        array([0., 0., 0.])
        >>> coef = hermefromroots((-1j, 1j))
        >>> hermeval((-1j, 1j), coef)
        array([0.+0.j, 0.+0.j])
        """
        return pu._fromroots(hermeline, hermemul, roots)
def hermeadd(c1, c2):
    """
    Add one Hermite series to another.
    Returns the sum of two Hermite series `c1` + `c2`. The arguments
    are sequences of coefficients ordered from lowest order term to
    highest, i.e., [1,2,3] represents the series ``P_0 + 2*P_1 + 3*P_2``.
    Parameters
    -----
    c1, c2 : array_like
        1-D arrays of Hermite series coefficients ordered from low to
        high.
    Returns
    -----
    out : ndarray
        Array representing the Hermite series of their sum.
    See Also
    -----
    hermesub, hermemulx, hermemul, hermediv, hermepow
    Notes
    -----
    Unlike multiplication, division, etc., the sum of two Hermite series
    is a Hermite series (without having to "reproject" the result onto
    the basis set) so addition, just like that of "standard" polynomials,
    is simply "component-wise."
    Examples
    -----
    >>> from numpy.polynomial.hermite_e import hermeadd
    >>> hermeadd([1, 2, 3], [1, 2, 3, 4])
    array([2., 4., 6., 4.])
    """

575: (4)             hermeder
576: (4)             Notes

```

```

577: (4)      -----
578: (4)      Note that the result of each integration is *multiplied* by `scl`.
579: (4)      Why is this important to note? Say one is making a linear change of
580: (4)      variable :math:`u = ax + b` in an integral relative to `x`. Then
581: (4)      :math:`dx = du/a`, so one will need to set `scl` equal to
582: (4)      :math:`1/a` - perhaps not what one would have first thought.
583: (4)      Also note that, in general, the result of integrating a C-series needs
584: (4)      to be "reprojected" onto the C-series basis set. Thus, typically,
585: (4)      the result of this function is "unintuitive," albeit correct; see
586: (4)      Examples section below.
587: (4)      Examples
588: (4)      -----
589: (4)      >>> from numpy.polynomial.hermite_e import hermeint

637: (4)          """
638: (4)          Evaluate an HermiteE series at points x.
639: (4)          If `c` is of length `n + 1`, this function returns the value:
640: (4)          .. math:: p(x) = c_0 * He_0(x) + c_1 * He_1(x) + \dots + c_n * He_n(x)
641: (4)          The parameter `x` is converted to an array only if it is a tuple or a
642: (4)          list, otherwise it is treated as a scalar. In either case, either `x`
643: (4)          or its elements must support multiplication and addition both with

```

```

644: (4)           themselves and with the elements of `c`.
645: (4)           If `c` is a 1-D array, then `p(x)` will have the same shape as `x`. If
646: (4)           `c` is multidimensional, then the shape of the result depends on the
647: (4)           value of `tensor`. If `tensor` is true the shape will be c.shape[1:] +
648: (4)           x.shape. If `tensor` is false the shape will be c.shape[1:].
649: (4)           Note that scalars have shape ().
650: (4)           Trailing zeros in the coefficients will be used in the evaluation, so
651: (4)           they should be avoided if efficiency is a concern.
652: (4)           Parameters
653: (4)           -----
654: (4)           x : array_like, compatible object
655: (8)             If `x` is a list or tuple, it is converted to an ndarray, otherwise
656: (8)             it is left unchanged and treated as a scalar. In either case, `x`
657: (8)             or its elements must support addition and multiplication with
658: (8)             with themselves and with the elements of `c`.
659: (4)           c : array_like
660: (8)             Array of coefficients ordered so that the coefficients for terms of
661: (8)             degree n are contained in c[n]. If `c` is multidimensional the
662: (8)             remaining indices enumerate multiple polynomials. In the two
663: (8)             dimensional case the coefficients may be thought of as stored in
664: (8)             the columns of `c`.
665: (4)           tensor : boolean, optional
666: (8)             If True, the shape of the coefficient array is extended with ones
667: (8)             on the right, one for each dimension of `x`. Scalars have dimension 0
668: (8)             for this action. The result is that every column of coefficients in
669: (8)             `c` is evaluated for every element of `x`. If False, `x` is broadcast
670: (8)             over the columns of `c` for the evaluation. This keyword is useful
671: (8)             when `c` is multidimensional. The default value is True.

def hermevander(x, deg):
    """Pseudo-Vandermonde matrix of given degree.
    Returns the pseudo-Vandermonde matrix of degree `deg` and sample points
    `x`. The pseudo-Vandermonde matrix is defined by
    .. math:: V[..., i] = He_i(x),
    where `0 <= i <= deg`. The leading indices of `V` index the elements of
    `x` and the last index is the degree of the HermiteE polynomial.
    If `c` is a 1-D array of coefficients of length `n + 1` and `V` is the
    array ``V = hermevander(x, n)``, then ``np.dot(V, c)`` and
    ``hermeval(x, c)`` are the same up to roundoff. This equivalence is
    useful both for least squares fitting and for the evaluation of a large
    number of HermiteE series of the same degree and sample points.
    Parameters
    -----
    x : array_like
        Array of points. The dtype is converted to float64 or complex128
        depending on whether any of the elements are complex. If `x` is
        scalar it is converted to a 1-D array.
    deg : int
        Degree of the resulting matrix.
    Returns
    -----
    vander : ndarray
        The pseudo-Vandermonde matrix. The shape of the returned matrix is
        ``x.shape + (deg + 1,)``, where The last index is the degree of the
        corresponding HermiteE polynomial. The dtype will be the same as
        the converted `x`.
    Examples
    -----
    >>> from numpy.polynomial.hermite_e import hermevander
    >>> x = np.array([-1, 0, 1])
    >>> hermevander(x, 3)
    array([[ 1., -1.,  0.,  2.],
           [ 1.,  0., -1., -0.],

1006: (4)             Return the coefficients of a HermiteE series of degree `deg` that is
1007: (4)             the least squares fit to the data values `y` given at points `x`. If
1008: (4)             `y` is 1-D the returned coefficients will also be 1-D. If `y` is 2-D
1009: (4)             multiple fits are done, one for each column of `y`, and the resulting
1010: (4)             coefficients are stored in the corresponding columns of a 2-D return.
1011: (4)             The fitted polynomial(s) are in the form
1012: (4)             .. math:: p(x) = c_0 + c_1 * He_1(x) + ... + c_n * He_n(x),
1013: (4)             where `n` is `deg`.
1014: (4)             Parameters
1015: (4)
1016: (4)             x : array_like, shape (M,)
1017: (8)             x-coordinates of the M sample points ``(x[i], y[i])``.
1018: (4)             y : array_like, shape (M,) or (M, K)
1019: (8)             y-coordinates of the sample points. Several data sets of sample
1020: (8)             points sharing the same x-coordinates can be fitted at once by
1021: (8)             passing in a 2D-array that contains one dataset per column.
1022: (4)             deg : int or 1-D array_like
1023: (8)             Degree(s) of the fitting polynomials. If `deg` is a single integer
1024: (8)             all terms up to and including the `deg`'th term are included in the
1025: (8)             fit. For NumPy versions >= 1.11.0 a list of integers specifying the
1026: (8)             degrees of the terms to include may be used instead.
1027: (4)             rcond : float, optional
1028: (8)             Relative condition number of the fit. Singular values smaller than
1029: (8)             this relative to the largest singular value will be ignored. The
1030: (8)             default value is len(x)*eps, where eps is the relative precision of
1031: (8)             the float type, about 2e-16 in most cases.
1032: (4)             full : bool, optional
1033: (8)             Switch determining nature of return value. When it is False (the
1034: (8)             default) just the coefficients are returned, when True diagnostic
1035: (8)             information from the singular value decomposition is also returned.
1036: (4)             w : array_like, shape (M,), optional
1037: (8)             Weights. If not None, the weight ``w[i]`` applies to the unsquared
1038: (8)             residual ``y[i] - y_hat[i]`` at ``x[i]``. Ideally the weights are
1039: (8)             chosen so that the errors of the products ``w[i]*y[i]`` all have the
1040: (8)             same variance. When using inverse-variance weighting, use
1041: (8)             ``w[i] = 1/sigma(y[i])``. The default value is None.
1042: (4)             Returns
1043: (4)
1044: (4)             coef : ndarray, shape (M,) or (M, K)
1045: (8)             Hermite coefficients ordered from low to high. If `y` was 2-D,
1046: (8)             the coefficients for the data in column k of `y` are in column
1047: (8)             `k`.
1048: (4)             [residuals, rank, singular_values, rcond] : list
1049: (8)             These values are only returned if ``full == True``
1050: (8)             - residuals -- sum of squared residuals of the least squares fit
1051: (8)             - rank -- the numerical rank of the scaled Vandermonde matrix
1052: (8)             - singular_values -- singular values of the scaled Vandermonde matrix

1072: (4)          hermeval : Evaluates a Hermite series.
1073: (4)          hermevander : pseudo Vandermonde matrix of Hermite series.
1074: (4)          hermeweight : HermiteE weight function.
1075: (4)          numpy.linalg.lstsq : Computes a least-squares fit from the matrix.
1076: (4)          scipy.interpolate.UnivariateSpline : Computes spline fits.
1077: (4)          Notes
1078: (4)          -----
1079: (4)          The solution is the coefficients of the HermiteE series `p` that
1080: (4)          minimizes the sum of the weighted squared errors
1081: (4)          .. math:: E = \sum_j w_j^2 * |y_j - p(x_j)|^2,
1082: (4)          where the :math:`w_j` are the weights. This problem is solved by
1083: (4)          setting up the (typically) overdetermined matrix equation
1084: (4)          .. math:: V(x) * c = w * y,
1085: (4)          where `V` is the pseudo Vandermonde matrix of `x`, the elements of `c`
1086: (4)          are the coefficients to be solved for, and the elements of `y` are the
1087: (4)          observed values. This equation is then solved using the singular value
1088: (4)          decomposition of `V`.
1089: (4)          If some of the singular values of `V` are so small that they are
1090: (4)          neglected, then a `RankWarning` will be issued. This means that the
1091: (4)          coefficient values may be poorly determined. Using a lower order fit
1092: (4)          will usually get rid of the warning. The `rcond` parameter can also be
1093: (4)          set to a value smaller than its default, but the resulting fit may be
1094: (4)          spurious and have large contributions from roundoff error.
1095: (4)          Fits using HermiteE series are probably most useful when the data can
1096: (4)          be approximated by ``sqrt(w(x)) * p(x)``, where `w(x)` is the HermiteE
1097: (4)          weight. In that case the weight ``sqrt(w(x[i]))`` should be used
1098: (4)          together with data values ``y[i]/sqrt(w(x[i]))``. The weight function is
1099: (4)          available as `hermeweight`.

574: (4)          See Also
575: (4)          -----
576: (4)          lagder
577: (4)          Notes
578: (4)          -----
579: (4)          Note that the result of each integration is *multiplied* by `scl`.
580: (4)          Why is this important to note? Say one is making a linear change of
581: (4)          variable :math:`u = ax + b` in an integral relative to `x`. Then
582: (4)          :math:`dx = du/a`, so one will need to set `scl` equal to
583: (4)          :math:`1/a` - perhaps not what one would have first thought.
584: (4)          Also note that, in general, the result of integrating a C-series needs
585: (4)          to be "reprojected" onto the C-series basis set. Thus, typically,
586: (4)          the result of this function is "unintuitive," albeit correct; see
587: (4)          Examples section below.
588: (4)          Examples
589: (4)          -----

638: (0)             def lagval(x, c, tensor=True):
639: (4)                 """
640: (4)                 Evaluate a Laguerre series at points x.
641: (4)                 If `c` is of length `n + 1`, this function returns the value:
642: (4)                 .. math:: p(x) = c_0 * L_0(x) + c_1 * L_1(x) + \dots + c_n * L_n(x)
643: (4)                 The parameter `x` is converted to an array only if it is a tuple or a
644: (4)                 list, otherwise it is treated as a scalar. In either case, either `x`
645: (4)                 or its elements must support multiplication and addition both with
646: (4)                 themselves and with the elements of `c`.
647: (4)                 If `c` is a 1-D array, then `p(x)` will have the same shape as `x`. If
648: (4)                 `c` is multidimensional, then the shape of the result depends on the
649: (4)                 value of `tensor`. If `tensor` is true the shape will be `c.shape[1:] + x.shape`. If `tensor` is false the shape will be `c.shape[1:]`. Note that
650: (4)                 scalars have shape ().
651: (4)                 Trailing zeros in the coefficients will be used in the evaluation, so
652: (4)                 they should be avoided if efficiency is a concern.
653: (4)             Parameters
654: (4)             -----
655: (4)             x : array_like, compatible object
656: (4)                 If `x` is a list or tuple, it is converted to an ndarray, otherwise
657: (8)                 it is left unchanged and treated as a scalar. In either case, `x`
658: (8)                 or its elements must support addition and multiplication with
659: (8)                 themselves and with the elements of `c`.
660: (8)             c : array_like
661: (4)                 Array of coefficients ordered so that the coefficients for terms of
662: (8)                 degree n are contained in c[n]. If `c` is multidimensional the
663: (8)                 remaining indices enumerate multiple polynomials. In the two
664: (8)                 dimensional case the coefficients may be thought of as stored in
665: (8)                 the columns of `c`.
666: (8)             tensor : boolean, optional
667: (4)                 If True, the shape of the coefficient array is extended with ones
668: (8)                 on the right, one for each dimension of `x`. Scalars have dimension 0
669: (8)                 for this action. The result is that every column of coefficients in
670: (8)                 `c` is evaluated for every element of `x`. If False, `x` is broadcast
671: (8)                 over the columns of `c` for the evaluation. This keyword is useful
672: (8)                 when `c` is multidimensional. The default value is True.

1010: (4)          least squares fit to the data values `y` given at points `x`. If `y` is
1011: (4)          1-D the returned coefficients will also be 1-D. If `y` is 2-D multiple
1012: (4)          fits are done, one for each column of `y`, and the resulting
1013: (4)          coefficients are stored in the corresponding columns of a 2-D return.
1014: (4)          The fitted polynomial(s) are in the form
1015: (4)          .. math:: p(x) = c_0 + c_1 * L_1(x) + \dots + c_n * L_n(x),
1016: (4)          where ``n`` is `deg`.
1017: (4)          Parameters
1018: (4)          -----
1019: (8)          x : array_like, shape (M,)
1020: (4)          x-coordinates of the M sample points ``x[i], y[i]``.
1021: (8)          y : array_like, shape (M,) or (M, K)
1022: (8)          y-coordinates of the sample points. Several data sets of sample
1023: (8)          points sharing the same x-coordinates can be fitted at once by
1024: (4)          passing in a 2D-array that contains one dataset per column.
1025: (8)          deg : int or 1-D array_like
1026: (8)          Degree(s) of the fitting polynomials. If `deg` is a single integer
1027: (8)          all terms up to and including the `deg`'th term are included in the
               fit. For NumPy versions >= 1.11.0 a list of integers specifying the

```

```

1028: (8)           degrees of the terms to include may be used instead.
1029: (4)           rcond : float, optional
1030: (8)             Relative condition number of the fit. Singular values smaller than
1031: (8)             this relative to the largest singular value will be ignored. The
1032: (8)             default value is len(x)*eps, where eps is the relative precision of
1033: (8)             the float type, about 2e-16 in most cases.
1034: (4)           full : bool, optional
1035: (8)             Switch determining nature of return value. When it is False (the
1036: (8)             default) just the coefficients are returned, when True diagnostic
1037: (8)             information from the singular value decomposition is also returned.
1038: (4)           w : array_like, shape (`M`,), optional
1039: (8)             Weights. If not None, the weight ``w[i]`` applies to the unsquared
1040: (8)             residual ``y[i] - y_hat[i]`` at ``x[i]``. Ideally the weights are
1041: (8)             chosen so that the errors of the products ``w[i]*y[i]`` all have the
1042: (8)             same variance. When using inverse-variance weighting, use
1043: (8)             ``w[i] = 1/sigma(y[i])``. The default value is None.
1044: (4)           Returns
1045: (4)           -----
1046: (4)           coef : ndarray, shape (M,) or (M, K)
1047: (8)             Laguerre coefficients ordered from low to high. If `y` was 2-D,
1048: (8)             the coefficients for the data in column *k* of `y` are in column
1049: (8)             *k*.
1050: (4)           [residuals, rank, singular_values, rcond] : list
1051: (8)             These values are only returned if ``full == True``
1052: (8)             - residuals -- sum of squared residuals of the least squares fit
1053: (8)             - rank -- the numerical rank of the scaled Vandermonde matrix
1054: (8)             - singular_values -- singular values of the scaled Vandermonde matrix
1055: (8)             - rcond -- value of `rcond`.
1056: (8)             For more details, see `numpy.linalg.lstsq`.
1057: (4)           Warns
1058: (4)           -----
1059: (4)           RankWarning
1060: (8)             The rank of the coefficient matrix in the least-squares fit is
1061: (8)             deficient. The warning is only raised if ``full == False``. The
1062: (8)             warnings can be turned off by
1063: (8)               >>> import warnings
1064: (8)               >>> warnings.simplefilter('ignore', np.RankWarning)
1065: (4)           See Also

1073: (4)           lagvander : pseudo Vandermonde matrix of Laguerre series.
1074: (4)           lagweight : Laguerre weight function.
1075: (4)           numpy.linalg.lstsq : Computes a least-squares fit from the matrix.
1076: (4)           scipy.interpolate.UnivariateSpline : Computes spline fits.
1077: (4)           Notes
1078: (4)           -----
1079: (4)           The solution is the coefficients of the Laguerre series ``p`` that
1080: (4)           minimizes the sum of the weighted squared errors
1081: (4)           .. math:: E = \sum_j w_j^2 * |y_j - p(x_j)|^2,
1082: (4)           where the :math:`w_j` are the weights. This problem is solved by
1083: (4)           setting up as the (typically) overdetermined matrix equation
1084: (4)           .. math:: V(x) * c = w * y,
1085: (4)           where ``V`` is the weighted pseudo Vandermonde matrix of `x`, ``c`` are
the
1086: (4)           coefficients to be solved for, `w` are the weights, and `y` are the
1087: (4)           observed values. This equation is then solved using the singular value
1088: (4)           decomposition of ``V``.
1089: (4)           If some of the singular values of `V` are so small that they are
1090: (4)           neglected, then a `RankWarning` will be issued. This means that the
1091: (4)           coefficient values may be poorly determined. Using a lower order fit
1092: (4)           will usually get rid of the warning. The `rcond` parameter can also be
1093: (4)           set to a value smaller than its default, but the resulting fit may be
1094: (4)           spurious and have large contributions from roundoff error.
1095: (4)           Fits using Laguerre series are probably most useful when the data can

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1096: (4)      be approximated by ``sqrt(w(x)) * p(x)`` , where ``w(x)`` is the Laguerre
1097: (4)      weight. In that case the weight ``sqrt(w(x[i]))`` should be used
1098: (4)      together with data values ``y[i]/sqrt(w(x[i]))`` . The weight function is
1099: (4)      available as `lagweight`.

1197: (4) return r
1198: (0) def laggauss(deg):
1199: (4) """
1200: (4) Gauss-Laguerre quadrature.
1201: (4) Computes the sample points and weights for Gauss-Laguerre quadrature.
1202: (4) These sample points and weights will correctly integrate polynomials of
1203: (4) degree :math:`2*deg - 1` or less over the interval :math:`[0, \infty]`
1204: (4) with the weight function :math:`f(x) = \exp(-x)`.

Parameters
-----
deg : int
    Number of sample points and weights. It must be >= 1.

Returns
-----
x : ndarray
    1-D ndarray containing the sample points.
y : ndarray
    1-D ndarray containing the weights.

Notes
-----
.. versionadded:: 1.7.0
The results have only been tested up to degree 100 higher degrees may
be problematic. The weights are determined by using the fact that
.. math:: w_k = c / (L'_n(x_k) * L_{n-1}(x_k))
where :math:`c` is a constant independent of :math:`k` and :math:`x_k` is the k'th root of :math:`L_n`, and then scaling the results to get
the right value when integrating 1.

=====
Legendre Series (:mod:`numpy.polynomial.legendre`)
=====

This module provides a number of objects (mostly functions) useful for dealing with Legendre series, including a `Legendre` class that encapsulates the usual arithmetic operations. (General information on how this module represents and works with such polynomials is in the docstring for its "parent" sub-package, `numpy.polynomial`).

589: (4)             Returns
590: (4)                 -----
591: (4)                 S : ndarray
592: (8)                     Legendre series coefficient array of the integral.
593: (4)             Raises
594: (4)                 -----
595: (4)                 ValueError
596: (8)                     If ``m < 0``, ``len(k) > m``, ``np.ndim(lbnd) != 0``, or
597: (8)                     ``np.ndim(scl) != 0``.
598: (4)             See Also
599: (4)                 -----
600: (4)                 legder
601: (4)                 Notes
602: (4)                 -----
603: (4)                 Note that the result of each integration is *multiplied* by `scl`.
604: (4)                 Why is this important to note? Say one is making a linear change of
605: (4)                 variable :math:`u = ax + b` in an integral relative to `x`. Then
606: (4)                 :math:`dx = du/a`, so one will need to set `scl` equal to
607: (4)                 :math:`1/a` - perhaps not what one would have first thought.
608: (4)                 Also note that, in general, the result of integrating a C-series needs
609: (4)                 to be "reprojected" onto the C-series basis set. Thus, typically,
610: (4)                 the result of this function is "unintuitive," albeit correct; see
611: (4)                 Examples section below.
612: (4)             Examples
613: (4)                 -----

1020: (4)               Least squares fit of Legendre series to data.
1021: (4)               Return the coefficients of a Legendre series of degree `deg` that is the
1022: (4)               least squares fit to the data values `y` given at points `x` . If `y` is
1023: (4)               1-D the returned coefficients will also be 1-D. If `y` is 2-D multiple
1024: (4)               fits are done, one for each column of `y` , and the resulting
1025: (4)               coefficients are stored in the corresponding columns of a 2-D return.
1026: (4)               The fitted polynomial(s) are in the form
1027: (4)               .. math:: p(x) = c_0 + c_1 * L_1(x) + \dots + c_n * L_n(x),
1028: (4)               where `n` is `deg` .
1029: (4)           Parameters
1030: (4)             -----
1031: (8)             x : array_like, shape (M,)
1032: (4)               x-coordinates of the M sample points ``x[i], y[i]`` .
1031: (8)             y : array_like, shape (M,) or (M, K)

```

```

1033: (8) y-coordinates of the sample points. Several data sets of sample
1034: (8) points sharing the same x-coordinates can be fitted at once by
1035: (8) passing in a 2D-array that contains one dataset per column.
1036: (4) deg : int or 1-D array_like
1037: (8) Degree(s) of the fitting polynomials. If `deg` is a single integer
1038: (8) all terms up to and including the `deg`'th term are included in the
1039: (8) fit. For NumPy versions >= 1.11.0 a list of integers specifying the
1040: (8) degrees of the terms to include may be used instead.
1041: (4) rcond : float, optional
1042: (8) Relative condition number of the fit. Singular values smaller than
1043: (8) this relative to the largest singular value will be ignored. The
1044: (8) default value is  $\text{len}(x)*\text{eps}$ , where  $\text{eps}$  is the relative precision of
1045: (8) the float type, about  $2e-16$  in most cases.
1046: (4) full : bool, optional
1047: (8) Switch determining nature of return value. When it is False (the
1048: (8) default) just the coefficients are returned, when True diagnostic
1049: (8) information from the singular value decomposition is also returned.
1050: (4) w : array_like, shape (M,), optional
1051: (8) Weights. If not None, the weight ``w[i]`` applies to the unsquared
1052: (8) residual ``y[i] - y_hat[i]`` at ``x[i]``. Ideally the weights are
1053: (8) chosen so that the errors of the products ``w[i]*y[i]`` all have the
1054: (8) same variance. When using inverse-variance weighting, use
1055: (8) ``w[i] = 1/sigma(y[i])``. The default value is None.
1056: (8) .. versionadded:: 1.5.0
1057: (4) Returns
1058: (4) -----
1059: (4) coef : ndarray, shape (M,) or (M, K)
1060: (8) Legendre coefficients ordered from low to high. If `y` was
1061: (8) 2-D, the coefficients for the data in column k of `y` are in
1062: (8) column `k`. If `deg` is specified as a list, coefficients for
1063: (8) terms not included in the fit are set equal to zero in the
1064: (8) returned `coef`.
1065: (4) [residuals, rank, singular_values, rcond] : list
1066: (8) These values are only returned if ``full == True``
1067: (8) - residuals -- sum of squared residuals of the least squares fit
1068: (8) - rank -- the numerical rank of the scaled Vandermonde matrix
1069: (8) - singular_values -- singular values of the scaled Vandermonde matrix
1070: (8) - rcond -- value of `rcond`.
1071: (8) For more details, see `numpy.linalg.lstsq`.
1072: (4) Warns
1073: (4) -----
1074: (4) RankWarning
1075: (8) The rank of the coefficient matrix in the least-squares fit is
1076: (8) deficient. The warning is only raised if ``full == False``. The
1077: (8) warnings can be turned off by
1078: (8) >>> import warnings
1079: (8) >>> warnings.simplefilter('ignore', np.RankWarning)
1080: (4) See Also
1081: (4) -----

1083: (4) numpy.polynomial.chebyshev.chebfit
1084: (4) numpy.polynomial.laguerre.lagfit
1085: (4) numpy.polynomial.hermite.hermfit
1086: (4) numpy.polynomial.hermite_e.hermefit
1087: (4) legval : Evaluates a Legendre series.
1088: (4) legvander : Vandermonde matrix of Legendre series.
1089: (4) legweight : Legendre weight function (= 1).
1090: (4) numpy.linalg.lstsq : Computes a least-squares fit from the matrix.
1091: (4) scipy.interpolate.UnivariateSpline : Computes spline fits.
1092: (4) Notes
1093: (4) -----
1094: (4) The solution is the coefficients of the Legendre series `p` that
1095: (4) minimizes the sum of the weighted squared errors
1096: (4) .. math:: E = \sum_j w_j^2 * |y_j - p(x_j)|^2,
1097: (4) where :math:`w_j` are the weights. This problem is solved by setting up
1098: (4) as the (typically) overdetermined matrix equation
1099: (4) .. math:: V(x) * c = w * y,
1100: (4) where `V` is the weighted pseudo Vandermonde matrix of `x`, `c` are the
1101: (4) coefficients to be solved for, `w` are the weights, and `y` are the

```

```

1102: (4) observed values. This equation is then solved using the singular value
1103: (4) decomposition of `V`.
1104: (4) If some of the singular values of `V` are so small that they are
1105: (4) neglected, then a `RankWarning` will be issued. This means that the
1106: (4) coefficient values may be poorly determined. Using a lower order fit
1107: (4) will usually get rid of the warning. The `rcond` parameter can also be
1108: (4) set to a value smaller than its default, but the resulting fit may be
1109: (4) spurious and have large contributions from roundoff error.
1110: (4) Fits using Legendre series are usually better conditioned than fits
1111: (4) using power series, but much can depend on the distribution of the
1112: (4) sample points and the smoothness of the data. If the quality of the fit
1113: (4) is inadequate splines may be a good alternative.

Power Series (:mod:`numpy.polynomial.polynomial`)

This module provides a number of objects (mostly functions) useful for dealing with polynomials, including a `Polynomial` class that encapsulates the usual arithmetic operations. (General information on how this module represents and works with polynomial objects is in the docstring for its "parent" sub-package, `numpy.polynomial`).

105: (4) if scl != 0:
106: (8)     return np.array([off, scl])
107: (4) else:
108: (8)     return np.array([off])
109: (0) def polyfromroots(roots):
110: (4) """
111: (4) Generate a monic polynomial with given roots.
112: (4) Return the coefficients of the polynomial
113: (4) .. math:: p(x) = (x - r_0) * (x - r_1) * ... * (x - r_n),
114: (4) where the ``r_n`` are the roots specified in `roots`. If a zero has
115: (4) multiplicity n, then it must appear in `roots` n times. For instance,
116: (4) if 2 is a root of multiplicity three and 3 is a root of multiplicity 2,
117: (4) then `roots` looks something like [2, 2, 2, 3, 3]. The roots can appear
118: (4) in any order.
119: (4) If the returned coefficients are `c`, then
120: (4) .. math:: p(x) = c_0 + c_1 * x + ... + x^n
121: (4) The coefficient of the last term is 1 for monic polynomials in this
122: (4) form.
123: (4) Parameters
124: (4) -----
125: (4) roots : array_like
126: (8)     Sequence containing the roots.
127: (4) Returns
128: (4) -----
129: (4) out : ndarray
130: (8)     1-D array of the polynomial's coefficients If all the roots are
131: (8)     real, then `out` is also real, otherwise it is complex. (see
132: (8)     Examples below).
133: (4) See Also

    `axis`. At each iteration the result is multiplied by `scl` (the
    scaling factor is for use in a linear change of variable). The
    argument `c` is an array of coefficients from low to high degree along
    each axis, e.g., [1,2,3] represents the polynomial ``1 + 2*x + 3*x**2``
    while [[1,2],[1,2]] represents ``1 + 1*x + 2*y + 2*x*y`` if axis=0 is
    ``x`` and axis=1 is ``y``.
    Parameters
    -----
    c : array_like
        Array of polynomial coefficients. If c is multidimensional the
        different axis correspond to different variables with the degree
        in each axis given by the corresponding index.
    m : int, optional
        Number of derivatives taken, must be non-negative. (Default: 1)
    scl : scalar, optional
        Each differentiation is multiplied by `scl`. The end result is
        multiplication by ``scl**m``. This is for use in a linear change
        of variable. (Default: 1)
    axis : int, optional
        Axis over which the derivative is taken. (Default: 0).
        .. versionadded:: 1.7.0
    Returns
    -----
    der : ndarray
        Polynomial coefficients of the derivative.
    See Also
    -----
    polyint
    Examples
    -----
    >>> from numpy.polynomial import polynomial as P
    >>> c = (1,2,3,4) # 1 + 2x + 3x**2 + 4x**3
    >>> P.polyder(c) # (d/dx)(c) = 2 + 6x + 12x**2

def polyfit(x, y, deg, rcond=None, full=False, w=None):
    """
    Least-squares fit of a polynomial to data.
    Return the coefficients of a polynomial of degree `deg` that is the
    least squares fit to the data values `y` given at points `x`. If `y` is
    1-D the returned coefficients will also be 1-D. If `y` is 2-D multiple
    fits are done, one for each column of `y`, and the resulting
    coefficients are stored in the corresponding columns of a 2-D return.
    The fitted polynomial(s) are in the form
    .. math:: p(x) = c_0 + c_1 * x + \dots + c_n * x^n,
    where `n` is `deg`.
    Parameters
    -----
    x : array_like, shape (`M`,)
        x-coordinates of the `M` sample (data) points ``x[i], y[i]``.
    y : array_like, shape (`M`,) or (`M`, `K`)
        y-coordinates of the sample points. Several sets of sample points
        sharing the same x-coordinates can be (independently) fit with one
        call to `polyfit` by passing in for `y` a 2-D array that contains
        one data set per column.
    deg : int or 1-D array_like
        Degree(s) of the fitting polynomials. If `deg` is a single integer
        all terms up to and including the `deg`'th term are included in the
        fit. For NumPy versions >= 1.11.0 a list of integers specifying the
        degrees of the terms to include may be used instead.
    rcond : float, optional
        Relative condition number of the fit. Singular values smaller
        than `rcond`, relative to the largest singular value, will be
        ignored. The default value is ``len(x)*eps``, where `eps` is the
        relative precision of the platform's float type, about 2e-16 in
        most cases.
    full : bool, optional
        Switch determining the nature of the return value. When ``False``
        (the default) just the coefficients are returned; when ``True``,
        diagnostic information from the singular value decomposition (used
        to solve the fit's matrix equation) is also returned.
    w : array_like, shape (`M`,), optional
        Weights. If not None, the weight ``w[i]`` applies to the unsquared
        residual ``y[i] - y_hat[i]`` at ``x[i]``. Ideally the weights are
        chosen so that the errors of the products ``w[i]*y[i]`` all have the
        same variance. When using inverse-variance weighting, use
        ``w[i] = 1/sigma(y[i])``. The default value is None.
        .. versionadded:: 1.5.0
    Returns
    -----
    coef : ndarray, shape (`deg` + 1,) or (`deg` + 1, `K`)
        Polynomial coefficients ordered from low to high. If `y` was 2-D,
        the coefficients in column `k` of `coef` represent the polynomial
        fit to the data in `y`'s `k`-th column.
    [residuals, rank, singular_values, rcond] : list
        These values are only returned if ``full == True``
        - residuals -- sum of squared residuals of the least squares fit
        - rank -- the numerical rank of the scaled Vandermonde matrix
        - singular_values -- singular values of the scaled Vandermonde matrix
        - rcond -- value of `rcond`.
        For more details, see `numpy.linalg.lstsq`.
    Raises
    -----
    RankWarning
        Raised if the matrix in the least-squares fit is rank deficient.
        The warning is only raised if ``full == False``. The warnings can
        be turned off by:
        >>> import warnings
        >>> warnings.simplefilter('ignore', np.RankWarning)

1026: (4) numpy.polynomial.hermite.hermfit
1027: (4) numpy.polynomial.hermite_e.hermefit
1028: (4) polyval : Evaluates a polynomial.
1029: (4) polyvander : Vandermonde matrix for powers.
1030: (4) numpy.linalg.lstsq : Computes a least-squares fit from the matrix.
1031: (4) scipy.interpolate.UnivariateSpline : Computes spline fits.
1032: (4) Notes
1033: (4)
1034: (4) -----
1035: (4) The solution is the coefficients of the polynomial `p` that minimizes
1036: (4) the sum of the weighted squared errors
1037: (4) .. math:: E = \sum_j w_j^2 * |y_j - p(x_j)|^2,
1038: (4) where the :math:`w_j` are the weights. This problem is solved by
1039: (4) setting up the (typically) over-determined matrix equation:
1040: (4) .. math:: V(x) * c = w * y,
1041: (4) where `V` is the weighted pseudo Vandermonde matrix of `x`, `c` are the
1042: (4) coefficients to be solved for, `w` are the weights, and `y` are the
1043: (4) observed values. This equation is then solved using the singular value
1044: (4) decomposition of `V`.
1045: (4) If some of the singular values of `V` are so small that they are
1046: (4) neglected (and `full` == ``False``), a `RankWarning` will be raised.
1047: (4) This means that the coefficient values may be poorly determined.
1048: (4) Fitting to a lower order polynomial will usually get rid of the warning
1049: (4) (but may not be what you want, of course; if you have independent
1050: (4) reason(s) for choosing the degree which isn't working, you may have to:
1051: (4) a) reconsider those reasons, and/or b) reconsider the quality of your
1052: (4) data). The `rcond` parameter can also be set to a value smaller than
1053: (4) its default, but the resulting fit may be spurious and have large
1054: (4) contributions from roundoff error.
1055: (4) Polynomial fits using double precision tend to "fail" at about
1056: (4) (polynomial) degree 20. Fits using Chebyshev or Legendre series are
1057: (4) generally better conditioned, but much can still depend on the
1058: (4) distribution of the sample points and the smoothness of the data. If
1059: (4) the quality of the fit is inadequate, splines may be a good
1060: (4) alternative.
1061: (4) Examples
1062: (4)
1063: (4) -----
1064: (4) >>> np.random.seed(123)
1065: (4) >>> from numpy.polynomial import polynomial as P
1066: (4) >>> x = np.linspace(-1,1,51) # x "data": [-1, -0.96, ..., 0.96, 1]
1067: (4) >>> y = x**3 - x + np.random.randn(len(x)) # x^3 - x + Gaussian noise
1068: (4) >>> c, stats = P.polyfit(x,y,3,full=True)
1069: (4) >>> c # c[0], c[2] should be approx. 0, c[1] approx. -1, c[3] approx. 1
1070: (4) array([ 0.01909725, -1.30598256, -0.00577963,  1.02644286]) # may vary
1071: (5) >>> stats # note the large SSR, explaining the rather poor results
# may vary
1072: (14) [array([ 38.06116253]), 4, array([ 1.38446749,  1.32119158,  0.50443316,
1073: (4) 0.28853036]), 1.1324274851176597e-014]
1074: (4) Same thing without the added noise
1075: (4) >>> y = x**3 - x
1076: (4) >>> c, stats = P.polyfit(x,y,3,full=True)
1077: (4) >>> c # c[0], c[2] should be "very close to 0", c[1] ~= -1, c[3] ~= 1
1.00000000e+00]

    """The degree of the series.
.. versionadded:: 1.5.0
Returns
-----
degree : int
    Degree of the series, one less than the number of coefficients.
Examples
-----
Create a polynomial object for ``1 + 7*x + 4*x**2`` :
>>> poly = np.polynomial.Polynomial([1, 7, 4])
>>> print(poly)
1.0 + 7.0*x + 4.0*x^2
>>> poly.degree()
2
Note that this method does not check for non-zero coefficients.
You must trim the polynomial to remove any trailing zeroes:
>>> poly = np.polynomial.Polynomial([1, 7, 0])
>>> print(poly)
1.0 + 7.0*x + 0.0*x^2
>>> poly.degree()
2
>>> poly.trim().degree()
1
"""

Reduce the degree of the series to `deg` by discarding the
high order terms. If `deg` is greater than the current degree a
copy of the current series is returned. This can be useful in least
squares where the coefficients of the high degree terms may be very
small.
.. versionadded:: 1.5.0
Parameters
-----
deg : non-negative int
    The series is reduced to degree `deg` by discarding the high
    order terms. The value of `deg` must be a non-negative integer.
Returns
-----
new_series : series
    New instance of series with reduced degree.
"""

749: (8)             Return a series instance that is the least squares fit to the data
750: (8)             `y` sampled at `x`. The domain of the returned instance can be
751: (8)             specified and this will often result in a superior fit with less
752: (8)             chance of ill conditioning.
753: (8)             Parameters
754: (12)             -----
755: (8)             x : array_like, shape (M,)
756: (12)               x-coordinates of the M sample points ``(x[i], y[i])``.
757: (8)             y : array_like, shape (M,)
758: (12)               y-coordinates of the M sample points ``(x[i], y[i])``.
759: (12)             deg : int or 1-D array_like
760: (12)               Degree(s) of the fitting polynomials. If `deg` is a single integer
761: (8)                 all terms up to and including the `deg`'th term are included in
762: (8)                 the
763: (12)                 fit. For NumPy versions >= 1.11.0 a list of integers specifying
764: (8)                 degrees of the terms to include may be used instead.
765: (12)             domain : {None, [beg, end], []}, optional
766: (12)               Domain to use for the returned series. If ``None``,
767: (12)               then a minimal domain that covers the points `x` is chosen. If
768: (12)               ``[]`` the class domain is used. The default value was the
769: (12)               class domain in NumPy 1.4 and ``None`` in later versions.
770: (12)               The ``[]`` option was added in numpy 1.5.0.
771: (12)             rcond : float, optional
772: (12)               Relative condition number of the fit. Singular values smaller
773: (12)               than this relative to the largest singular value will be
774: (8)                 ignored. The default value is len(x)*eps, where eps is the
775: (12)                 relative precision of the float type, about 2e-16 in most
776: (12)                 cases.
777: (12)             full : bool, optional
778: (12)               Switch determining nature of return value. When it is False
779: (8)                 (the default) just the coefficients are returned, when True
780: (12)                 diagnostic information from the singular value decomposition is
781: (12)                 also returned.
782: (12)             w : array_like, shape (M,), optional
783: (12)               Weights. If not None, the weight ``w[i]`` applies to the unsquared
784: (12)               residual ``y[i] - y_hat[i]`` at ``x[i]``. Ideally the weights are
785: (12)               chosen so that the errors of the products ``w[i]*y[i]`` all have
786: (8)                 the same variance. When using inverse-variance weighting, use
787: (12)                 ``w[i] = 1/sigma(y[i])``. The default value is None.
788: (12)               .. versionadded:: 1.5.0
789: (12)             window : {[beg, end]}, optional
789: (12)               Window to use for the returned series. The default
789: (12)               value is the default class domain

#### File 296 - \_\_init\_\_.py:

```

1: (0)             """
2: (0)             A sub-package for efficiently dealing with polynomials.
3: (0)             Within the documentation for this sub-package, a "finite power series,"
4: (0)             i.e., a polynomial (also referred to simply as a "series") is represented
5: (0)             by a 1-D numpy array of the polynomial's coefficients, ordered from lowest
6: (0)             order term to highest. For example, array([1,2,3]) represents
7: (0)             ``P_0 + 2*P_1 + 3*P_2``, where P_n is the n-th order basis polynomial
8: (0)             applicable to the specific module in question, e.g., `polynomial` (which
9: (0)             "wraps" the "standard" basis) or `chebyshev`. For optimal performance,
10: (0)             all operations on polynomials, including evaluation at an argument, are
11: (0)             implemented as operations on the coefficients. Additional (module-specific)
12: (0)             information can be found in the docstring for the module of interest.
13: (0)             This package provides *convenience classes* for each of six different kinds
14: (0)             of polynomials:
15: (9)             =====      =====
16: (9)             **Name**      **Provides**
17: (9)             =====      =====
18: (9)             `~polynomial.Polynomial`      Power series
19: (9)             `~chebyshev.Chebyshev`      Chebyshev series
20: (9)             `~legendre.Legendre`      Legendre series
21: (9)             `~laguerre.Laguerre`      Laguerre series
22: (9)             `~hermite.Hermite`      Hermite series
23: (9)             `~hermite_e.HermiteE`      HermiteE series
24: (9)             =====      =====
25: (0)             These *convenience classes* provide a consistent interface for creating,
26: (0)             manipulating, and fitting data with polynomials of different bases.
27: (0)             The convenience classes are the preferred interface for the
`~numpy.polynomial`  

28: (0)             package, and are available from the ``numpy.polynomial`` namespace.
29: (0)             This eliminates the need to navigate to the corresponding submodules, e.g.
30: (0)             ``np.polynomial.Polynomial`` or ``np.polynomial.Chebyshev`` instead of
31: (0)             ``np.polynomial.polynomial.Polynomial`` or
32: (0)             ``np.polynomial.chebyshev.Chebyshev``, respectively.
33: (0)             The classes provide a more consistent and concise interface than the
```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

34: (0) type-specific functions defined in the submodules for each type of polynomial.
35: (0) For example, to fit a Chebyshev polynomial with degree ``1`` to data given
36: (0) by arrays ``xdata`` and ``ydata``, the
37: (0) `~chebyshev.Chebyshev.fit` class method::
38: (4)     >>> from numpy.polynomial import Chebyshev
39: (4)     >>> c = Chebyshev.fit(xdata, ydata, deg=1)
40: (0) is preferred over the `chebyshev.chebfit` function from the
41: (0) ``np.polynomial.chebyshev`` module::
42: (4)     >>> from numpy.polynomial.chebyshev import chebfit
43: (4)     >>> c = chebfit(xdata, ydata, deg=1)
44: (0) See :doc:`routines.polynomials.classes` for more details.
45: (0) Convenience Classes
46: (0) =====
47: (0) The following lists the various constants and methods common to all of
48: (0) the classes representing the various kinds of polynomials. In the following,
49: (0) the term ``Poly`` represents any one of the convenience classes (e.g.
50: (0) `~polynomial.Polynomial`, `~chebyshev.Chebyshev`, `~hermite.Hermite`, etc.)
51: (0) while the lowercase ``p`` represents an **instance** of a polynomial class.
52: (0) Constants
53: (0) -----
54: (0) - ``Poly.domain`` -- Default domain
55: (0) - ``Poly.window`` -- Default window
56: (0) - ``Poly.basis_name`` -- String used to represent the basis
57: (0) - ``Poly.maxpower`` -- Maximum value ``n`` such that ``p**n`` is allowed
58: (0) - ``Poly.nickname`` -- String used in printing
59: (0) Creation
60: (0) -----
61: (0) Methods for creating polynomial instances.
62: (0) - ``Poly.basis(degree)`` -- Basis polynomial of given degree
63: (0) - ``Poly.identity()`` -- ``p`` where ``p(x) = x`` for all ``x``
64: (0) - ``Poly.fit(x, y, deg)`` -- ``p`` of degree ``deg`` with coefficients
65: (2) determined by the least-squares fit to the data ``x``, ``y``
66: (0) - ``Poly.fromroots(roots)`` -- ``p`` with specified roots
67: (0) - ``p.copy()`` -- Create a copy of ``p``
68: (0) Conversion
69: (0) -----
70: (0) Methods for converting a polynomial instance of one kind to another.
71: (0) - ``p.cast(Poly)`` -- Convert ``p`` to instance of kind ``Poly``
72: (0) - ``p.convert(Poly)`` -- Convert ``p`` to instance of kind ``Poly`` or map
73: (2) between ``domain`` and ``window``
74: (0) Calculus
75: (0) -----
76: (0) - ``p.deriv()`` -- Take the derivative of ``p``
77: (0) - ``p.integ()`` -- Integrate ``p``
78: (0) Validation
79: (0) -----
80: (0) - ``Poly.has_samecoef(p1, p2)`` -- Check if coefficients match
81: (0) - ``Poly.has_samedomain(p1, p2)`` -- Check if domains match
82: (0) - ``Poly.has_sametype(p1, p2)`` -- Check if types match
83: (0) - ``Poly.has_samewindow(p1, p2)`` -- Check if windows match
84: (0) Misc
85: (0) -----
86: (0) - ``p.linspace()`` -- Return ``x, p(x)`` at equally-spaced points in
``domain``
87: (0) - ``p.mapparms()`` -- Return the parameters for the linear mapping between
``domain`` and ``window``.
88: (2)
89: (0) - ``p.roots()`` -- Return the roots of `p`.
90: (0) - ``p.trim()`` -- Remove trailing coefficients.
91: (0) - ``p.cutdeg(degree)`` -- Truncate p to given degree
92: (0) - ``ptruncate(size)`` -- Truncate p to given size
93: (0) """
94: (0)     from .polynomial import Polynomial

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

102: (4)         "polynomial", "Polynomial",
103: (4)         "chebyshev", "Chebyshev",
104: (4)         "legendre", "Legendre",
105: (4)         "hermite", "Hermite",
106: (4)         "hermite_e", "HermiteE",
107: (4)         "laguerre", "Laguerre",
108: (0)
109: (0)     ]
110: (4)     def set_default_printstyle(style):
111: (4)         """
112: (4)             Set the default format for the string representation of polynomials.
113: (4)             Values for ``style`` must be valid inputs to ``__format__``, i.e. 'ascii'
114: (4)             or 'unicode'.
115: (4)             Parameters
116: (4)             -----
117: (4)             style : str
118: (8)                 Format string for default printing style. Must be either 'ascii' or
119: (4)                 'unicode'.
120: (4)             Notes
121: (4)             -----
122: (4)                 The default format depends on the platform: 'unicode' is used on
123: (4)                 Unix-based systems and 'ascii' on Windows. This determination is based on
124: (4)                 default font support for the unicode superscript and subscript ranges.
125: (4)             Examples
126: (4)             -----
127: (4)             >>> p = np.polynomial.Polynomial([1, 2, 3])
128: (4)             >>> c = np.polynomial.Chebyshev([1, 2, 3])
129: (4)             >>> np.polynomial.set_default_printstyle('unicode')
130: (4)             >>> print(p)

164: (8)                                """
165: (4)                                Raises an AssertionError if two objects are not equal.
166: (4)                                Given two objects (scalars, lists, tuples, dictionaries or numpy arrays),
167: (4)                                check that all elements of these objects are equal. An exception is raised
168: (4)                                at the first conflicting values.
169: (4)                                When one of `actual` and `desired` is a scalar and the other is
array_like,
170: (4)                                the function checks that each element of the array_like object is equal to
171: (4)                                the scalar.
172: (4)                                This function handles NaN comparisons as if NaN was a "normal" number.
173: (4)                                That is, AssertionError is not raised if both objects have NaNs in the
same
174: (4)                                positions. This is in contrast to the IEEE standard on NaNs, which says
175: (4)                                that NaN compared to anything must return False.

    -----
    actual : array_like
        The object to check.
    desired : array_like
        The expected object.
    err_msg : str, optional
        The error message to be printed in case of failure.
    verbose : bool, optional
        If True, the conflicting values are appended to the error message.
Raises
-----
AssertionError
    If actual and desired are not equal.
Examples
-----
>>> np.testing.assert_equal([4,5], [4,6])
Traceback (most recent call last):
...
AssertionError:
Items are not equal:
item=1
    ACTUAL: 5
    DESIRED: 6
The following comparison does not raise an exception. There are NaNs
in the inputs, but they are in the same positions.
>>> np.testing.assert_equal(np.array([1.0, 2.0, np.nan]), [1, 2, np.nan])

625: (8)             raise ValueError(msg)
626: (0)           def assert_array_equal(x, y, err_msg='', verbose=True, *, strict=False):
627: (4)             """
628: (4)             Raises an AssertionError if two array_like objects are not equal.
629: (4)             Given two array_like objects, check that the shape is equal and all
630: (4)             elements of these objects are equal (but see the Notes for the special
631: (4)             handling of a scalar). An exception is raised at shape mismatch or
632: (4)             conflicting values. In contrast to the standard usage in numpy, NaNs
633: (4)             are compared like numbers, no assertion is raised if both objects have
634: (4)             NaNs in the same positions.
635: (4)             The usual caution for verifying equality with floating point numbers is
636: (4)             advised.
637: (4)             Parameters
638: (4)             -----
639: (4)             x : array_like
640: (8)               The actual object to check.
641: (4)             y : array_like
642: (8)               The desired, expected object.
643: (4)             err_msg : str, optional
644: (8)               The error message to be printed in case of failure.
645: (4)             verbose : bool, optional
646: (8)               If True, the conflicting values are appended to the error message.
647: (4)             strict : bool, optional
648: (8)               If True, raise an AssertionError when either the shape or the data
649: (8)               type of the array_like objects does not match. The special
650: (8)               handling for scalars mentioned in the Notes section is disabled.
651: (8)               .. versionadded:: 1.24.0
652: (4)             Raises
653: (4)             -----

```

```

654: (4)           AssertionError
655: (8)             If actual and desired objects are not equal.
656: (4)           See Also
657: (4)             -----
658: (4)               assert_allclose: Compare two array_like objects for equality with desired
659: (21)                 relative and/or absolute precision.
660: (4)               assert_array_almost_equal_nulp, assert_array_max_ulp, assert_equal
661: (4)           Notes
662: (4)             -----
663: (4)               When one of `x` and `y` is a scalar and the other is array_like, the
664: (4)                 function checks that each element of the array_like object is equal to
665: (4)                 the scalar. This behaviour can be disabled with the `strict` parameter.
666: (4)           Examples
667: (4)             -----
668: (4)               The first assert does not raise an exception:
669: (4)                 >>> np.testing.assert_array_equal([1.0, 2.33333, np.nan],
670: (4)                               ...                           [np.exp(0), 2.33333, np.nan])
671: (4)               Assert fails with numerical imprecision with floats:
672: (4)                 >>> np.testing.assert_array_equal([1.0, np.pi, np.nan],
673: (4)                               ...                           [1, np.sqrt(np.pi)**2, np.nan])
674: (4)               Traceback (most recent call last):
675: (8)                 ...
676: (4)           AssertionError:
677: (4)             Arrays are not equal
678: (4)             <BLANKLINE>
679: (4)               Mismatched elements: 1 / 3 (33.3%)
680: (4)               Max absolute difference: 4.4408921e-16
681: (4)               Max relative difference: 1.41357986e-16
682: (5)                 x: array([1.          , 3.141593,       nan])
683: (5)                 y: array([1.          , 3.141593,       nan])
684: (4)               Use `assert_allclose` or one of the nulp (number of floating point values)
685: (4)               functions for these cases instead:
686: (4)                 >>> np.testing.assert_allclose([1.0, np.pi, np.nan],
687: (4)                               ...                           [1, np.sqrt(np.pi)**2, np.nan],
688: (4)                               ...                           rtol=1e-10, atol=0)
689: (4)               As mentioned in the Notes section, `assert_array_equal` has special
690: (4)               handling for scalars. Here the test checks that each value in `x` is 3:
691: (4)                 >>> x = np.full((2, 5), fill_value=3)
692: (4)                 >>> np.testing.assert_array_equal(x, 3)
693: (4)               Use `strict` to raise an AssertionError when comparing a scalar with an
694: (4)               array:
695: (4)                 >>> np.testing.assert_array_equal(x, 3, strict=True)
696: (4)               Traceback (most recent call last):
697: (8)                 ...
698: (4)           AssertionError:
699: (4)             Arrays are not equal
700: (4)             <BLANKLINE>
701: (4)               (shapes (2, 5), () mismatch)
702: (5)                 x: array([[3, 3, 3, 3, 3],
703: (11)                   [3, 3, 3, 3, 3]])
704: (5)                 y: array(3)
705: (4)               The `strict` parameter also ensures that the array data types match:
706: (4)                 >>> x = np.array([2, 2, 2])
707: (4)                 >>> y = np.array([2., 2., 2.], dtype=np.float32)
708: (4)                 >>> np.testing.assert_array_equal(x, y, strict=True)
709: (4)               Traceback (most recent call last):
710: (8)                 ...
711: (4)           AssertionError:
712: (4)             Arrays are not equal
713: (4)             <BLANKLINE>
714: (4)               (dtypes int64, float32 mismatch)
715: (5)                 x: array([2, 2, 2])
716: (5)                 y: array([2., 2., 2.], dtype=float32)
717: (4)               """

def assert_array_almost_equal(x, y, decimal=6, err_msg='', verbose=True):
    """
    Raises an AssertionError if two objects are not equal up to desired
    precision.
    .. note:: It is recommended to use one of `assert_allclose`,
              `assert_array_almost_equal_nulp` or `assert_array_max_ulp`
              instead of this function for more consistent floating point
              comparisons.
    The test verifies identical shapes and that the elements of ``actual`` and
    ``desired`` satisfy.
        ``abs(desired-actual) < 1.5 * 10**(-decimal)``
    That is a looser test than originally documented, but agrees with what the
    actual implementation did up to rounding vagaries. An exception is raised
    at shape mismatch or conflicting values. In contrast to the standard usage
    in numpy, NaNs are compared like numbers, no assertion is raised if both
    objects have NaNs in the same positions.
    Parameters
    -----
    x : array_like
        The actual object to check.
    y : array_like
        The desired, expected object.
    decimal : int, optional
        Desired precision, default is 6.
    err_msg : str, optional
        The error message to be printed in case of failure.
    verbose : bool, optional
        If True, the conflicting values are appended to the error message.
    Raises
    -----
    AssertionError
        If actual and desired are not equal up to specified precision.
    See Also
    -----
    assert_allclose: Compare two array_like objects for equality with desired
                    relative and/or absolute precision.
    assert_array_almost_equal_nulp, assert_array_max_ulp, assert_equal
    Examples
    -----
    the first assert does not raise an exception
    >>> np.testing.assert_array_almost_equal([1.0,2.333,np.nan],
...                                     [1.0,2.333,np.nan])
    >>> np.testing.assert_array_almost_equal([1.0,2.33333,np.nan],
...                                     [1.0,2.33339,np.nan], decimal=5)
    Traceback (most recent call last):
    ...
    AssertionError:
    Arrays are not almost equal to 5 decimals

def assert_array_less(x, y, err_msg='', verbose=True):
    """
    Raises an AssertionError if two array_like objects are not ordered by less
    than.
    Given two array_like objects, check that the shape is equal and all
    elements of the first object are strictly smaller than those of the
    second object. An exception is raised at shape mismatch or incorrectly
    ordered values. Shape mismatch does not raise if an object has zero
    dimension. In contrast to the standard usage in numpy, NaNs are
    compared, no assertion is raised if both objects have NaNs in the same
    positions.
    Parameters
    -----
    x : array_like
        The smaller object to check.
    y : array_like
        The larger object to compare.
    err_msg : string
        The error message to be printed in case of failure.
    verbose : bool
        If True, the conflicting values are appended to the error message.
    Raises
    -----
    AssertionError
        If x is not strictly smaller than y, element-wise.

def measure(code_str, times=1, label=None):
    """
    Return elapsed time for executing code in the namespace of the caller.
    The supplied code string is compiled with the Python builtin ``compile``.
    The precision of the timing is 10 milli-seconds. If the code will execute
    fast on this timescale, it can be executed many times to get reasonable
    timing accuracy.
    Parameters
    -----
    code_str : str
        The code to be timed.
    times : int, optional
        The number of times the code is executed. Default is 1. The code is
        only compiled once.
    label : str, optional
        A label to identify `code_str` with. This is passed into ``compile``

        as the second argument (for run-time error messages).
    Returns
    -----
    elapsed : float
        Total elapsed time in seconds for executing `code_str` `times` times.
    Examples
    -----
    >>> times = 10
    >>> etime = np.testing.measure('for i in range(1000): np.sqrt(i**2)',

Notes).

```

err\_msg='', verbose=True):

"""

Raises an AssertionError if two objects are not equal up to desired tolerance.

Given two array\_like objects, check that their shapes and all elements are equal (but see the Notes for the special handling of a scalar). An exception is raised if the shapes mismatch or any values conflict. In contrast to the standard usage in numpy, NaNs are compared like numbers, no assertion is raised if both objects have NaNs in the same positions. The test is equivalent to ``allclose(actual, desired, rtol, atol)`` (note that ``allclose`` has different default values). It compares the difference between `actual` and `desired` to ``atol + rtol \* abs(desired)``.

.. versionadded:: 1.5.0

Parameters

-----

actual : array\_like  
    Array obtained.

desired : array\_like  
    Array desired.

rtol : float, optional  
    Relative tolerance.

atol : float, optional  
    Absolute tolerance.

equal\_nan : bool, optional.  
    If True, NaNs will compare equal.

err\_msg : str, optional  
    The error message to be printed in case of failure.

verbose : bool, optional  
    If True, the conflicting values are appended to the error message.

Raises

-----

AssertionError  
    If actual and desired are not equal up to specified precision.

See Also

-----

assert\_array\_almost\_equal\_nulp, assert\_array\_max\_ulp

Notes

-----

When one of `actual` and `desired` is a scalar and the other is array\_like, the function checks that each element of the array\_like object is equal to the scalar.

Examples

-----

```

>>> x = [1e-5, 1e-3, 1e-1]
>>> y = np.arccos(np.cos(x))
>>> np.testing.assert_allclose(x, y, rtol=1e-5, atol=0)
"""
__tracebackhide__ = True # Hide traceback for py.test

    return np.core.numeric.isclose(x, y, rtol=rtol, atol=atol,
                                    equal_nan=equal_nan)
actual, desired = np.asanyarray(actual), np.asanyarray(desired)
header = f'Not equal to tolerance rtol={rtol:g}, atol={atol:g}'
assert_array_compare(compare, actual, desired, err_msg=str(err_msg),
                      verbose=verbose, header=header, equal_nan=equal_nan)

```

def assert\_array\_almost\_equal\_nulp(x, y, nulp=1):

"""

Compare two arrays relatively to their spacing.

This is a relatively robust method to compare two arrays whose amplitude is variable.

Parameters

-----

x, y : array\_like  
    Input arrays.

nulp : int, optional  
    The maximum number of unit in the last place for tolerance (see Notes).

1534: (8)                     os.remove(path)
1535: (0)             class clear_and_catch_warnings(warnings.catch_warnings):
1536: (4)                 """ Context manager that resets warning registry for catching warnings
1537: (4)                 Warnings can be slippery, because, whenever a warning is triggered, Python
1538: (4)                 adds a ``__warningregistry__`` member to the *calling* module. This makes
1539: (4)                 it impossible to retrigger the warning in this module, whatever you put in
1540: (4)                 the warnings filters. This context manager accepts a sequence of

```

```

`modules`
1541: (4)           as a keyword argument to its constructor and:
1542: (4)           * stores and removes any ``__warningregistry__`` entries in given
`modules`
1543: (6)           on entry;
1544: (4)           * resets ``__warningregistry__`` to its previous state on exit.
1545: (4)           This makes it possible to trigger any warning afresh inside the context
1546: (4)           manager without disturbing the state of warnings outside.
1547: (4)           For compatibility with Python 3.0, please consider all arguments to be
1548: (4)           keyword-only.
1549: (4)           Parameters
1550: (4)           -----
1551: (4)           record : bool, optional
1552: (8)             Specifies whether warnings should be captured by a custom
1553: (8)             implementation of ``warnings.showwarning()`` and be appended to a list
1554: (8)             returned by the context manager. Otherwise None is returned by the
1555: (8)             context manager. The objects appended to the list are arguments whose
1556: (8)             attributes mirror the arguments to ``showwarning()``.
1557: (4)           modules : sequence, optional
1558: (8)             Sequence of modules for which to reset warnings registry on entry and
1559: (8)             restore on exit. To work correctly, all 'ignore' filters should
1560: (8)             filter by one of these modules.
1561: (4)           Examples
1562: (4)           -----
1563: (4)           >>> import warnings
1564: (4)           >>> with np.testing.clear_and_catch_warnings(
1565: (4)             ...         modules=[np.core.fromnumeric]):
1566: (4)             ...         warnings.simplefilter('always')
1567: (4)             ...         warnings.filterwarnings('ignore', module='np.core.fromnumeric')
1568: (4)             ...         # do something that raises a warning but ignore those in
1569: (4)             ...         # np.core.fromnumeric
1570: (4)             """

1584: (8)               super().__exit__(*exc_info)
1585: (8)               for mod in self.modules:
1586: (12)                 if hasattr(mod, '__warningregistry__'):
1587: (16)                   mod.__warningregistry__.clear()
1588: (12)                   if mod in self._warnreg_copies:
1589: (16)                       mod.__warningregistry__.update(self._warnreg_copies[mod])
1590: (0)
1591: (4)           class suppress_warnings:
1592: (4)             """
1593: (4)               Context manager and decorator doing much the same as
1594: (4)               ``warnings.catch_warnings``.
1595: (4)               However, it also provides a filter mechanism to work around
1596: (4)               https://bugs.python.org/issue4180.
1597: (4)               This bug causes Python before 3.4 to not reliably show warnings again
1598: (4)               after they have been ignored once (even within catch_warnings). It
1599: (4)               means that no "ignore" filter can be used easily, since following
1600: (4)               tests might need to see the warning. Additionally it allows easier
1601: (4)               specificity for testing warnings and can be nested.
1602: (4)               Parameters
1603: (4)               -----
1604: (8)               forwarding_rule : str, optional
1605: (8)                 One of "always", "once", "module", or "location". Analogous to
1606: (8)                 the usual warnings module filter mode, it is useful to reduce
1607: (8)                 noise mostly on the outmost level. Unsuppressed and unrecorded

```

```

1608: (8)           "location" is equivalent to the warnings "default", match by exact
1609: (8)           location the warning originated from.
1610: (4)           Notes
1611: (4)
1612: (4)           -----
1613: (4)           Filters added inside the context manager will be discarded again
1614: (4)           when leaving it. Upon entering all filters defined outside a
1615: (4)           context will be applied automatically.
1616: (4)           When a recording filter is added, matching warnings are stored in the
1617: (4)           ``log`` attribute as well as in the list returned by ``record``.
1618: (4)           If filters are added and the ``module`` keyword is given, the
1619: (4)           warning registry of this module will additionally be cleared when
1620: (4)           applying it, entering the context, or exiting it. This could cause
1621: (4)           warnings to appear a second time after leaving the context if they
1622: (4)           were configured to be printed once (default) and were already
1623: (4)           printed before the context was entered.
1624: (4)           Nesting this context manager will work as expected when the
1625: (4)           forwarding rule is "always" (default). Unfiltered and unrecorded
1626: (4)           warnings will be passed out and be matched by the outer level.
1627: (4)           On the outmost level they will be printed (or caught by another
1628: (4)           warnings context). The forwarding rule argument can modify this
1629: (4)           behaviour.
1630: (4)           Like ``catch_warnings`` this context manager is not threadsafe.
1631: (4)           Examples
1632: (4)
1633: (4)           With a context manager::
1634: (8)             with np.testing.suppress_warnings() as sup:
1635: (12)               sup.filter(DeprecationWarning, "Some text")
1636: (12)               sup.filter(module=np.ma.core)
1637: (12)               log = sup.record(FutureWarning, "Does this occur?")
1638: (12)               command_giving_warnings()
1639: (12)               assert_(len(log) == 1)
1640: (4)               assert_(len(sup.log) == 1) # also stored in log attribute
1641: (4)           Or as a decorator::
1642: (8)             sup = np.testing.suppress_warnings()
1643: (8)             sup.filter(module=np.ma.core) # module must match exactly

        Method checking all objects. The pkgutil-based method in
        `test_all_modules_are_expected` does not catch imports into a namespace,
        only filenames. So this test is more thorough, and checks this like:
            import .lib.scimath as emath
        To check if something in a module is (effectively) public, one can check
        there's anything in that namespace that's a public function/object but is
        not exposed in a higher-level namespace. For example for a `numpy.lib`
        submodule::
            mod = np.lib.mixins
            for obj in mod.__all__:
                if obj in np.__all__:
                    continue
                elif obj in np.lib.__all__:
                    continue
                else:

File 346 - mypy\_plugin.py:

```

1: (0)         """A mypy_ plugin for managing a number of platform-specific annotations.
2: (0)         Its functionality can be split into three distinct parts:
3: (0)         * Assigning the (platform-dependent) precisions of certain `~numpy.number`_
4: (2)             subclasses, including the likes of `~numpy.int_`, `~numpy.intp` and
5: (2)             `~numpy.longlong`. See the documentation on
6: (2)             :ref:`scalar types <arrays.scalars.built-in>` for a comprehensive overview
7: (2)             of the affected classes. Without the plugin the precision of all relevant
8: (2)             classes will be inferred as `~typing.Any`_.
9: (0)         * Removing all extended-precision `~numpy.number`_ subclasses that are
10: (2)             unavailable for the platform in question. Most notably this includes the
11: (2)             likes of `~numpy.float128` and `~numpy.complex256`. Without the plugin *all*
12: (2)             extended-precision types will, as far as mypy is concerned, be available
13: (2)             to all platforms.
14: (0)         * Assigning the (platform-dependent) precision of `~numpy.ctypeslib.c_intp`_.
15: (2)             Without the plugin the type will default to `ctypes.c_int64`_.
16: (2)             .. versionadded:: 1.22

=====

Typing (:mod:`numpy.typing`)

=====
.. versionadded:: 1.20

Large parts of the NumPy API have :pep:`484`-style type annotations. In addition a number of type aliases are available to users, most prominently the two below:

- `ArrayLike`: objects that can be converted to arrays
- `DTypeLike`: objects that can be converted to dtypes

.. \_typing-extensions: <https://pypi.org/project/typing-extensions/>

Mypy plugin

-----
.. versionadded:: 1.21

.. automodule:: numpy.typing.mypy\_plugin

.. currentmodule:: numpy.typing

Differences from the runtime NumPy API

-----
NumPy is very flexible. Trying to describe the full range of possibilities statically would result in types that are not very helpful. For that reason, the typed NumPy API is often stricter than the runtime NumPy API. This section describes some notable differences.

ArrayLike

~~~~~

The `ArrayLike` type tries to avoid creating object arrays. For example,

.. code-block:: python

```
>>> np.array(x**2 for x in range(10))
array(<generator object <genexpr> at ...>, dtype=object)
```

is valid NumPy code which will create a 0-dimensional object array. Type checkers will complain about the above example when using the NumPy types however. If you really intended to do the above, then you can either use a ``# type: ignore`` comment:

.. code-block:: python

```
>>> np.array(x**2 for x in range(10)) # type: ignore
```

or explicitly type the array like object as `~typing.Any`:

.. code-block:: python

```
>>> from typing import Any
>>> array_like: Any = (x**2 for x in range(10))
>>> np.array(array_like)
array(<generator object <genexpr> at ...>, dtype=object)
```

ndarray

~~~~~

It's possible to mutate the dtype of an array at runtime. For example, the following code is valid:

.. code-block:: python

```
>>> x = np.array([1, 2])
>>> x.dtype = np.bool_
```

This sort of mutation is not allowed by the types. Users who want to write statically typed code should instead use the `numpy.ndarray.view` method to create a view of the array with a different dtype.

DTypeLike

~~~~~

The `DTypeLike` type tries to avoid creation of dtype objects using dictionary of fields like below:

.. code-block:: python

```
>>> x = np.dtype({"field1": (float, 1), "field2": (int, 3)})
```

Although this is valid NumPy code, the type checker will complain about it, since its usage is discouraged.

Please see :ref:`Data type objects <arrays.dtypes>`

Number precision

~~~~~

The precision of `numpy.number` subclasses is treated as a covariant generic parameter (see :class:`~NBitBase`), simplifying the annotating of processes involving precision-based casting.

.. code-block:: python

```
>>> from typing import TypeVar
>>> import numpy as np
```

```

70: (4)          >>> import numpy.typing as npt
71: (4)          >>> T = TypeVar("T", bound=npt.NBitBase)
72: (4)          >>> def func(a: "np.floating[T]", b: "np.floating[T]") ->
73: (4)              ...
74: (0)      ... Consequently, the likes of `~numpy.float16`, `~numpy.float32` and
75: (0)      `~numpy.float64` are still sub-types of `~numpy.floating`, but, contrary to
76: (0)      runtime, they're not necessarily considered as sub-classes.
77: (0)      Timedelta64
78: (0)      ~~~~~
79: (0)      The `~numpy.timedelta64` class is not considered a subclass of
80: (0)      `~numpy.signedinteger`, the former only inheriting from `~numpy.generic`
81: (0)      while static type checking.
82: (0)      0D arrays
83: (0)      ~~~~~
84: (0)      During runtime numpy aggressively casts any passed 0D arrays into their
85: (0)      corresponding `~numpy.generic` instance. Until the introduction of shape
86: (0)      typing (see :pep:`646`) it is unfortunately not possible to make the
87: (0)      necessary distinction between 0D and >0D arrays. While thus not strictly
88: (0)      correct, all operations are that can potentially perform a 0D-array -> scalar
89: (0)      cast are currently annotated as exclusively returning an `ndarray`.
90: (0)      If it is known in advance that an operation _will_ perform a
91: (0)      0D-array -> scalar cast, then one can consider manually remedying the
92: (0)      situation with either `typing.cast` or a ``# type: ignore`` comment.
93: (0)      Record array dtypes
94: (0)      ~~~~~
95: (0)      The dtype of `numpy.recarray`, and the `numpy.rec` functions in general,
96: (0)      can be specified in one of two ways:
97: (0)          * Directly via the ``dtype`` argument.
98: (0)          * With up to five helper arguments that operate via `numpy.format_parser`:
99: (2)              ``formats``, ``names``, ``titles``, ``aligned`` and ``byteorder``.
100: (0)      These two approaches are currently typed as being mutually exclusive,
101: (0)          *i.e.* if ``dtype`` is specified than one may not specify ``formats``.
102: (0)      While this mutual exclusivity is not (strictly) enforced during runtime,
103: (0)      combining both dtype specifiers can lead to unexpected or even downright
104: (0)      buggy behavior.
105: (0)      API

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY_combined_python_files_20_chars.txt

8: (0)
9: (4)
10: (4)        A type representing `numpy.number` precision during static type checking.
11: (4)        Used exclusively for the purpose static type checking, `NBitBase`
12: (4)        represents the base of a hierarchical set of subclasses.
13: (4)        Each subsequent subclass is herein used for representing a lower level
14: (4)        of precision, *e.g.* ``64Bit > 32Bit > 16Bit``.
15: (4)        .. versionadded:: 1.20
16: (4)        Examples
17: (4)        -----
18: (4)        Below is a typical usage example: `NBitBase` is herein used for annotating
19: (4)        a function that takes a float and integer of arbitrary precision
20: (4)        as arguments and returns a new float of whichever precision is largest
21: (4)        (*e.g.* ``np.float16 + np.int64 -> np.float64``).
22: (4)        .. code-block:: python
23: (8)            >>> from __future__ import annotations
24: (8)            >>> from typing import TypeVar, TYPE_CHECKING
