, 3]` which represent
    this path have "source" values "c", "a" and "n".
    All the descendants of a node have a common prefix in the sequence/path
    associated with that node. From the returned tree, the prefix for each
    node can be constructed by traversing the tree up to the root and
    accumulating the "source" values along the way.
    The root node is always `0` and has "source" attribute `None`.
    The root is the only node with in-degree zero.
    The nil node is always `-1` and has "source" attribute `"NIL"`.
    The nil node is the only node with out-degree zero.
    Parameters
    ----------
    paths: iterable of paths
        An iterable of paths which are themselves sequences.
        Matching prefixes among these sequences are identified with
        nodes of the prefix tree. One leaf of the tree is associated
        with each path. (Identical paths are associated with the same
        leaf of the tree.)
    Returns
    -------
    tree: DiGraph
        A directed graph representing an arborescence consisting of the
        prefix tree generated by `paths`. Nodes are directed "downward",
        from parent to child. A special "synthetic" root node is added
        to be the parent of the first node in each path. A special
        "synthetic" leaf node, the "nil" node `-1`, is added to be the child
        of all nodes representing the last element in a path. (The
        addition of this nil node technically makes this not an
        arborescence but a directed acyclic graph; removing the nil node
        makes it an arborescence.)
    Notes
    -----
    The prefix tree is also known as a *trie*.
    Examples
    --------
    Create a prefix tree from a list of strings with common prefixes::
        >>> paths = ["ab", "abs", "ad"]
        >>> T = nx.prefix_tree(paths)
        >>> list(T.edges)
        [(0, 1), (1, 2), (1, 4), (2, -1), (2, 3), (3, -1), (4, -1)]
    The leaf nodes can be obtained as predecessors of the nil node::
        >>> root, NIL = 0, -1
        >>> list(T.predecessors(NIL))
        [2, 3, 4]
    To recover the original paths that generated the prefix tree,
    traverse up the tree from the node `-1` to the node `0`::
        >>> recovered = []
        >>> for v in T.predecessors(NIL):
        ...     prefix = ""
        ...     while v != root:
        ...         prefix = str(T.nodes[v]["source"]) + prefix
        ...         v = next(T.predecessors(v))  # only one predecessor
        ...     recovered.append(prefix)
        >>> sorted(recovered)
        ['ab', 'abs', 'ad']
    """
    def get_children(parent, paths):
        children = defaultdict(list)
        for path in paths:
            if not path:
                tree.add_edge(parent, NIL)
                continue
            child, *rest = path
            children[child].append(rest)
        return children
    tree = nx.DiGraph()
```

```
(4)                 root = 0
(4)                 tree.add_node(root, source=None)
(4)                 NIL = -1
(4)                 tree.add_node(NIL, source="NIL")
(4)                 children = get_children(root, paths)

(0)             @nx._dispatchable(graphs=None, returns_graph=True)
(0)             def prefix_tree_recursive(paths):
(4)                 """Recursively creates a directed prefix tree from a list of paths.
(4)                 The original recursive version of prefix_tree for comparison. It is
(4)                 the same algorithm but the recursion is unrolled onto a stack.
(4)                 Usually the paths are described as strings or lists of integers.
(4)                 A "prefix tree" represents the prefix structure of the strings.
(4)                 Each node represents a prefix of some string. The root represents
(4)                 the empty prefix with children for the single letter prefixes which
(4)                 in turn have children for each double letter prefix starting with
(4)                 the single letter corresponding to the parent node, and so on.
(4)                 More generally the prefixes do not need to be strings. A prefix refers
(4)                 to the start of a sequence. The root has children for each one element
(4)                 prefix and they have children for each two element prefix that starts
(4)                 with the one element sequence of the parent, and so on.
(4)                 Note that this implementation uses integer nodes with an attribute.
(4)                 Each node has an attribute "source" whose value is the original element
(4)                 of the path to which this node corresponds. For example, suppose `paths`
(4)                 consists of one path: "can". Then the nodes `[1, 2, 3]` which represent
(4)                 this path have "source" values "c", "a" and "n".
(4)                 All the descendants of a node have a common prefix in the sequence/path
(4)                 associated with that node. From the returned tree, ehe prefix for each
(4)                 node can be constructed by traversing the tree up to the root and
(4)                 accumulating the "source" values along the way.
(4)                 The root node is always `0` and has "source" attribute `None`.
(4)                 The root is the only node with in-degree zero.
(4)                 The nil node is always `-1` and has "source" attribute `"NIL"`.
(4)                 The nil node is the only node with out-degree zero.
(4)                 Parameters
(4)                 ----------
(4)                 paths: iterable of paths
(8)                     An iterable of paths which are themselves sequences.
(8)                     Matching prefixes among these sequences are identified with
(8)                     nodes of the prefix tree. One leaf of the tree is associated
(8)                     with each path. (Identical paths are associated with the same
(8)                     leaf of the tree.)
(4)                 Returns
(4)                 -------
(4)                 tree: DiGraph
(8)                     A directed graph representing an arborescence consisting of the
(8)                     prefix tree generated by `paths`. Nodes are directed "downward",
(8)                     from parent to child. A special "synthetic" root node is added
(8)                     to be the parent of the first node in each path. A special
(8)                     "synthetic" leaf node, the "nil" node `-1`, is added to be the child
(8)                     of all nodes representing the last element in a path. (The
(8)                     addition of this nil node technically makes this not an
(8)                     arborescence but a directed acyclic graph; removing the nil node
(8)                     makes it an arborescence.)
(4)                 Notes
(4)                 -----
```

```
    The prefix tree is also known as a *trie*.
    Examples
    --------
    Create a prefix tree from a list of strings with common prefixes::
        >>> paths = ["ab", "abs", "ad"]
        >>> T = nx.prefix_tree(paths)
        >>> list(T.edges)
        [(0, 1), (1, 2), (1, 4), (2, -1), (2, 3), (3, -1), (4, -1)]
    The leaf nodes can be obtained as predecessors of the nil node.
        >>> root, NIL = 0, -1
        >>> list(T.predecessors(NIL))
        [2, 3, 4]
    To recover the original paths that generated the prefix tree,
    traverse up the tree from the node `-1` to the node `0`::
        >>> recovered = []
        >>> for v in T.predecessors(NIL):
        ...     prefix = ""
        ...     while v != root:
        ...         prefix = str(T.nodes[v]["source"]) + prefix
        ...         v = next(T.predecessors(v))  # only one predecessor
        ...     recovered.append(prefix)
        >>> sorted(recovered)
        ['ab', 'abs', 'ad']
    """
    def _helper(paths, root, tree):
        """Recursively create a trie from the given list of paths.
        `paths` is a list of paths, each of which is itself a list of
        nodes, relative to the given `root` (but not including it). This
        list of paths will be interpreted as a tree-like structure, in
        which two paths that share a prefix represent two branches of
        the tree with the same initial segment.
        `root` is the parent of the node at index 0 in each path.
        `tree` is the "accumulator", the :class:`networkx.DiGraph`
        representing the branching to which the new nodes and edges will
        be added.
        """
        children = defaultdict(list)
        for path in paths:
            if not path:
                tree.add_edge(root, NIL)
                continue
            child, *rest = path
            children[child].append(rest)
        for child, remaining_paths in children.items():
            new_name = len(tree) - 1
            tree.add_node(new_name, source=child)
            tree.add_edge(root, new_name)
            _helper(remaining_paths, new_name, tree)
    tree = nx.DiGraph()
    root = 0
    tree.add_node(root, source=None)
    NIL = -1
    tree.add_node(NIL, source="NIL")
    _helper(paths, root, tree)
    return tree
@py_random_state(1)
@nx._dispatchable(graphs=None, returns_graph=True)
def random_tree(n, seed=None, create_using=None):
    """Returns a uniformly random tree on `n` nodes.
    .. deprecated:: 3.2
       ``random_tree`` is deprecated and will be removed in NX v3.4
       Use ``random_labeled_tree`` instead.
    Parameters
    ----------
    n : int
        A positive integer representing the number of nodes in the tree.
    seed : integer, random_state, or None (default)
        Indicator of random number generation state.
        See :ref:`Randomness<randomness>`.
```

```
    create_using : NetworkX graph constructor, optional (default=nx.Graph)
        Graph type to create. If graph instance, then cleared before
populated.

    Returns
    -------
    NetworkX graph
        A tree, given as an undirected graph, whose nodes are numbers in
        the set {0, …, *n* - 1}.
    Raises
    ------
    NetworkXPointlessConcept
        If `n` is zero (because the null graph is not a tree).
    Notes
    -----
    The current implementation of this function generates a uniformly
    random Prüfer sequence then converts that to a tree via the
    :func:`~networkx.from_prufer_sequence` function. Since there is a
    bijection between Prüfer sequences of length *n* - 2 and trees on
    *n* nodes, the tree is chosen uniformly at random from the set of
    all trees on *n* nodes.
    Examples
    --------
    >>> tree = nx.random_tree(n=10, seed=0)
    >>> nx.write_network_text(tree, sources=[0])

(4)             Returns
(4)             -------
(4)             :class:`networkx.Graph` or list of :class:`networkx.Graph`
(8)                 A single `networkx.Graph` (or a list thereof, if `number_of_trees`
(8)                 is specified) with nodes in the set {0, …, *n* - 1}.
(8)                 The "root" graph attribute identifies the root of the tree.
(4)             Notes
(4)             -----
(4)             The trees are generated using the "RANRUT" algorithm from [1]_.
(4)             The algorithm needs to compute some counting functions
(4)             that are relatively expensive: in case several trees are needed,
(4)             it is advisable to use the `number_of_trees` optional argument
(4)             to reuse the counting functions.
(4)             Raises
(4)             ------
(4)             NetworkXPointlessConcept
(8)                 If `n` is zero (because the null graph is not a tree).

35: (4)                 """Returns a function that returns a value from G[u][v].
36: (4)                 Suppose there exists an edge between u and v.  Then we return a function
37: (4)                 expecting u and v as arguments.  For Graph and DiGraph, G[u][v] is
38: (4)                 the edge attribute dictionary, and the function (essentially) returns
39: (4)                 G[u][v][edge_attr].  However, we also handle cases when `edge_attr` is
None
40: (4)                 and when it is a function itself. For MultiGraph and MultiDiGraph, G[u][v]
41: (4)                 is a dictionary of all edges between u and v.  In this case, the returned
```

```
    function sums the value of `edge_attr` for every edge between u and v.
    Parameters
    ----------
    G : graph
       A NetworkX graph
    edge_attr : {None, str, callable}
        Specification of how the value of the edge attribute should be obtained

        from the edge attribute dictionary, G[u][v].  For multigraphs, G[u][v]
        is a dictionary of all the edges between u and v.  This allows for
        special treatment of multiedges.
    Returns
    -------
    value : function
        A function expecting two nodes as parameters. The nodes should
        represent the from- and to- node of an edge. The function will
        return a value from G[u][v] that depends on `edge_attr`.
    """

def attr_matrix(
    G,
    edge_attr=None,
    node_attr=None,
    normalized=False,
    rc_order=None,
    dtype=None,
    order=None,
):
    """Returns the attribute matrix using attributes from `G` as a numpy array.
    If only `G` is passed in, then the adjacency matrix is constructed.
    Let A be a discrete set of values for the node attribute `node_attr`. Then
    the elements of A represent the rows and columns of the constructed matrix.
    Now, iterate through every edge e=(u,v) in `G` and consider the value
    of the edge attribute `edge_attr`.  If ua and va are the values of the
    node attribute `node_attr` for u and v, respectively, then the value of
    the edge attribute is added to the matrix element at (ua, va).
    Parameters
    ----------
    G : graph
        The NetworkX graph used to construct the attribute matrix.
    edge_attr : str, optional
        Each element of the matrix represents a running total of the
```

```
    specified edge attribute for edges whose node attributes correspond
    to the rows/cols of the matrix. The attribute must be present for
    all edges in the graph. If no attribute is specified, then we
    just count the number of edges whose node attributes correspond
    to the matrix element.
node_attr : str, optional
    Each row and column in the matrix represents a particular value
    of the node attribute.  The attribute must be present for all nodes
    in the graph. Note, the values of this attribute should be reliably
    hashable. So, float values are not recommended. If no attribute is
    specified, then the rows and columns will be the nodes of the graph.
normalized : bool, optional
    If True, then each row is normalized by the summation of its values.
rc_order : list, optional
    A list of the node attribute values. This list specifies the ordering
    of rows and columns of the array. If no ordering is provided, then
    the ordering will be random (and also, a return value).
Other Parameters
----------------
dtype : NumPy data-type, optional
    A valid NumPy dtype used to initialize the array. Keep in mind certain
    dtypes can yield unexpected results if the array is to be normalized.
    The parameter is passed to numpy.zeros(). If unspecified, the NumPy
    default is used.
order : {'C', 'F'}, optional
    Whether to store multidimensional data in C- or Fortran-contiguous
    (row- or column-wise) order in memory. This parameter is passed to
    numpy.zeros(). If unspecified, the NumPy default is used.
Returns
-------
M : 2D NumPy ndarray
    The attribute matrix.
ordering : list
    If `rc_order` was specified, then only the attribute matrix is returned.

    However, if `rc_order` was None, then the ordering used to construct
    the matrix is returned as well.
Examples
--------
Construct an adjacency matrix:
>>> G = nx.Graph()
>>> G.add_edge(0, 1, thickness=1, weight=3)
>>> G.add_edge(0, 2, thickness=2)
>>> G.add_edge(1, 2, thickness=3)
>>> nx.attr_matrix(G, rc_order=[0, 1, 2])
array([[0., 1., 1.],
       [1., 0., 1.],
       [1., 1., 0.]])
Alternatively, we can obtain the matrix describing edge thickness.
>>> nx.attr_matrix(G, edge_attr="thickness", rc_order=[0, 1, 2])
array([[0., 1., 2.],
       [1., 0., 3.],
       [2., 3., 0.]])
We can also color the nodes and ask for the probability distribution over
all edges (u,v) describing:
    Pr(v has color Y | u has color X)
>>> G.nodes[0]["color"] = "red"
>>> G.nodes[1]["color"] = "red"
>>> G.nodes[2]["color"] = "blue"
>>> rc = ["red", "blue"]
>>> nx.attr_matrix(G, node_attr="color", normalized=True, rc_order=rc)
array([[0.33333333, 0.66666667],
       [1.        , 0.        ]])
For example, the above tells us that for all edges (u,v):
    Pr( v is red  | u is red)  = 1/3
    Pr( v is blue | u is red)  = 2/3
    Pr( v is red  | u is blue) = 1
    Pr( v is blue | u is blue) = 0
Finally, we can obtain the total weights listed by the node colors.
```

```
(4)                 >>> nx.attr_matrix(G, edge_attr="weight", node_attr="color", rc_order=rc)
(4)                 array([[3., 2.],
(11)                       [2., 0.]])
(4)                 Thus, the total weight over all edges (u,v) with u and v having colors:
(8)                     (red, red)   is 3   # the sole contribution is from edge (0,1)
(8)                     (red, blue)  is 2   # contributions from edges (0,2) and (1,2)
(8)                     (blue, red)  is 2   # same as (red, blue) since graph is undirected
(8)                     (blue, blue) is 0   # there are no edges with blue endpoints
(4)                 """

        The parameter is passed to numpy.zeros(). If unspecified, the NumPy
        default is used.
    Returns
    -------
    M : SciPy sparse array
        The attribute matrix.
    ordering : list
        If `rc_order` was specified, then only the matrix is returned.
        However, if `rc_order` was None, then the ordering used to construct
        the matrix is returned as well.
    Examples
    --------
    Construct an adjacency matrix:
    >>> G = nx.Graph()
    >>> G.add_edge(0, 1, thickness=1, weight=3)
    >>> G.add_edge(0, 2, thickness=2)
    >>> G.add_edge(1, 2, thickness=3)
    >>> M = nx.attr_sparse_matrix(G, rc_order=[0, 1, 2])
    >>> M.toarray()
    array([[0., 1., 1.],
           [1., 0., 1.],
           [1., 1., 0.]])
    Alternatively, we can obtain the matrix describing edge thickness.
    >>> M = nx.attr_sparse_matrix(G, edge_attr="thickness", rc_order=[0, 1, 2])
    >>> M.toarray()
    array([[0., 1., 2.],
           [1., 0., 3.],
           [2., 3., 0.]])
    We can also color the nodes and ask for the probability distribution over
    all edges (u,v) describing:
        Pr(v has color Y | u has color X)
    >>> G.nodes[0]["color"] = "red"
    >>> G.nodes[1]["color"] = "red"
    >>> G.nodes[2]["color"] = "blue"
    >>> rc = ["red", "blue"]
    >>> M = nx.attr_sparse_matrix(G, node_attr="color", normalized=True, rc_order=rc)
    >>> M.toarray()
    array([[0.33333333, 0.66666667],
           [1.        , 0.        ]])
    For example, the above tells us that for all edges (u,v):
        Pr( v is red  | u is red)  = 1/3
        Pr( v is blue | u is red)  = 2/3
        Pr( v is red  | u is blue) = 1
        Pr( v is blue | u is blue) = 0
    Finally, we can obtain the total weights listed by the node colors.
    >>> M = nx.attr_sparse_matrix(G, edge_attr="weight", node_attr="color", rc_order=rc)
    >>> M.toarray()
    array([[3., 2.],
           [2., 0.]])
    Thus, the total weight over all edges (u,v) with u and v having colors:

21: (4)                 A is the adjacency matrix and D is the diagonal matrix of node degrees.
22: (4)                 Parameters
23: (4)                 ----------
24: (4)                 G : graph
```

```
 25: (7)                    A NetworkX graph
 26: (4)                 nodelist : list, optional
 27: (7)                    The rows and columns are ordered according to the nodes in nodelist.
 28: (7)                    If nodelist is None, then the ordering is produced by G.nodes().
 29: (4)                 weight : string or None, optional (default='weight')
 30: (7)                    The edge data key used to compute each value in the matrix.
 31: (7)                    If None, then each edge has weight 1.
 32: (4)                 Returns
 33: (4)                 -------
 34: (4)                 L : SciPy sparse array
 35: (6)                   The Laplacian matrix of G.
 36: (4)                 Notes
 37: (4)                 -----
 38: (4)                 For MultiGraph, the edges weights are summed.
 39: (4)                 This returns an unnormalized matrix. For a normalized output,
 40: (4)                 use `normalized_laplacian_matrix`, `directed_laplacian_matrix`,
 41: (4)                 or `directed_combinatorial_laplacian_matrix`.
 42: (4)                 This calculation uses the out-degree of the graph `G`. To use the
 43: (4)                 in-degree for calculations instead, use `G.reverse(copy=False)` and
 44: (4)                 take the transpose.
 45: (4)                 See Also

File 503 - edgelist.py:

1: (0)              """
2: (0)              **********
3: (0)              Edge Lists
4: (0)              **********
5: (0)              Read and write NetworkX graphs as edge lists.
6: (0)              The multi-line adjacency list format is useful for graphs with nodes
7: (0)              that can be meaningfully represented as strings.  With the edgelist
8: (0)              format simple edge data can be stored but node or graph data is not.
9: (0)              There is no way of representing isolated nodes unless the node has a
10: (0)             self-loop edge.
11: (0)             Format
12: (0)             ------
13: (0)             You can read or write three formats of edge lists with these functions.
14: (0)             Node pairs with no data::
15: (1)              1 2
16: (0)             Python dictionary as data::
17: (1)              1 2 {'weight':7, 'color':'green'}
18: (0)             Arbitrary data::
19: (1)              1 2 7 green
20: (0)             """

33: (4)                 Parameters
```

```
    ----------
    G : NetworkX graph
    delimiter : string, optional
       Separator for node labels
    data : bool or list of keys
       If False generate no edge data.  If True use a dictionary
       representation of edge data.  If a list of keys use a list of data
       values corresponding to the keys.
    Returns
    -------
    lines : string
        Lines of data in adjlist format.
    Examples
    --------
    >>> G = nx.lollipop_graph(4, 3)
    >>> G[1][2]["weight"] = 3
    >>> G[3][4]["capacity"] = 12
    >>> for line in nx.generate_edgelist(G, data=False):

 110: (4)               "GEXF (Graph Exchange XML Format) is a language for describing
 111: (4)               complex networks structures, their associated data and dynamics" [1]_.
 112: (4)               Parameters
 113: (4)               ----------
 114: (4)               path : file or string
 115: (7)                  File or file name to read.
 116: (7)                  File names ending in .gz or .bz2 will be decompressed.
 117: (4)               node_type: Python type (default: None)
 118: (7)                  Convert node ids to this type if not None.
 119: (4)               relabel : bool (default: False)
 120: (7)                  If True relabel the nodes to use the GEXF node "label" attribute
 121: (7)                  instead of the node "id" attribute as the NetworkX node label.
 122: (4)               version : string (default: 1.2draft)
 123: (4)               Version of GEFX File Format (see http://gexf.net/schema.html)
 124: (7)                  Supported values: "1.1draft", "1.2draft"
 125: (4)               Returns
 126: (4)               -------
 127: (4)               graph: NetworkX graph
 128: (8)                   If no parallel edges are found a Graph or DiGraph is returned.
 129: (8)                   Otherwise a MultiGraph or MultiDiGraph is returned.
 130: (4)               Notes
 131: (4)               -----
 132: (4)               This implementation does not support mixed graphs (directed and undirected
 133: (4)               edges together).
 134: (4)               References

File 505 - gml.py:

```
1: (0)              """
2: (0)              Read graphs in GML format.
3: (0)              "GML, the Graph Modelling Language, is our proposal for a portable
4: (0)              file format for graphs. GML's key features are portability, simple
5: (0)              syntax, extensibility and flexibility. A GML file consists of a
6: (0)              hierarchical key-value lists. Graphs can be annotated with arbitrary
7: (0)              data structures. The idea for a common file format was born at the
```

```
 8: (0)              GD'95; this proposal is the outcome of many discussions. GML is the
 9: (0)              standard file format in the Graphlet graph editor system. It has been
 10: (0)             overtaken and adapted by several other systems for drawing graphs."
 11: (0)             GML files are stored using a 7-bit ASCII encoding with any extended
 12: (0)             ASCII characters (iso8859-1) appearing as HTML character entities.
 13: (0)             You will need to give some thought into how the exported data should
 14: (0)             interact with different languages and even different Python versions.
 15: (0)             Re-importing from gml is also a concern.
 16: (0)             Without specifying a `stringizer`/`destringizer`, the code is capable of
 17: (0)             writing `int`/`float`/`str`/`dict`/`list` data as required by the GML
 18: (0)             specification.  For writing other data types, and for reading data other
 19: (0)             than `str` you need to explicitly supply a `stringizer`/`destringizer`.
 20: (0)             For additional documentation on the GML file format, please see the
 21: (0)             `GML website <https://web.archive.org/web/20190207140002/http://www.fim.uni-
passau.de/index.php?id=17297&L=1>`_.
 22: (0)             Several example graphs in GML format may be found on Mark Newman's
 23: (0)             `Network data page <http://www-personal.umich.edu/~mejn/netdata/>`_.

(4)                 r"""Generate a single entry of the graph `G` in GML format.
(4)                 Parameters
(4)                 ----------
(4)                 G : NetworkX graph
(8)                     The graph to be converted to GML.
(4)                 stringizer : callable, optional
(8)                     A `stringizer` which converts non-int/non-float/non-dict values into
(8)                     strings. If it cannot convert a value into a string, it should raise a
(8)                     `ValueError` to indicate that. Default value: None.
(4)                 Returns
(4)                 -------
(4)                 lines: generator of strings
(8)                     Lines of GML data. Newlines are not appended.
(4)                 Raises
(4)                 ------
(4)                 NetworkXError
(8)                     If `stringizer` cannot convert a value into a string, or the value to
(8)                     convert is not a string while `stringizer` is None.
(4)                 See Also
(4)                 --------
(4)                 literal_stringizer
(4)                 Notes
(4)                 -----
(4)                 Graph attributes named 'directed', 'multigraph', 'node' or
(4)                 'edge', node attributes named 'id' or 'label', edge attributes
(4)                 named 'source' or 'target' (or 'key' if `G` is a multigraph)
(4)                 are ignored because these attribute names are used to encode the graph
(4)                 structure.
(4)                 GML files are stored using a 7-bit ASCII encoding with any extended
(4)                 ASCII characters (iso8859-1) appearing as HTML character entities.
(4)                 Without specifying a `stringizer`/`destringizer`, the code is capable of
(4)                 writing `int`/`float`/`str`/`dict`/`list` data as required by the GML
(4)                 specification.  For writing other data types, and for reading data other
(4)                 than `str` you need to explicitly supply a `stringizer`/`destringizer`.
(4)                 For additional documentation on the GML file format, please see the
(4)                 `GML url <https://web.archive.org/web/20190207140002/http://www.fim.uni-

699: (4)                Notes
700: (4)                -----
701: (4)                Graph attributes named 'directed', 'multigraph', 'node' or
702: (4)                'edge', node attributes named 'id' or 'label', edge attributes
703: (4)                named 'source' or 'target' (or 'key' if `G` is a multigraph)
704: (4)                are ignored because these attribute names are used to encode the graph
705: (4)                structure.
706: (4)                GML files are stored using a 7-bit ASCII encoding with any extended
707: (4)                ASCII characters (iso8859-1) appearing as HTML character entities.
708: (4)                Without specifying a `stringizer`/`destringizer`, the code is capable of
709: (4)                writing `int`/`float`/`str`/`dict`/`list` data as required by the GML
710: (4)                specification.  For writing other data types, and for reading data other
711: (4)                than `str` you need to explicitly supply a `stringizer`/`destringizer`.
712: (4)                Note that while we allow non-standard GML to be read from a file, we make
713: (4)                sure to write GML format. In particular, underscores are not allowed in
714: (4)                attribute names.
715: (4)                For additional documentation on the GML file format, please see the
716: (4)                `GML url <https://web.archive.org/web/20190207140002/http://www.fim.uni-
passau.de/index.php?id=17297&L=1>`_.
717: (4)                See the module docstring :mod:`networkx.readwrite.gml` for more details.
718: (4)                Examples
719: (4)                --------
720: (4)                >>> G = nx.path_graph(4)
721: (4)                >>> nx.write_gml(G, "test.gml")
722: (4)                Filenames ending in .gz or .bz2 will be compressed.
723: (4)                >>> nx.write_gml(G, "test.gml.gz")
724: (4)                """
725: (4)                for line in generate_gml(G, stringizer):
726: (8)                    path.write((line + "\n").encode("ascii"))

(7)                    given by ``G.nodes()`` is used.
(4)                 header: bool
(7)                    If True add '>>graph6<<' string to head of data
(4)                 Raises
(4)                 ------
(4)                 NetworkXNotImplemented
(8)                     If the graph is directed or is a multigraph.
(4)                 ValueError
(8)                     If the graph has at least ``2 ** 36`` nodes; the graph6 format
(8)                     is only defined for graphs of order less than ``2 ** 36``.
(4)                 Examples
(4)                 --------
(4)                 You can write a graph6 file by giving an open file-like object::
(8)                     >>> import tempfile
(8)                     >>> with tempfile.NamedTemporaryFile() as f:
(8)                     ...     nx.write_graph6(nx.path_graph(2), f)
(8)                     ...     _ = f.seek(0)
(8)                     ...     print(f.read())
(8)                     b'>>graph6<<A_\\n'
(4)                 See Also
(4)                 --------
(4)                 from_graph6_bytes, read_graph6
(4)                 Notes
(4)                 -----
(4)                 The function writes a newline character after writing the encoding
(4)                 of the graph.
(4)                 The format does not support edge or node labels, parallel edges or
(4)                 self loops.  If self loops are present they are silently ignored.

```
1: (0)              """
2: (0)              *******
3: (0)              GraphML
4: (0)              *******
5: (0)              Read and write graphs in GraphML format.
6: (0)              .. warning::
7: (4)                  This parser uses the standard xml library present in Python, which is
8: (4)                  insecure - see :external+python:mod:`xml` for additional information.
9: (4)                  Only parse GraphML files you trust.
10: (0)             This implementation does not support mixed graphs (directed and unidirected
11: (0)             edges together), hyperedges, nested graphs, or ports.
12: (0)             "GraphML is a comprehensive and easy-to-use file format for graphs. It
13: (0)             consists of a language core to describe the structural properties of a
14: (0)             graph and a flexible extension mechanism to add application-specific
15: (0)             data. Its main features include support of
16: (4)                 * directed, undirected, and mixed graphs,
17: (4)                 * hypergraphs,
18: (4)                 * hierarchical graphs,
19: (4)                 * graphical representations,
20: (4)                 * references to external data,
21: (4)                 * application-specific attribute data, and
22: (4)                 * light-weight parsers.
23: (0)             Unlike many other file formats for graphs, GraphML does not use a
24: (0)             custom syntax. Instead, it is based on XML and hence ideally suited as
25: (0)             a common denominator for all kinds of services generating, archiving,
26: (0)             or processing graphs."
27: (0)             http://graphml.graphdrawing.org/
28: (0)             Format
29: (0)             ------
30: (0)             GraphML is an XML format.  See
31: (0)             http://graphml.graphdrawing.org/specification.html for the specification and
32: (0)             http://graphml.graphdrawing.org/primer/graphml-primer.html
33: (0)             for examples.

----------------------------------------

File 510 - p2g.py:

1: (0)              """
2: (0)              This module provides the following: read and write of p2g format
3: (0)              used in metabolic pathway studies.
4: (0)              See
https://web.archive.org/web/20080626113807/http://www.cs.purdue.edu/homes/koyuturk/pathway/ for a
description.
5: (0)              The summary is included here:
6: (0)              A file that describes a uniquely labeled graph (with extension ".gr")
7: (0)              format looks like the following:
8: (0)              name
9: (0)              3 4
10: (0)             a
11: (0)             1 2
12: (0)             b
13: (0)             c
14: (0)             0 2
15: (0)             "name" is simply a description of what the graph corresponds to. The
16: (0)             second line displays the number of nodes and number of edges,
```

```
(0)             respectively. This sample graph contains three nodes labeled "a", "b",
(0)             and "c". The rest of the graph contains two lines for each node. The
(0)             first line for a node contains the node label. After the declaration
(0)             of the node label, the out-edges of that node in the graph are
(0)             provided. For instance, "a" is linked to nodes 1 and 2, which are
(0)             labeled "b" and "c", while the node labeled "b" has no outgoing
(0)             edges. Observe that node labeled "c" has an outgoing edge to
(0)             itself. Indeed, self-loops are allowed. Node index starts from 0.

(4)                 """Generate lines in the "network text" format
(4)                 This works via a depth-first traversal of the graph and writing a line for
(4)                 each unique node encountered. Non-tree edges are written to the right of
(4)                 each node, and connection to a non-tree edge is indicated with an
ellipsis.
(4)                 This representation works best when the input graph is a forest, but any
(4)                 graph can be represented.
(4)                 This notation is original to networkx, although it is simple enough that
it
(4)                 may be known in existing literature. See #5602 for details. The procedure
(4)                 is summarized as follows:
(4)                 1. Given a set of source nodes (which can be specified, or automatically
(4)                 discovered via finding the (strongly) connected components and choosing
one
(4)                 node with minimum degree from each), we traverse the graph in depth first
(4)                 order.
(4)                 2. Each reachable node will be printed exactly once on it's own line.
(4)                 3. Edges are indicated in one of four ways:
(8)                     a. a parent "L-style" connection on the upper left. This corresponds
to
(8)                     a traversal in the directed DFS tree.
```

```
            b. a backref "<-style" connection shown directly on the right. For
            directed graphs, these are drawn for any incoming edges to a node that
            is not a parent edge. For undirected graphs, these are drawn for only
            the non-parent edges that have already been represented (The edges that

            have not been represented will be handled in the recursive case).
            c. a child "L-style" connection on the lower right. Drawing of the
            children are handled recursively.
            d. if ``vertical_chains`` is true, and a parent node only has one child

            a "vertical-style" edge is drawn between them.
        4. The children of each node (wrt the directed DFS tree) are drawn
        underneath and to the right of it. In the case that a child node has already

        been drawn the connection is replaced with an ellipsis ("...") to indicate
        that there is one or more connections represented elsewhere.
        5. If a maximum depth is specified, an edge to nodes past this maximum
        depth will be represented by an ellipsis.
        6. If a a node has a truthy "collapse" value, then we do not traverse past
        that node.
        Parameters
        ----------
        graph : nx.DiGraph | nx.Graph
            Graph to represent
        with_labels : bool | str
            If True will use the "label" attribute of a node to display if it
            exists otherwise it will use the node value itself. If given as a
            string, then that attribute name will be used instead of "label".
            Defaults to True.
        sources : List
            Specifies which nodes to start traversal from. Note: nodes that are not

            reachable from one of these sources may not be shown. If unspecified,
            the minimal set of nodes needed to reach all others will be used.
        max_depth : int | None
            The maximum depth to traverse before stopping. Defaults to None.
        ascii_only : Boolean
            If True only ASCII characters are used to construct the visualization
        vertical_chains : Boolean
            If True, chains of nodes will be drawn vertically when possible.
        Yields
        ------
        str : a line of generated text
        Examples
        --------
        >>> graph = nx.path_graph(10)

339: (8)                    If True will use the "label" attribute of a node to display if it
340: (8)                    exists otherwise it will use the node value itself. If given as a
341: (8)                    string, then that attribute name will be used instead of "label".
342: (8)                    Defaults to True.
343: (4)                sources : List
344: (8)                    Specifies which nodes to start traversal from. Note: nodes that are
```

```
not
                    reachable from one of these sources may not be shown. If unspecified,
                    the minimal set of nodes needed to reach all others will be used.
                max_depth : int | None
                    The maximum depth to traverse before stopping. Defaults to None.
                ascii_only : Boolean
                    If True only ASCII characters are used to construct the visualization
                end : string
                    The line ending character
                vertical_chains : Boolean
                    If True, chains of nodes will be drawn vertically when possible.

    """Creates a nice utf8 representation of a forest
    This function has been superseded by
    :func:`nx.readwrite.text.generate_network_text`, which should be used
    instead.
    Parameters
    ----------
    graph : nx.DiGraph | nx.Graph
        Graph to represent (must be a tree, forest, or the empty graph)
    with_labels : bool
        If True will use the "label" attribute of a node to display if it
        exists otherwise it will use the node value itself. Defaults to True.
    sources : List
        Mainly relevant for undirected forests, specifies which nodes to list
        first. If unspecified the root nodes of each tree will be used for
        directed forests; for undirected forests this defaults to the nodes
        with the smallest degree.
    write : callable
        Function to use to write to, if None new lines are appended to
        a list and returned. If set to the `print` function, lines will
        be written to stdout as they are generated. If specified,
        this function will return None. Defaults to None.
    ascii_only : Boolean
        If True only ASCII characters are used to construct the visualization
    Returns
    -------
    str | None :
        utf8 representation of the tree / forest
    Examples
    --------
    >>> graph = nx.balanced_tree(r=2, h=3, create_using=nx.DiGraph)

53: (4)                 ------
54: (4)                 NetworkXError
55: (8)                     If the values of 'source', 'target' and 'key' are not unique.
56: (4)                 Examples
57: (4)                 --------
58: (4)                 >>> G = nx.Graph([("A", "B")])
59: (4)                 >>> data1 = nx.node_link_data(G)
```

```
60: (4)                 >>> data1
61: (4)                 {'directed': False, 'multigraph': False, 'graph': {}, 'nodes': [{'id':
'A'}, {'id': 'B'}], 'links': [{'source': 'A', 'target': 'B'}]}
62: (4)                 To serialize with JSON
63: (4)                 >>> import json
64: (4)                 >>> s1 = json.dumps(data1)
65: (4)                 >>> s1
66: (4)                 '{"directed": false, "multigraph": false, "graph": {}, "nodes": [{"id":
"A"}, {"id": "B"}], "links": [{"source": "A", "target": "B"}]}'
67: (4)                 A graph can also be serialized by passing `node_link_data` as an encoder
function. The two methods are equivalent.
68: (4)                 >>> s1 = json.dumps(G, default=nx.node_link_data)
69: (4)                 >>> s1
70: (4)                 '{"directed": false, "multigraph": false, "graph": {}, "nodes": [{"id":
"A"}, {"id": "B"}], "links": [{"source": "A", "target": "B"}]}'
71: (4)                 The attribute names for storing NetworkX-internal graph data can
72: (4)                 be specified as keyword options.
73: (4)                 >>> H = nx.gn_graph(2)
74: (4)                 >>> data2 = nx.node_link_data(H, link="edges", source="from", target="to")
75: (4)                 >>> data2
76: (4)                 {'directed': True, 'multigraph': False, 'graph': {}, 'nodes': [{'id': 0},
{'id': 1}], 'edges': [{'from': 1, 'to': 0}]}
77: (4)                 Notes
78: (4)                 -----
79: (4)                 Graph, node, and link attributes are stored in this format.  Note that
80: (4)                 attribute keys will be converted to strings in order to comply with JSON.
81: (4)                 Attribute 'key' is only used for multigraphs.
82: (4)                 To use `node_link_data` in conjunction with `node_link_graph`,
83: (4)                 the keyword names for the attributes must match.

```

```
(8)                     node-link formatted graph data
(4)                 directed : bool
(8)                     If True, and direction not specified in data, return a directed graph.
(4)                 multigraph : bool
(8)                     If True, and multigraph not specified in data, return a multigraph.
(4)                 source : string
(8)                     A string that provides the 'source' attribute name for storing
NetworkX-internal graph data.
(4)                 target : string
(8)                     A string that provides the 'target' attribute name for storing
NetworkX-internal graph data.
(4)                 name : string
(8)                     A string that provides the 'name' attribute name for storing NetworkX-
internal graph data.
(4)                 key : string
(8)                     A string that provides the 'key' attribute name for storing NetworkX-
internal graph data.
(4)                 link : string
(8)                     A string that provides the 'link' attribute name for storing NetworkX-
internal graph data.
(4)                 Returns
(4)                 -------
(4)                 G : NetworkX graph
(8)                     A NetworkX graph object
(4)                 Examples
(4)                 --------
(4)                 Create data in node-link format by converting a graph.
(4)                 >>> G = nx.Graph([("A", "B")])
(4)                 >>> data = nx.node_link_data(G)
(4)                 >>> data
(4)                 {'directed': False, 'multigraph': False, 'graph': {}, 'nodes': [{'id':
'A'}, {'id': 'B'}], 'links': [{'source': 'A', 'target': 'B'}]}
(4)                 Revert data in node-link format to a graph.
(4)                 >>> H = nx.node_link_graph(data)
(4)                 >>> print(H.edges)
(4)                 [('A', 'B')]
(4)                 To serialize and deserialize a graph with JSON,
(4)                 >>> import json
(4)                 >>> d = json.dumps(node_link_data(G))
(4)                 >>> H = node_link_graph(json.loads(d))
(4)                 >>> print(G.edges, H.edges)
(4)                 [('A', 'B')] [('A', 'B')]
(4)                 Notes
(4)                 -----
(4)                 Attribute 'key' is only used for multigraphs.
(4)                 To use `node_link_data` in conjunction with `node_link_graph`,
(4)                 the keyword names for the attributes must match.

```
----------------------------------------

File 547 - backends.py:

1: (0)              """
2: (0)              NetworkX utilizes a plugin-dispatch architecture, which means we can plug in
and
3: (0)              out of backends with minimal code changes. A valid NetworkX backend specifies
4: (0)              `entry points <https://packaging.python.org/en/latest/specifications/entry-
points>`_,
5: (0)              named ``networkx.backends`` and an optional ``networkx.backend_info`` when it
is
6: (0)              installed (not imported). This allows NetworkX to dispatch (redirect) function
calls
7: (0)              to the backend so the execution flows to the designated backend
8: (0)              implementation, similar to how plugging a charger into a socket redirects the
9: (0)              electricity to your phone. This design enhances flexibility and integration,
making
10: (0)             NetworkX more adaptable and efficient.
11: (0)             There are three main ways to use a backend after the package is installed.
12: (0)             You can set environment variables and run the exact same code you run for
13: (0)             NetworkX. You can use a keyword argument ``backend=...`` with the NetworkX
14: (0)             function. Or, you can convert the NetworkX Graph to a backend graph type and
15: (0)             call a NetworkX function supported by that backend. Environment variables
16: (0)             and backend keywords automatically convert your NetworkX Graph to the
17: (0)             backend type. Manually converting it yourself allows you to use that same
18: (0)             backend graph for more than one function call, reducing conversion time.
19: (0)             For example, you can set an environment variable before starting python to
request
20: (0)             all dispatchable functions automatically dispatch to the given backend::
21: (4)                 bash> NETWORKX_AUTOMATIC_BACKENDS=cugraph python my_networkx_script.py
22: (0)             or you can specify the backend as a kwarg::
23: (4)                 nx.betweenness_centrality(G, k=10, backend="parallel")
24: (0)             or you can convert the NetworkX Graph object ``G`` into a Graph-like
25: (0)             object specific to the backend and then pass that in the NetworkX function::
26: (4)                 H = nx_parallel.ParallelGraph(G)
27: (4)                 nx.betweenness_centrality(H, k=10)
28: (0)             How it works: You might have seen the ``@nx._dispatchable`` decorator on
29: (0)             many of the NetworkX functions in the codebase. It decorates the function
30: (0)             with code that redirects execution to the function's backend implementation.
31: (0)             The code also manages any ``backend_kwargs`` you provide to the backend
32: (0)             version of the function. The code looks for the environment variable or
33: (0)             a ``backend`` keyword argument and if found, converts the input NetworkX
34: (0)             graph to the backend format before calling the backend's version of the
35: (0)             function. If no environment variable or backend keyword are found, the
36: (0)             dispatching code checks the input graph object for an attribute
37: (0)             called ``__networkx_backend__`` which tells it which backend provides this
38: (0)             graph type. That backend's version of the function is then called.
39: (0)             The backend system relies on Python ``entry_point`` system to signal
40: (0)             NetworkX that a backend is installed (even if not imported yet). Thus no
41: (0)             code needs to be changed between running with NetworkX and running with
42: (0)             a backend to NetworkX. The attribute ``__networkx_backend__`` holds a
43: (0)             string with the name of the ``entry_point``. If none of these options
44: (0)             are being used, the decorator code simply calls the NetworkX function
45: (0)             on the NetworkX graph as usual.
46: (0)             The NetworkX library does not need to know that a backend exists for it
47: (0)             to work. So long as the backend package creates the entry_point, and
48: (0)             provides the correct interface, it will be called when the user requests
49: (0)             it using one of the three approaches described above. Some backends have
50: (0)             been working with the NetworkX developers to ensure smooth operation.
51: (0)             They are the following::
52: (0)             - `graphblas <https://github.com/python-graphblas/graphblas-algorithms>`_
53: (0)             - `cugraph <https://github.com/rapidsai/cugraph/tree/branch-24.04/python/nx-
cugraph>`_
54: (0)             - `parallel <https://github.com/networkx/nx-parallel>`_
55: (0)             - ``loopback`` is for testing purposes only and is not a real backend.
56: (0)             Note that the ``backend_name`` is e.g. ``parallel``, the package installed
57: (0)             is ``nx-parallel``, and we use ``nx_parallel`` while importing the package.
58: (0)             Creating a Custom backend
```

```
59: (0)             -------------------------
60: (0)             1.  To be a valid backend that is discoverable by NetworkX, your package must
61: (4)                 register an `entry-point
<https://packaging.python.org/en/latest/specifications/entry-points/#entry-points>`_
62: (4)                 ``networkx.backends`` in the package's metadata, with a `key pointing to
your
63: (4)                 dispatch object <https://packaging.python.org/en/latest/guides/creating-
and-discovering-plugins/#using-package-metadata>`_ .
64: (4)                 For example, if you are using ``setuptools`` to manage your backend
package,
65: (4)                 you can `add the following to your pyproject.toml file
<https://setuptools.pypa.io/en/latest/userguide/entry_point.html>`_::
66: (8)                     [project.entry-points."networkx.backends"]
67: (8)                     backend_name = "your_dispatcher_class"
68: (4)                 You can also add the ``backend_info`` entry-point. It points towards the
``get_info``
69: (4)                 function that returns all the backend information, which is then used to
build the
70: (4)                 "Additional Backend Implementation" box at the end of algorithm's
documentation
71: (4)                 page (e.g. `nx-cugraph's get_info function
<https://github.com/rapidsai/cugraph/blob/branch-24.04/python/nx-
cugraph/_nx_cugraph/__init__.py>`_)::
72: (8)                     [project.entry-points."networkx.backend_info"]
73: (8)                     backend_name = "your_get_info_function"
74: (4)                 Note that this would only work if your backend is a trusted backend of
NetworkX,
75: (4)                 and is present in the `.circleci/config.yml` and
76: (4)                 `.github/workflows/deploy-docs.yml` files in the NetworkX repository.
77: (0)             2.  The backend must create an ``nx.Graph``-like object which contains an
attribute
78: (4)                 ``__networkx_backend__`` with a value of the entry point name::
79: (8)                     class BackendGraph:
80: (12)                        __networkx_backend__ = "backend_name"
81: (12)                        ...
82: (0)             Testing the Custom backend
83: (0)             -------------------------
84: (0)             To test your custom backend, you can run the NetworkX test suite with your
backend.
85: (0)             This also ensures that the custom backend is compatible with NetworkX's API.
86: (0)             Testing Environment Setup
87: (0)             ~~~~~~~~~~~~~~~~~~~~~~~~
88: (0)             To enable automatic testing with your custom backend, follow these steps:
89: (0)             1. Set Backend Environment Variables:
90: (4)                 - ``NETWORKX_TEST_BACKEND`` : Setting this to your registered backend key
will let
91: (6)                   the NetworkX's dispatch machinery automatically convert a regular
NetworkX
92: (6)                   ``Graph``, ``DiGraph``, ``MultiGraph``, etc. to their backend
equivalents, using
93: (6)                   ``your_dispatcher_class.convert_from_nx(G, ...)`` function.
94: (4)                 - ``NETWORKX_FALLBACK_TO_NX`` (default=False) : Setting this variable to
`True` will
95: (6)                   instruct tests to use a NetworkX ``Graph`` for algorithms not
implemented by your
96: (6)                   custom backend. Setting this to `False` will only run the tests for
algorithms
97: (6)                   implemented by your custom backend and tests for other algorithms will
``xfail``.
98: (0)             2. Defining ``convert_from_nx`` and ``convert_to_nx`` methods:
99: (4)                 The arguments to ``convert_from_nx`` are:
100: (4)                - ``G`` : NetworkX Graph
101: (4)                - ``edge_attrs`` : dict, optional
102: (8)                    Dictionary mapping edge attributes to default values if missing in
``G``.
103: (8)                    If None, then no edge attributes will be converted and default may be
1.
104: (4)                - ``node_attrs``: dict, optional
105: (8)                    Dictionary mapping node attributes to default values if missing in
```

```
``G``.
106: (8)                If None, then no node attributes will be converted.
107: (4)            - ``preserve_edge_attrs`` : bool
108: (8)                Whether to preserve all edge attributes.
109: (4)            - ``preserve_node_attrs`` : bool
110: (8)                Whether to preserve all node attributes.
111: (4)            - ``preserve_graph_attrs`` : bool
112: (8)                Whether to preserve all graph attributes.
113: (4)            - ``preserve_all_attrs`` : bool
114: (8)                Whether to preserve all graph, node, and edge attributes.
115: (4)            - ``name`` : str
116: (8)                The name of the algorithm.
117: (4)            - ``graph_name`` : str
118: (8)                The name of the graph argument being converted.
119: (0)            Running Tests
120: (0)            ~~~~~~~~~~~~~
121: (0)            You can invoke NetworkX tests for your custom backend with the following
commands::
122: (4)                NETWORKX_TEST_BACKEND=<backend_name>
123: (4)                NETWORKX_FALLBACK_TO_NX=True # or False
124: (4)                pytest --pyargs networkx
125: (0)            Conversions while running tests :
126: (0)            - Convert NetworkX graphs using ``<your_dispatcher_class>.convert_from_nx(G,
...)`` into
127: (2)              the backend graph.
128: (0)            - Pass the backend graph objects to the backend implementation of the
algorithm.
129: (0)            - Convert the result back to a form expected by NetworkX tests using
130: (2)              ``<your_dispatcher_class>.convert_to_nx(result, ...)``.
131: (0)            Notes
132: (0)            ~~~~~
133: (0)            -   Dispatchable algorithms that are not implemented by the backend
134: (4)                will cause a ``pytest.xfail``, giving some indication that not all
135: (4)                tests are running, while avoiding causing an explicit failure.
136: (0)            -   If a backend only partially implements some algorithms, it can define
137: (4)                a ``can_run(name, args, kwargs)`` function that returns True or False
138: (4)                indicating whether it can run the algorithm with the given arguments.
139: (4)                It may also return a string indicating why the algorithm can't be run;
140: (4)                this string may be used in the future to give helpful info to the user.
141: (0)            -   A backend may also define ``should_run(name, args, kwargs)`` that is
similar
142: (4)                to ``can_run``, but answers whether the backend *should* be run
(converting
143: (4)                if necessary). Like ``can_run``, it receives the original arguments so it
144: (4)                can decide whether it should be run by inspecting the arguments.
``can_run``
145: (4)                runs before ``should_run``, so ``should_run`` may assume ``can_run`` is
True.
146: (4)                If not implemented by the backend, ``can_run`` and ``should_run`` are
147: (4)                assumed to always return True if the backend implements the algorithm.
148: (0)            -   A special ``on_start_tests(items)`` function may be defined by the
backend.
149: (4)                It will be called with the list of NetworkX tests discovered. Each item
150: (4)                is a test object that can be marked as xfail if the backend does not
support
151: (4)                the test using ``item.add_marker(pytest.mark.xfail(reason=...))``.
152: (0)            -   A backend graph instance may have a ``G.__networkx_cache__`` dict to
enable
153: (4)                caching, and care should be taken to clear the cache when appropriate.
154: (0)            """

"default"})
282: (8)                    with 0 and 1 giving the position in the signature function for graph
objects.
283: (8)                    When edge_attrs is a dict, keys are keyword names and values are
defaults.
284: (8)                    The class attributes are used to allow backends to run networkx tests.
285: (8)                    For example: `PYTHONPATH=. pytest --backend graphblas --fallback-to-
nx`
286: (8)                    Future work: add configuration to control these.
287: (8)                    Parameters
```

```
                    ----------
                    func : callable, optional
                        The function to be decorated. If ``func`` is not provided, returns
a
                        partial object that can be used to decorate a function later. If
``func``
                        is provided, returns a new callable object that dispatches to a
backend
                        algorithm based on input graph types.
                    name : str, optional
                        The name of the algorithm to use for dispatching. If not provided,
                        the name of ``func`` will be used. ``name`` is useful to avoid
name
                        conflicts, as all dispatched algorithms live in a single
namespace.
                        For example, ``tournament.is_strongly_connected`` had a name
conflict
                        with the standard ``nx.is_strongly_connected``, so we used
                        ``@_dispatchable(name="tournament_is_strongly_connected")``.
                    graphs : str or dict or None, default "G"
                        If a string, the parameter name of the graph, which must be the
first
                        argument of the wrapped function. If more than one graph is
required
                        for the algorithm (or if the graph is not the first argument),
provide
                        a dict of parameter name to argument position for each graph
argument.
                        For example, ``@_dispatchable(graphs={"G": 0, "auxiliary?": 4})``
                        indicates the 0th parameter ``G`` of the function is a required
graph,
                        and the 4th parameter ``auxiliary`` is an optional graph.
                        To indicate an argument is a list of graphs, do e.g. ``"
[graphs]"``.
                        Use ``graphs=None`` if *no* arguments are NetworkX graphs such as
for
                        graph generators, readers, and conversion functions.
                    edge_attrs : str or dict, optional
                        ``edge_attrs`` holds information about edge attribute arguments
                        and default values for those edge attributes.
                        If a string, ``edge_attrs`` holds the function argument name that
                        indicates a single edge attribute to include in the converted
graph.
                        The default value for this attribute is 1. To indicate that an
argument
                        is a list of attributes (all with default value 1), use e.g. ``"
[attrs]"``.
                        If a dict, ``edge_attrs`` holds a dict keyed by argument names,
with
                        values that are either the default value or, if a string, the
argument
                        name that indicates the default value.
                    node_attrs : str or dict, optional
                        Like ``edge_attrs``, but for node attributes.
                    preserve_edge_attrs : bool or str or dict, optional
                        For bool, whether to preserve all edge attributes.
                        For str, the parameter name that may indicate (with ``True`` or a
                        callable argument) whether all edge attributes should be preserved
                        when converting.
                        For dict of ``{graph_name: {attr: default}}``, indicate pre-
determined
                        edge attributes (and defaults) to preserve for input graphs.
                    preserve_node_attrs : bool or str or dict, optional
                        Like ``preserve_edge_attrs``, but for node attributes.
                    preserve_graph_attrs : bool or set
                        For bool, whether to preserve all graph attributes.
                        For set, which input graph arguments to preserve graph attributes.
                    preserve_all_attrs : bool
                        Whether to preserve all edge, node and graph attributes.
```

```

File 548 - configs.py:

```
1: (0)              import collections
2: (0)              import os
3: (0)              import typing
4: (0)              from dataclasses import dataclass
5: (0)              __all__ = ["Config", "config"]
6: (0)              @dataclass(init=False, eq=False, slots=True, kw_only=True, match_args=False)
7: (0)              class Config:
8: (4)                  """The base class for NetworkX configuration.
9: (4)                  There are two ways to use this to create configurations. The first is to
10: (4)                 simply pass the initial configuration as keyword arguments to ``Config``:
11: (4)                 >>> cfg = Config(eggs=1, spam=5)
12: (4)                 >>> cfg
13: (4)                 Config(eggs=1, spam=5)
14: (4)                 The second--and preferred--way is to subclass ``Config`` with docs and
annotations.
15: (4)                 >>> class MyConfig(Config):
16: (4)                 ...     '''Breakfast!'''
17: (4)                 ...
18: (4)                 ...     eggs: int
19: (4)                 ...     spam: int
20: (4)                 ...
21: (4)                 ...     def _check_config(self, key, value):
22: (4)                 ...         assert isinstance(value, int) and value >= 0
23: (4)                 >>> cfg = MyConfig(eggs=1, spam=5)
24: (4)                 Once defined, config items may be modified, but can't be added or deleted
by default.
25: (4)                 ``Config`` is a ``Mapping``, and can get and set configs via attributes or
brackets:
26: (4)                 >>> cfg.eggs = 2
27: (4)                 >>> cfg.eggs
28: (4)                 2
29: (4)                 >>> cfg["spam"] = 42
30: (4)                 >>> cfg["spam"]
31: (4)                 42
32: (4)                 Subclasses may also define ``_check_config`` (as done in the example
above)
```

```
(4)                 to ensure the value being assigned is valid:
(4)                 >>> cfg.spam = -1
(4)                 Traceback (most recent call last):
(8)                     ...
(4)                 AssertionError
(4)                 If a more flexible configuration object is needed that allows adding and deleting
(4)                 configurations, then pass ``strict=False`` when defining the subclass:
(4)                 >>> class FlexibleConfig(Config, strict=False):
(4)                 ...     default_greeting: str = "Hello"

configurations:
138: (4)                >>> nx.config.backend_priority == nx.config["backend_priority"]
139: (4)                True
140: (4)                Parameters
141: (4)                ----------
142: (4)                backend_priority : list of backend names
143: (8)                    Enable automatic conversion of graphs to backend graphs for algorithms
144: (8)                    implemented by the backend. Priority is given to backends listed
earlier.
145: (8)                    Default is empty list.
146: (4)                backends : Config mapping of backend names to backend Config
147: (8)                    The keys of the Config mapping are names of all installed NetworkX
backends,
148: (8)                    and the values are their configurations as Config mappings.
149: (4)                cache_converted_graphs : bool
150: (8)                    If True, then save converted graphs to the cache of the input graph.
Graph
151: (8)                    conversion may occur when automatically using a backend from
`backend_priority`
152: (8)                    or when using the `backend=` keyword argument to a function call.
Caching can
153: (8)                    improve performance by avoiding repeated conversions, but it uses more
memory.
154: (8)                    Care should be taken to not manually mutate a graph that has cached
```

```
graphs; for
155: (8)                    example, ``G[u][v][k] = val`` changes the graph, but does not clear
the cache.
156: (8)                    Using methods such as ``G.add_edge(u, v, weight=val)`` will clear the
cache to
157: (8)                    keep it consistent. ``G.__networkx_cache__.clear()`` manually clears
the cache.
158: (8)                    Default is False.
159: (4)                Notes
160: (4)                -----
161: (4)                Environment variables may be used to control some default configurations:
162: (4)                - NETWORKX_BACKEND_PRIORITY: set `backend_priority` from comma-separated
names.
163: (4)                - NETWORKX_CACHE_CONVERTED_GRAPHS: set `cache_converted_graphs` to True if
nonempty.
164: (4)                This is a global configuration. Use with caution when using from multiple
threads.
165: (4)                """

 113: (4)                 Notes
 114: (4)                 -----
 115: (4)                 Note that this decorator solves the problem when a path argument is
 116: (4)                 specified as a string, but it does not handle the situation when the
 117: (4)                 function wants to accept a default of None (and then handle it).
 118: (4)                 Here is an example of how to handle this case::
 119: (6)                   @open_file("path")
 120: (6)                   def some_function(arg1, arg2, path=None):
 121: (10)                      if path is None:
 122: (14)                          fobj = tempfile.NamedTemporaryFile(delete=False)
 123: (10)                      else:
 124: (14)                          fobj = path
 125: (10)                      try:
 126: (14)                          fobj.write("blah")
 127: (10)                      finally:
 128: (14)                          if path is None:
 129: (18)                              fobj.close()
 130: (4)                 Normally, we'd want to use "with" to ensure that fobj gets closed.
 131: (4)                 However, the decorator will make `path` a file object for us,
 132: (4)                 and using "with" would undesirably close that file object.
 133: (4)                 Instead, we use a try block, as shown above.
 134: (4)                 When we exit the function, fobj will be closed, if it should be, by the
decorator.
 135: (4)                 """

(4)                 ----------
(4)                 random_state_argument : string or int
(8)                     The name of the argument or the index of the argument in args that is
(8)                     to be converted to the random.Random instance or
numpy.random.RandomState
(8)                     instance that mimics basic methods of random.Random.
(4)                 Returns
(4)                 -------
(4)                 _random_state : function
(8)                     Function whose random_state_argument is converted to a Random
instance.
(4)                 Examples
(4)                 --------
(4)                 Decorate functions like this::
(7)                    @py_random_state("random_state")
(7)                    def random_float(random_state=None):
(11)                       return random_state.rand()
(7)                    @py_random_state(0)
(7)                    def random_float(rng=None):
(11)                       return rng.rand()
(7)                    @py_random_state(1)
(7)                    def random_array(dims, seed=12345):
(11)                       return seed.rand(*dims)
(4)                 See Also
(4)                 --------
(4)                 np_random_state
(4)                 """
```

```
    return argmap(create_py_random_state, random_state_argument)
class argmap:
    """A decorator to apply a map to arguments before calling the function
    This class provides a decorator that maps (transforms) arguments of the function
    before the function is called. Thus for example, we have similar code
    in many functions to determine whether an argument is the number of nodes
    to be created, or a list of nodes to be handled. The decorator provides
    the code to accept either -- transforming the indicated argument into a
    list of nodes before the actual function is called.
    This decorator class allows us to process single or multiple arguments.
    The arguments to be processed can be specified by string, naming the argument,
    or by index, specifying the item in the args list.
    Parameters
    ----------
    func : callable
        The function to apply to arguments
    *args : iterable of (int, str or tuple)
        A list of parameters, specified either as strings (their names), ints
        (numerical indices) or tuples, which may contain ints, strings, and
        (recursively) tuples. Each indicates which parameters the decorator
        should map. Tuples indicate that the map function takes (and returns)
        multiple parameters in the same order and nested structure as indicated
        here.
    try_finally : bool (default: False)
        When True, wrap the function call in a try-finally block with code
        for the finally block created by `func`. This is used when the map
        function constructs an object (like a file handle) that requires
        post-processing (like closing).
        Note: try_finally decorators cannot be used to decorate generator
        functions.
    Examples
    --------
    Most of these examples use `@argmap(...)` to apply the decorator to
    the function defined on the next line.
    In the NetworkX codebase however, `argmap` is used within a function to
    construct a decorator. That is, the decorator defines a mapping function
    and then uses `argmap` to build and return a decorated function.
    A simple example is a decorator that specifies which currency to report money.
    The decorator (named `convert_to`) would be used like::
        @convert_to("US_Dollars", "income")
        def show_me_the_money(name, income):
            print(f"{name} : {income}")
    And the code to create the decorator might be::
        def convert_to(currency, which_arg):
            def _convert(amount):
                if amount.currency != currency:
                    amount = amount.to_currency(currency)
                return amount
            return argmap(_convert, which_arg)
    Despite this common idiom for argmap, most of the following examples
    use the `@argmap(...)` idiom to save space.
    Here's an example use of argmap to sum the elements of two of the functions
    arguments. The decorated function::
        @argmap(sum, "xlist", "zlist")
        def foo(xlist, y, zlist):
            return xlist - y + zlist
    is syntactic sugar for::
        def foo(xlist, y, zlist):
            x = sum(xlist)
            z = sum(zlist)
            return x - y + z
    and is equivalent to (using argument indexes)::
        @argmap(sum, "xlist", 2)
        def foo(xlist, y, zlist):
```

```
332: (12)                        return xlist - y + zlist
333: (4)                 or::
334: (8)                     @argmap(sum, "zlist", 0)
335: (8)                     def foo(xlist, y, zlist):
336: (12)                        return xlist - y + zlist
337: (4)                 Transforming functions can be applied to multiple arguments, such as::
338: (8)                     def swap(x, y):
339: (12)                        return y, x
340: (8)                     @argmap(swap, ("a", "b")):
341: (8)                     def foo(a, b, c):
342: (12)                        return a / b * c
343: (4)                 is equivalent to::
344: (8)                     def foo(a, b, c):
345: (12)                        a, b = swap(a, b)
346: (12)                        return a / b * c
347: (4)                 More generally, the applied arguments can be nested tuples of strings or
ints.
348: (4)                 The syntax `@argmap(some_func, ("a", ("b", "c")))` would expect
`some_func` to
349: (4)                 accept 2 inputs with the second expected to be a 2-tuple. It should then
return
350: (4)                 2 outputs with the second a 2-tuple. The returns values would replace
input "a"
351: (4)                 "b" and "c" respectively. Similarly for `@argmap(some_func, (0, ("b",
2)))`.
352: (4)                 Also, note that an index larger than the number of named parameters is
allowed
353: (4)                 for variadic functions. For example::
354: (8)                     def double(a):
355: (12)                        return 2 * a
356: (8)                     @argmap(double, 3)
357: (8)                     def overflow(a, *args):
358: (12)                        return a, args
359: (8)                     print(overflow(1, 2, 3, 4, 5, 6))  # output is 1, (2, 3, 8, 5, 6)
360: (4)                 **Try Finally**
361: (4)                 Additionally, this `argmap` class can be used to create a decorator that
362: (4)                 initiates a try...finally block. The decorator must be written to return
363: (4)                 both the transformed argument and a closing function.
364: (4)                 This feature was included to enable the `open_file` decorator which might
365: (4)                 need to close the file or not depending on whether it had to open that
file.
366: (4)                 This feature uses the keyword-only `try_finally` argument to `@argmap`.
367: (4)                 For example this map opens a file and then makes sure it is closed::
368: (8)                     def open_file(fn):
369: (12)                        f = open(fn)
370: (12)                        return f, lambda: f.close()
371: (4)                 The decorator applies that to the function `foo`::
372: (8)                     @argmap(open_file, "file", try_finally=True)
373: (8)                     def foo(file):
374: (12)                        print(file.read())
375: (4)                 is syntactic sugar for::
376: (8)                     def foo(file):
377: (12)                        file, close_file = open_file(file)
378: (12)                        try:
379: (16)                            print(file.read())
380: (12)                        finally:
381: (16)                            close_file()
382: (4)                 and is equivalent to (using indexes)::
383: (8)                     @argmap(open_file, 0, try_finally=True)
384: (8)                     def foo(file):
385: (12)                        print(file.read())
386: (4)                 Here's an example of the try_finally feature used to create a decorator::
387: (8)                     def my_closing_decorator(which_arg):
388: (12)                        def _opener(path):
389: (16)                            if path is None:
390: (20)                                path = open(path)
391: (20)                                fclose = path.close
392: (16)                            else:
393: (20)                                fclose = lambda: None
```

```
            return path, fclose
        return argmap(_opener, which_arg, try_finally=True)
which can then be used as::
    @my_closing_decorator("file")
    def fancy_reader(file=None):
        print(file.read())
Decorators with try_finally = True cannot be used with generator functions,
because the `finally` block is evaluated before the generator is exhausted::
    @argmap(open_file, "file", try_finally=True)
    def file_to_lines(file):
        for line in file.readlines():
            yield line
is equivalent to::
    def file_to_lines_wrapped(file):
        for line in file.readlines():
            yield line
    def file_to_lines_wrapper(file):
        try:
            file = open_file(file)
            return file_to_lines_wrapped(file)
        finally:
            file.close()
which behaves similarly to::
    def file_to_lines_whoops(file):
        file = open_file(file)
        file.close()
        for line in file.readlines():
            yield line
because the `finally` block of `file_to_lines_wrapper` is executed before
the caller has a chance to exhaust the iterator.
Notes
-----
An object of this class is callable and intended to be used when
defining a decorator. Generally, a decorator takes a function as input
and constructs a function as output. Specifically, an `argmap` object
returns the input function decorated/wrapped so that specified arguments
are mapped (transformed) to new values before the decorated function is called.
As an overview, the argmap object returns a new function with all the
dunder values of the original function (like `__doc__`, `__name__`, etc).
Code for this decorated function is built based on the original function's
signature. It starts by mapping the input arguments to potentially new
values. Then it calls the decorated function with these new values in place
of the indicated arguments that have been mapped. The return value of the
original function is then returned. This new function is the function that
is actually called by the user.
Three additional features are provided.
    1) The code is lazily compiled. That is, the new function is returned
    as an object without the code compiled, but with all information
    needed so it can be compiled upon it's first invocation. This saves
    time on import at the cost of additional time on the first call of
    the function. Subsequent calls are then just as fast as normal.
    2) If the "try_finally" keyword-only argument is True, a try block
    follows each mapped argument, matched on the other side of the wrapped
    call, by a finally block closing that mapping.  We expect func to return
    a 2-tuple: the mapped value and a function to be called in the finally
    clause.  This feature was included so the `open_file` decorator could
    provide a file handle to the decorated function and close the file handle
    after the function call. It even keeps track of whether to close the file
    handle or not based on whether it had to open the file or the input was
    already open. So, the decorated function does not need to include any
    code to open or close files.
```

```
(8)                 3) The maps applied can process multiple arguments. For example,
(8)                 you could swap two arguments using a mapping, or transform
(8)                 them to their sum and their difference. This was included to allow
(8)                 a decorator in the `quality.py` module that checks that an input
(8)                 `partition` is a valid partition of the nodes of the input graph `G`.
(8)                 In this example, the map has inputs `(G, partition)`. After checking
(8)                 for a valid partition, the map either raises an exception or leaves
(8)                 the inputs unchanged. Thus many functions that make this check can
(8)                 use the decorator rather than copy the checking code into each
function.
(8)                 More complicated nested argument structures are described below.
(4)             The remaining notes describe the code structure and methods for this
(4)             class in broad terms to aid in understanding how to use it.
(4)             Instantiating an `argmap` object simply stores the mapping function and
(4)             the input identifiers of which arguments to map. The resulting decorator
(4)             is ready to use this map to decorate any function. Calling that object
(4)             (`argmap.__call__`, but usually done via `@my_decorator`) a lazily
(4)             compiled thin wrapper of the decorated function is constructed,
(4)             wrapped with the necessary function dunder attributes like `__doc__`
(4)             and `__name__`. That thinly wrapped function is returned as the
(4)             decorated function. When that decorated function is called, the thin
(4)             wrapper of code calls `argmap._lazy_compile` which compiles the decorated
(4)             function (using `argmap.compile`) and replaces the code of the thin
(4)             wrapper with the newly compiled code. This saves the compilation step
(4)             every import of networkx, at the cost of compiling upon the first call
(4)             to the decorated function.
(4)             When the decorated function is compiled, the code is recursively assembled
(4)             using the `argmap.assemble` method. The recursive nature is needed in
(4)             case of nested decorators. The result of the assembly is a number of
(4)             useful objects.
(6)               sig : the function signature of the original decorated function as
(10)                  constructed by :func:`argmap.signature`. This is constructed
(10)                  using `inspect.signature` but enhanced with attribute
(10)                  strings `sig_def` and `sig_call`, and other information
(10)                  specific to mapping arguments of this function.
(10)                  This information is used to construct a string of code defining
(10)                  the new decorated function.
(6)               wrapped_name : a unique internally used name constructed by argmap
(10)                  for the decorated function.
(6)               functions : a dict of the functions used inside the code of this
(10)                  decorated function, to be used as `globals` in `exec`.
(10)                  This dict is recursively updated to allow for nested decorating.
(6)               mapblock : code (as a list of strings) to map the incoming argument
(10)                  values to their mapped values.
(6)               finallys : code (as a list of strings) to provide the possibly nested
(10)                  set of finally clauses if needed.
(6)               mutable_args : a bool indicating whether the `sig.args` tuple should be
(10)                  converted to a list so mutation can occur.
(4)             After this recursive assembly process, the `argmap.compile` method
(4)             constructs code (as strings) to convert the tuple `sig.args` to a list
(4)             if needed. It joins the defining code with appropriate indents and
(4)             compiles the result.  Finally, this code is evaluated and the original
(4)             wrapper's implementation is replaced with the compiled version (see
(4)             `argmap._lazy_compile` for more details).
(4)             Other `argmap` methods include `_name` and `_count` which allow internally
(4)             generated names to be unique within a python session.
(4)             The methods `_flatten` and `_indent` process the nested lists of strings
(4)             into properly indented python code ready to be compiled.
(4)             More complicated nested tuples of arguments also allowed though
(4)             usually not used. For the simple 2 argument case, the argmap
(4)             input ("a", "b") implies the mapping function will take 2 arguments
(4)             and return a 2-tuple of mapped values. A more complicated example
(4)             with argmap input `("a", ("b", "c"))` requires the mapping function
(4)             take 2 inputs, with the second being a 2-tuple. It then must output
(4)             the 3 mapped values in the same nested structure `(newa, (newb, newc))`.
(4)             This level of generality is not often needed, but was convenient
(4)             to implement when handling the multiple arguments.
(4)             See Also

    """
    def __init__(self, func, *args, try_finally=False):
        self._func = func
        self._args = args
        self._finally = try_finally
    @staticmethod
    def _lazy_compile(func):
        """Compile the source of a wrapped function
        Assemble and compile the decorated function, and intrusively replace its
        code with the compiled version's.  The thinly wrapped function becomes
        the decorated function.
        Parameters
        ----------
        func : callable
            A function returned by argmap.__call__ which is in the process
            of being called for the first time.
        Returns
        -------
        func : callable
            The same function, with a new __code__ object.
        Notes
        -----
        It was observed in NetworkX issue #4732 [1] that the import time of
        NetworkX was significantly bloated by the use of decorators: over half
        of the import time was being spent decorating functions.  This was
        somewhat improved by a change made to the `decorator` library, at the
        cost of a relatively heavy-weight call to `inspect.Signature.bind`
        for each call to the decorated function.
        The workaround we arrived at is to do minimal work at the time of
        decoration.  When the decorated function is called for the first time,
        we compile a function with the same function signature as the wrapped
        function.  The resulting decorated function is faster than one made by
        the `decorator` library, so that the overhead of the first call is
        'paid off' after a small number of calls.

wrapping f.
(8)                     If `f` has multiple argmap decorators, we recursively assemble the
stack of
(8)                     decorators into a single flattened function.
(8)                     This method is part of the `compile` method's process yet separated
(8)                     from that method to allow recursive processing. The outputs are
(8)                     strings, dictionaries and lists that collect needed info to
(8)                     flatten any nested argmap-decoration.
(8)                     Parameters
(8)                     ----------
(8)                     f : callable
(12)                        The function to be decorated.  If f is argmapped, we assemble it.
(8)                     Returns
(8)                     -------
(8)                     sig : argmap.Signature
(12)                        The function signature as an `argmap.Signature` object.
(8)                     wrapped_name : str
(12)                        The mangled name used to represent the wrapped function in the
code
(12)                        being assembled.
(8)                     functions : dict
(12)                        A dictionary mapping id(g) -> (mangled_name(g), g) for functions g
(12)                        referred to in the code being assembled. These need to be present
(12)                        in the ``globals`` scope of ``exec`` when defining the decorated
(12)                        function.
(8)                     mapblock : list of lists and/or strings
(12)                        Code that implements mapping of parameters including any try
blocks
(12)                        if needed. This code will precede the decorated function call.
(8)                     finallys : list of lists and/or strings
(12)                        Code that implements the finally blocks to post-process the
(12)                        arguments (usually close any files if needed) after the
(12)                        decorated function is called.
(8)                     mutable_args : bool
(12)                        True if the decorator needs to modify positional arguments
(12)                        via their indices. The compile method then turns the argument
```

```
713: (12)                        tuple into a list so that the arguments can be modified.
714: (8)                    """

(8)                     Notes
(8)                     -----
(8)                     The Signature is a namedtuple with names:
(12)                        name : a unique version of the name of the decorated function
(12)                        signature : the inspect.signature of the decorated function
(12)                        def_sig : a string used as code to define the new function
(12)                        call_sig : a string used as code to call the decorated function
(12)                        names : a dict keyed by argument name and index to the argument's
name
(12)                        n_positional : the number of positional arguments in the signature
(12)                        args : the name of the VAR_POSITIONAL argument if any, i.e.
\*theseargs
(12)                        kwargs : the name of the VAR_KEYWORDS argument if any, i.e.
\*\*kwargs
(8)                     These named attributes of the signature are used in `assemble` and
`compile`
(8)                     to construct a string of source code for the decorated function.
(8)                     """

File 551 - mapped_queue.py:

```
1: (0)              """Priority queue class with updatable priorities.
2: (0)              """
3: (0)              import heapq
4: (0)              __all__ = ["MappedQueue"]
5: (0)              class _HeapElement:
6: (4)                  """This proxy class separates the heap element from its priority.
7: (4)                  The idea is that using a 2-tuple (priority, element) works
8: (4)                  for sorting, but not for dict lookup because priorities are
9: (4)                  often floating point values so round-off can mess up equality.
10: (4)                 So, we need inequalities to look at the priority (for sorting)
11: (4)                 and equality (and hash) to look at the element to enable
12: (4)                 updates to the priority.
13: (4)                 Unfortunately, this class can be tricky to work with if you forget that
14: (4)                 `__lt__` compares the priority while `__eq__` compares the element.
15: (4)                 In `greedy_modularity_communities()` the following code is
16: (4)                 used to check that two _HeapElements differ in either element or priority:
17: (8)                     if d_oldmax != row_max or d_oldmax.priority != row_max.priority:
18: (4)                 If the priorities are the same, this implementation uses the element
19: (4)                 as a tiebreaker. This provides compatibility with older systems that
20: (4)                 use tuples to combine priority and elements.
21: (4)                 """

69: (8)                     return f"_HeapElement({self.priority}, {self.element})"
70: (0)             class MappedQueue:
71: (4)                 """The MappedQueue class implements a min-heap with removal and update-
priority.
72: (4)                 The min heap uses heapq as well as custom written _siftup and _siftdown
73: (4)                 methods to allow the heap positions to be tracked by an additional dict
74: (4)                 keyed by element to position. The smallest element can be popped in O(1)
time,
75: (4)                 new elements can be pushed in O(log n) time, and any element can be
removed
76: (4)                 or updated in O(log n) time. The queue cannot contain duplicate elements
77: (4)                 and an attempt to push an element already in the queue will have no
effect.
78: (4)                 MappedQueue complements the heapq package from the python standard
79: (4)                 library. While MappedQueue is designed for maximum compatibility with
80: (4)                 heapq, it adds element removal, lookup, and priority update.
81: (4)                 Parameters
82: (4)                 ----------
83: (4)                 data : dict or iterable
84: (4)                 Examples
85: (4)                 --------
86: (4)                 A `MappedQueue` can be created empty, or optionally, given a dictionary
87: (4)                 of initial elements and priorities.  The methods `push`, `pop`,
88: (4)                 `remove`, and `update` operate on the queue.
89: (4)                 >>> colors_nm = {"red": 665, "blue": 470, "green": 550}
90: (4)                 >>> q = MappedQueue(colors_nm)
91: (4)                 >>> q.remove("red")

 118: (4)               This is most useful for "peeking" at an arbitrary element of a set,
 119: (4)               but can be used for any list, dictionary, etc., as well.
 120: (4)               Parameters
 121: (4)               ----------
 122: (4)               iterable : `abc.collections.Iterable` instance
 123: (8)                   Any object that implements ``__iter__``, e.g. set, dict, list, tuple,
 124: (8)                   etc.
 125: (4)               Returns
 126: (4)               -------
 127: (4)               The object that results from ``next(iter(iterable))``
 128: (4)               Raises
 129: (4)               ------
 130: (4)               ValueError
 131: (8)                   If `iterable` is an iterator (because the current implementation of
 132: (8)                   this function would consume an element from the iterator).
```

```
(4)                 Examples
(4)                 --------
(4)                 Arbitrary elements from common Iterable objects:
(4)                 >>> nx.utils.arbitrary_element([1, 2, 3])  # list
(4)                 1
(4)                 >>> nx.utils.arbitrary_element((1, 2, 3))  # tuple
(4)                 1
(4)                 >>> nx.utils.arbitrary_element({1, 2, 3})  # set
(4)                 1
(4)                 >>> d = {k: v for k, v in zip([1, 2, 3], [3, 2, 1])}
(4)                 >>> nx.utils.arbitrary_element(d)  # dict_keys
(4)                 1
(4)                 >>> nx.utils.arbitrary_element(d.values())  # dict values
(4)                 3
(4)                 `str` is also an Iterable:
(4)                 >>> nx.utils.arbitrary_element("hello")
(4)                 'h'
(4)                 :exc:`ValueError` is raised if `iterable` is an iterator:
(4)                 >>> iterator = iter([1, 2, 3])  # Iterator, *not* Iterable
(4)                 >>> nx.utils.arbitrary_element(iterator)
(4)                 Traceback (most recent call last):
(8)                     ...
(4)                 ValueError: cannot return an arbitrary item from an iterator
(4)                 Notes
(4)                 -----
(4)                 This function does not return a *random* element. If `iterable` is
(4)                 ordered, sequential calls will return the same value::
(8)                     >>> l = [1, 2, 3]
(8)                     >>> nx.utils.arbitrary_element(l)
(8)                     1
(8)                     >>> nx.utils.arbitrary_element(l)
(8)                     1
(4)                 """

318: (4)                ----------
319: (4)                random_state : int or random number generator or None (default=None)
320: (8)                    - If int, return a `random.Random` instance set with seed=int.
321: (8)                    - If `random.Random` instance, return it.
322: (8)                    - If None or the `np.random` package, return the global random number
323: (10)                     generator used by `np.random`.
324: (8)                    - If an `np.random.Generator` instance, or the `np.random` package, or
325: (10)                     the global numpy random number generator, then return it.
326: (10)                     wrapped in a `PythonRandomViaNumpyBits` class.
327: (8)                    - If a `PythonRandomViaNumpyBits` instance, return it.
328: (8)                    - If a `PythonRandomInterface` instance, return it.
329: (8)                    - If a `np.random.RandomState` instance and not the global numpy
default,
330: (10)                     return it wrapped in `PythonRandomInterface` for backward bit-stream
```

```
(10)                    matching with legacy code.
(4)                Notes
(4)                -----
(4)                - A diagram intending to illustrate the relationships behind our support
(6)                  for numpy random numbers is called
(6)                  `NetworkX Numpy Random Numbers
<https://excalidraw.com/#room=b5303f2b03d3af7ccc6a,e5ZDIWdWWCTTsg8OqoRvPA>`_.
(4)                - More discussion about this support also appears in
(6)                  `gh-6869#comment
<https://github.com/networkx/networkx/pull/6869#issuecomment-1944799534>`_.
(4)                - Wrappers of numpy.random number generators allow them to mimic the
Python random
(6)                  number generation algorithms. For example, Python can create arbitrarily
large
(6)                  random ints, and the wrappers use Numpy bit-streams with CPython's
random module
(6)                  to choose arbitrarily large random integers too.
(4)                - We provide two wrapper classes:
(6)                  `PythonRandomViaNumpyBits` is usually what you want and is always used
for
(6)                  `np.Generator` instances. But for users who need to recreate random
numbers
(6)                  produced in NetworkX 3.2 or earlier, we maintain the
`PythonRandomInterface`
(6)                  wrapper as well. We use it only used if passed a (non-default)
`np.RandomState`
(6)                  instance pre-initialized from a seed. Otherwise the newer wrapper is
used.
