## File 2 - ctypeslib.py:

```

1: (0)             """
2: (0)             =====
3: (0)             ``ctypes`` Utility Functions
4: (0)             =====
5: (0)             See Also
6: (0)             -----
7: (0)             load_library : Load a C library.
8: (0)             ndpointer : Array restype/argtype with verification.
9: (0)             as_ctypes : Create a ctypes array from an ndarray.
10: (0)            as_array : Create an ndarray from a ctypes array.
11: (0)            References
12: (0)            -----
13: (0)            .. [1] "SciPy Cookbook: ctypes", https://scipy-
cookbook.readthedocs.io/items/Ctypes.html
14: (0)            Examples
15: (0)            -----
16: (0)            Load the C library:
17: (0)            >>> _lib = np.ctypeslib.load_library('libmystuff', '.')      #doctest: +SKIP
18: (0)            Our result type, an ndarray that must be of type double, be 1-dimensional
19: (0)            and is C-contiguous in memory:
20: (0)            >>> array_1d_double = np.ctypeslib.ndpointer(
21: (0)                ...
22: (0)                dtype=np.double,
23: (0)                ...
24: (0)                ndim=1, flags='CONTIGUOUS')      #doctest: +SKIP
25: (0)            Our C-function typically takes an array and updates its values
26: (0)            in-place. For example::
27: (4)                void foo_func(double* x, int length)
28: (4)                {
29: (8)                    int i;

```

```

28: (8)           for (i = 0; i < length; i++) {
29: (12)             x[i] = i*i;
30: (8)         }
31: (4)     }
32: (0)   We wrap it using:
33: (0)   >>> _lib.foo_func.restype = None          #doctest: +SKIP
34: (0)   >>> _lib.foo_func.argtypes = [array_1d_double, c_int] #doctest: +SKIP
35: (0)   Then, we're ready to call ``foo_func``:
36: (0)   >>> out = np.empty(15, dtype=np.double)
37: (0)   >>> _lib.foo_func(out, len(out))          #doctest: +SKIP
38: (0)
39: (0)   """

```

9: (0) .. versionadded:: NumPy 1.25
10: (4)     The dtypes module is new in NumPy 1.25. Previously Dtype classes were
11: (4)     only accessible indirectly.
12: (0) Dtype classes
13: (0) -----
14: (0)     The following are the classes of the corresponding NumPy dtype instances and
15: (0)     NumPy scalar types. The classes can be used in ``isinstance`` checks and can
16: (0)     also be instantiated or used directly. Direct use of these classes is not
17: (0)     typical, since their scalar counterparts (e.g. ``np.float64``) or strings
18: (0)     like ``"float64"`` can be used.

59: (4)            """Axis supplied was invalid.
60: (4)            This is raised whenever an ``axis`` parameter is specified that is larger
61: (4)            than the number of array dimensions.
62: (4)            For compatibility with code written against older numpy versions, which
63: (4)            raised a mixture of `ValueError` and `IndexError` for this situation, this
64: (4)            exception subclasses both to ensure that ``except ValueError`` and
65: (4)            ``except IndexError`` statements continue to catch `AxisError`.
66: (4)            .. versionadded:: 1.13
67: (4)            Parameters
68: (4)            -----
69: (4)            axis : int or str
70: (8)              The out of bounds axis or a custom exception message.
71: (8)              If an axis is provided, then `ndim` should be specified as well.
72: (4)            ndim : int, optional
73: (8)              The number of array dimensions.
74: (4)            msg_prefix : str, optional
75: (8)              A prefix for the exception message.
76: (4)            Attributes
77: (4)            -----
78: (4)            axis : int, optional
79: (8)              The out of bounds axis or ``None`` if a custom exception
80: (8)              message was provided. This should be the axis as passed by
81: (8)              the user, before any normalization to resolve negative indices.
82: (4)              .. versionadded:: 1.22
83: (4)            ndim : int, optional
84: (8)              The number of array dimensions or ``None`` if a custom exception
85: (8)              message was provided.
86: (4)              .. versionadded:: 1.22

```

```

90: (4) Examples
91: (4) -----
92: (4) >>> array_1d = np.arange(10)
93: (4) >>> np.cumsum(array_1d, axis=1)
94: (4) Traceback (most recent call last):
95: (6) ...
96: (4) numpy.exceptions.AxisError: axis 1 is out of bounds for array of dimension
1
97: (4) Negative axes are preserved:
98: (4) >>> np.cumsum(array_1d, axis=-2)
99: (4) Traceback (most recent call last):
100: (6) ...
101: (4) numpy.exceptions.AxisError: axis -2 is out of bounds for array of
dimension 1
102: (4) The class constructor generally takes the axis and arrays'
103: (4) dimensionality as arguments:
104: (4) >>> print(np.AxisError(2, 1, msg_prefix='error'))
105: (4) error: axis 2 is out of bounds for array of dimension 1
106: (4) Alternatively, a custom exception message can be passed:
107: (4) >>> print(np.AxisError('Custom error message'))
108: (4) Custom error message
109: (4) """
110: (4) __slots__ = ("axis", "ndim", "_msg")
111: (4) def __init__(self, axis, ndim=None, msg_prefix=None):
112: (8)     if ndim is msg_prefix is None:
113: (12)         self._msg = axis
114: (12)         self.axis = None
115: (12)         self.ndim = None
116: (8)     else:
117: (12)         self._msg = msg_prefix
118: (12)         self.axis = axis
119: (12)         self.ndim = ndim
120: (4) def __str__(self):
121: (8)     axis = self.axis
122: (8)     ndim = self.ndim
123: (8)     if axis is ndim is None:
124: (12)         return self._msg
125: (8)     else:
126: (12)         msg = f"axis {axis} is out of bounds for array of dimension
{ndim}"
127: (12)         if self._msg is not None:
128: (16)             msg = f"{self._msg}: {msg}"
129: (12)         return msg
130: (0) class DtypePromotionError(TypeError):
131: (4)     """Multiple DTypes could not be converted to a common one.
132: (4)     This exception derives from ``TypeError`` and is raised whenever dtypes
133: (4)     cannot be converted to a single common one. This can be because they
134: (4)     are of a different category/class or incompatible instances of the same
135: (4)     one (see Examples).
136: (4) Notes
137: (4) -----
138: (4) Many functions will use promotion to find the correct result and
139: (4) implementation. For these functions the error will typically be chained
140: (4) with a more specific error indicating that no implementation was found
141: (4) for the input dtypes.
142: (4) Typically promotion should be considered "invalid" between the dtypes of
143: (4) two arrays when `arr1 == arr2` can safely return all ``False`` because the
144: (4) dtypes are fundamentally different.
145: (4) Examples
146: (4) -----
147: (4) Datetimes and complex numbers are incompatible classes and cannot be
148: (4) promoted:
149: (4) >>> np.result_type(np.dtype("M8[s]"), np.complex128)
150: (4) DtypePromotionError: The Dtype <class 'numpy.dtype[datetime64]'> could not
151: (4) be promoted by <class 'numpy.dtype[complex128]'>. This means that no
common
152: (4) Dtype exists for the given inputs. For example they cannot be stored in a
153: (4) single array unless the dtype is `object`. The full list of DTypes is:
154: (4) (<class 'numpy.dtype[datetime64]'>, <class 'numpy.dtype[complex128]'>)

```

```

155: (4)          For example for structured dtypes, the structure can mismatch and the
156: (4)          same ``DTypePromotionError`` is given when two structured dtypes with
157: (4)          a mismatch in their number of fields is given:
158: (4)          >>> dtype1 = np.dtype([("field1", np.float64), ("field2", np.int64)])
159: (4)          >>> dtype2 = np.dtype([("field1", np.float64)])
160: (4)          >>> np.promote_types(dtype1, dtype2)
161: (4)          DTypePromotionError: field names `('field1', 'field2')` and `('field1',)`
162: (4)          mismatch.
163: (4)          """
164: (4)          pass
-----
```

## File 5 - matlib.py:

-----  

n : int  

    Size of the returned identity matrix.  

dtype : data-type, optional  

    Data-type of the output. Defaults to ``float``.  

Returns  

-----  

out : matrix  

    `n` x `n` matrix with its main diagonal set to one,  

    and all other elements zero.  

See Also  

-----  

numpy.identity : Equivalent array function.  

matlib.eye : More general matrix identity function.  

Examples  

-----  

>>> import numpy.matlib  

>>> np.matlib.identity(3, dtype=int)  

matrix([[1, 0, 0],  

       [0, 1, 0],  

       [0, 0, 1]])  

"""  

a = array([1]+n*[0], dtype=dtype)  

b = empty((n, n), dtype=dtype)  

b.flat = a  

return b  

def eye(n,M=None, k=0, dtype=float, order='C'):  

"""
    Return a matrix with ones on the diagonal and zeros elsewhere.  

Parameters  

-----  

n : int  

    Number of rows in the output.  

M : int, optional  

    Number of columns in the output, defaults to `n`.  

k : int, optional  

    Index of the diagonal: 0 refers to the main diagonal,  

    a positive value refers to an upper diagonal,  

    and a negative value to a lower diagonal.  

dtype : dtype, optional  

    Data-type of the returned matrix.  

order : {'C', 'F'}, optional  

    Whether the output should be stored in row-major (C-style) or  

    column-major (Fortran-style) order in memory.  

.. versionadded:: 1.14.0  

Returns  

-----  

I : matrix  

    A `n` x `M` matrix where all elements are equal to zero,  

    except for the `k`-th diagonal, whose values are equal to one.  

See Also  

-----  

numpy.eye : Equivalent array function.  

identity : Square identity matrix.  

Examples  

-----  

>>> import numpy.matlib  

>>> np.matlib.eye(3, k=1, dtype=float)  

matrix([[0., 1., 0.],  

       [0., 0., 1.],

```

## File 9 - \_pytesttester.py:

```

1: (0)             """
2: (0)             Pytest test running.
3: (0)             This module implements the ``test()`` function for NumPy modules. The usual
4: (0)             boiler plate for doing that is to put the following in the module
5: (0)             ``__init__.py`` file::
6: (4)                 from numpy._pytesttester import PytestTester
7: (4)                 test = PytestTester(__name__)
8: (4)                 del PytestTester
9: (0)             Warnings filtering and other runtime settings should be dealt with in the
10: (0)             ``pytest.ini`` file in the numpy repo root. The behavior of the test depends
on
11: (0)             whether or not that file is found as follows:
12: (0)             * ``pytest.ini`` is present (develop mode)
13: (4)                 All warnings except those explicitly filtered out are raised as error.
14: (0)             * ``pytest.ini`` is absent (release mode)
15: (4)                 DeprecationWarnings and PendingDeprecationWarnings are ignored, other
16: (4)                 warnings are passed through.
17: (0)             In practice, tests run from the numpy repo are run in develop mode. That
18: (0)             includes the standard ``python runtests.py`` invocation.
19: (0)             This module is imported by every numpy subpackage, so lies at the top level to
20: (0)             simplify circular import issues. For the same reason, it contains no numpy
21: (0)             imports at module scope, instead importing numpy within function calls.
22: (0)
23: (0)             import sys
24: (0)             import os
25: (0)             __all__ = ['PytestTester']
26: (0)             def _show_numpy_info():
27: (4)                 import numpy as np
28: (4)                 print("NumPy version %s" % np.__version__)
29: (4)                 relaxed_strides = np.ones((10, 1), order="C").flags.f_contiguous
30: (4)                 print("NumPy relaxed strides checking option:", relaxed_strides)
31: (4)                 info = np.lib.utils._opt_info()
32: (4)                 print("NumPy CPU features: ", (info if info else 'nothing enabled'))
33: (0)             class PytestTester:
34: (4)                 """
35: (4)                 Pytest test runner.
36: (4)                 A test function is typically added to a package's __init__.py like so::
37: (6)                     from numpy._pytesttester import PytestTester
38: (6)                     test = PytestTester(__name__).test
39: (6)                     del PytestTester
40: (4)                 Calling this test function finds and runs all tests associated with the
41: (4)                 module and all its sub-modules.
42: (4)                 Attributes
43: (4)                 -----
44: (4)                 module_name : str
45: (8)                     Full path to the package to test.
46: (4)                 Parameters
47: (4)                 -----
48: (4)                 module_name : module name
49: (8)                     The name of the module to test.
50: (4)                 Notes
51: (4)                 -----
52: (4)                 Unlike the previous ``nose``-based implementation, this class is not
53: (4)                 publicly exposed as it performs some ``numpy``-specific warning
54: (4)                 suppression.

            Run tests for module using pytest.

            Parameters
            -----
            label : {'fast', 'full'}, optional
                Identifies the tests to run. When set to 'fast', tests decorated
                with `pytest.mark.slow` are skipped, when 'full', the slow marker
                is ignored.
            verbose : int, optional
                Verbosity value for test outputs, in the range 1-3. Default is 1.
            extra_argv : list, optional
                List with any extra arguments to pass to pytests.
            doctests : bool, optional
                .. note:: Not supported
            coverage : bool, optional
                If True, report coverage of NumPy code. Default is False.
                Requires installation of (pip) pytest-cov.
            durations : int, optional
                If < 0, do nothing, If 0, report time of all tests, if > 0,
                report the time of the slowest `timer` tests. Default is -1.
            tests : test or list of tests
                Tests to be executed with pytest '--pyargs'
            Returns
            -----
            result : bool
                Return True on success, false otherwise.
            Notes
            -----
            Each NumPy module exposes `test` in its namespace to run all tests for
            it. For example, to run all tests for numpy.lib:
            >>> np.lib.test() #doctest: +SKIP
            Examples
            -----
            >>> result = np.lib.test() #doctest: +SKIP
            ...
            1023 passed, 2 skipped, 6 deselected, 1 xfailed in 10.39 seconds
            >>> result
            True
            """

**File 11 - \_\_init\_\_.py:**

```

1: (0)             """
2: (0)             NumPy
3: (0)             ====
4: (0)             Provides
5: (2)             1. An array object of arbitrary homogeneous items
6: (2)             2. Fast mathematical operations over arrays
7: (2)             3. Linear Algebra, Fourier Transforms, Random Number Generation
8: (0)             How to use the documentation
9: (0)
10: (0)             -----
11: (0)             Documentation is available in two forms: docstrings provided
12: (0)             with the code, and a loose standing reference guide, available from
13: (0)             `the NumPy homepage <https://numpy.org>`.
14: (0)             We recommend exploring the docstrings using
15: (0)             `IPython <https://ipython.org>`, an advanced Python shell with
16: (0)             TAB-completion and introspection capabilities. See below for further
17: (0)             instructions.
18: (2)             The docstring examples assume that `numpy` has been imported as ``np``::
19: (0)                 >>> import numpy as np
20: (2)             Code snippets are indicated by three greater-than signs::
21: (2)                 >>> x = 42
22: (2)                 >>> x = x + 1
23: (0)             Use the built-in ``help`` function to view a function's docstring::
24: (2)                 >>> help(np.sort)
25: (2)                 ... # doctest: +SKIP
26: (0)             For some objects, ``np.info(obj)`` may provide additional help. This is
27: (0)             particularly true if you see the line "Help on ufunc object:" at the top
28: (0)             of the help() page. Ufuncs are implemented in C, not Python, for speed.

```

```

28: (0)          The native Python help() does not know how to view their help, but our
29: (0)          np.info() function does.
30: (0)          To search for documents containing a keyword, do::
31: (2)            >>> np.lookfor('keyword')
32: (2)            ... # doctest: +SKIP
33: (0)          General-purpose documents like a glossary and help on the basic concepts
34: (0)          of numpy are available under the ``doc`` sub-module::
35: (2)            >>> from numpy import doc
36: (2)            >>> help(doc)
37: (2)            ... # doctest: +SKIP
38: (0)          Available subpackages
39: (0)          -----
40: (0)          lib
41: (4)            Basic functions used by several sub-packages.

64: (4)            NumPy version string
65: (0)          Viewing documentation using IPython
66: (0)          -----
67: (0)          Start IPython and import `numpy` usually under the alias ``np``: `import
68: (0)          numpy as np`. Then, directly past or use the ``%cpaste`` magic to paste
69: (0)          examples into the shell. To see which functions are available in `numpy`,
70: (0)          type ``np.<TAB>`` (where ``<TAB>`` refers to the TAB key), or use
71: (0)          ``np.*cos?<ENTER>`` (where ``<ENTER>`` refers to the ENTER key) to narrow
72: (0)          down the list. To view the docstring for a function, use
73: (0)          ``np.cos?<ENTER>`` (to view the docstring) and ``np.cos??<ENTER>`` (to view
74: (0)          the source code).
75: (0)          Copies vs. in-place operation
76: (0)          -----
77: (0)          Most of the functions in `numpy` return a copy of the array argument
78: (0)          (e.g., `np.sort`). In-place versions of these functions are often
79: (0)          available as array methods, i.e. ``x = np.array([1,2,3]); x.sort()``.
80: (0)          Exceptions to this rule are documented.
81: (0)          """

#### File 14 - \_array\_object.py:

```

1: (0) """
2: (0)     Wrapper class around the ndarray object for the array API standard.
3: (0)     The array API standard defines some behaviors differently than ndarray, in
4: (0)     particular, type promotion rules are different (the standard has no
5: (0)     value-based casting). The standard also specifies a more limited subset of
6: (0)     array methods and functionalities than are implemented on ndarray. Since the
7: (0)     goal of the array_api namespace is to be a minimal implementation of the array
8: (0)     API standard, we need to define a separate wrapper class for the array_api
9: (0)     namespace.
10: (0)    The standard compliant class is only a wrapper class. It is *not* a subclass
11: (0)     of ndarray.
12: (0) """

160: (4)         @staticmethod
161: (4)         def _normalize_two_args(x1, x2) -> Tuple[Array, Array]:
162: (8)             """
163: (8)                 Normalize inputs to two arg functions to fix type promotion rules
164: (8)                 NumPy deviates from the spec type promotion rules in cases where one
165: (8)                 argument is 0-dimensional and the other is not. For example:
166: (8)                 >>> import numpy as np
167: (8)                 >>> a = np.array([1.0], dtype=np.float32)
168: (8)                 >>> b = np.array(1.0, dtype=np.float64)
169: (8)                 >>> np.add(a, b) # The spec says this should be float64
170: (8)                             array([2.], dtype=float32)
171: (8)                 To fix this, we add a dimension to the 0-dimension array before
172: (8)                 passing it
173: (8)                 through. This works because a dimension would be added anyway from
174: (8)                 broadcasting, so the resulting shape is the same, but this prevents

```

```

169: (8)         from not promoting the dtype.
170: (8)
171: (8)
172: (12)        """
173: (8)        if x1.ndim == 0 and x2.ndim != 0:
174: (12)            x1 = Array._new(x1._array[None])
175: (8)        elif x2.ndim == 0 and x1.ndim != 0:
176: (12)            x2 = Array._new(x2._array[None])
177: (8)        return (x1, x2)
178: (4)    def _validate_index(self, key):
179: (8)        """
180: (8)        Validate an index according to the array API.
181: (8)        The array API specification only requires a subset of indices that are
182: (8)        supported by NumPy. This function will reject any index that is
183: (8)        allowed by NumPy but not required by the array API specification. We
184: (8)        always raise ``IndexError`` on such indices (the spec does not require
185: (8)        any specific behavior on them, but this makes the NumPy array API
186: (8)        namespace a minimal implementation of the spec). See
187: (8)        https://data-apis.org/array-api/latest/API\_specification/indexing.html
188: (8)        for the full list of required indexing behavior
189: (8)        This function raises IndexError if the index ``key`` is invalid. It
190: (8)        only raises ``IndexError`` on indices that are not already rejected by
191: (8)        NumPy, as NumPy will already raise the appropriate error on such
192: (8)        indices. ``shape`` may be None, in which case, only cases that are
193: (8)        independent of the array shape are checked.
194: (8)        The following cases are allowed by NumPy, but not specified by the
195: (10)       array
196: (10)       API specification:
197: (8)
198: (10)       - Indices to not include an implicit ellipsis at the end. That is,
199: (10)       every axis of an array must be explicitly indexed or an ellipsis
200: (10)       included. This behaviour is sometimes referred to as flat indexing.
201: (10)       - The start and stop of a slice may not be out of bounds. In
202: (10)       particular, for a slice ``i:j:k`` on an axis of size ``n``, only the
203: (10)       following are allowed:
204: (8)           - ``i`` or ``j`` omitted (``None``).
205: (8)           - ``-n <= i <= max(0, n - 1)``.
206: (8)           - For ``k > 0`` or ``k`` omitted (``None``), ``-n <= j <= n``.
207: (8)           - For ``k < 0``, ``-n - 1 <= j <= max(0, n - 1)``.
208: (8)       - Boolean array indices are not allowed as part of a larger tuple
209: (8)       index.
210: (8)       - Integer array indices are not allowed (with the exception of 0-D
211: (8)       arrays, which are treated the same as scalars).
212: (8)
213: (8)       Additionally, it should be noted that indices that would return a
214: (8)       scalar in NumPy will return a 0-D array. Array scalars are not allowed
215: (12)       in the specification, only 0-D arrays. This is done in the
216: (16)       ``Array._new`` constructor, not this function.

## File 27 - \_\_init\_\_.py:

```

1: (0)      """
2: (0)      A NumPy sub-namespace that conforms to the Python array API standard.
3: (0)      This submodule accompanies NEP 47, which proposes its inclusion in NumPy. It
4: (0)      is still considered experimental, and will issue a warning when imported.
5: (0)      This is a proof-of-concept namespace that wraps the corresponding NumPy
6: (0)      functions to give a conforming implementation of the Python array API standard
7: (0)      (https://data-apis.github.io/array-api/latest/). The standard is currently in
8: (0)      an RFC phase and comments on it are both welcome and encouraged. Comments
9: (0)      should be made either at https://github.com/data-apis/array-api or at
10: (0)      https://github.com/data-apis/consortium-feedback/discussions.
11: (0)      NumPy already follows the proposed spec for the most part, so this module
12: (0)      serves mostly as a thin wrapper around it. However, NumPy also implements a
13: (0)      lot of behavior that is not included in the spec, so this serves as a
14: (0)      restricted subset of the API. Only those functions that are part of the spec
15: (0)      are included in this namespace, and all functions are given with the exact
16: (0)      signature given in the spec, including the use of position-only arguments, and
17: (0)      omitting any extra keyword arguments implemented by NumPy but not part of the
18: (0)      spec. The behavior of some functions is also modified from the NumPy behavior
19: (0)      to conform to the standard. Note that the underlying array object itself is
20: (0)      wrapped in a wrapper Array() class, but is otherwise unchanged. This submodule
21: (0)      is implemented in pure Python with no C extensions.
22: (0)      The array API spec is designed as a "minimal API subset" and explicitly allows
23: (0)      libraries to include behaviors not specified by it. But users of this module
24: (0)      that intend to write portable code should be aware that only those behaviors
25: (0)      that are listed in the spec are guaranteed to be implemented across libraries.
26: (0)      Consequently, the NumPy implementation was chosen to be both conforming and
```

```

27: (0) minimal, so that users can use this implementation of the array API namespace
28: (0) and be sure that behaviors that it defines will be available in conforming
29: (0) namespaces from other libraries.
30: (0) A few notes about the current state of this submodule:
31: (0) - There is a test suite that tests modules against the array API standard at
32: (2) https://github.com/data-apis/array-api-tests. The test suite is still a work
33: (2) in progress, but the existing tests pass on this module, with a few
34: (2) exceptions:
35: (2) - DLPack support (see https://github.com/data-apis/array-api/pull/106) is
36: (4) not included here, as it requires a full implementation in NumPy proper
37: (4) first.
38: (2) The test suite is not yet complete, and even the tests that exist are not
39: (2) guaranteed to give a comprehensive coverage of the spec. Therefore, when
40: (2) reviewing and using this submodule, you should refer to the standard
41: (2) documents themselves. There are some tests in numpy.array_api.tests, but
42: (2) they primarily focus on things that are not tested by the official array API
43: (2) test suite.
44: (0) - There is a custom array object, numpy.array_api.Array, which is returned by
45: (2) all functions in this module. All functions in the array API namespace
46: (2) implicitly assume that they will only receive this object as input. The only
47: (2) way to create instances of this object is to use one of the array creation
48: (2) functions. It does not have a public constructor on the object itself. The
49: (2) object is a small wrapper class around numpy.ndarray. The main purpose of it
50: (2) is to restrict the namespace of the array object to only those dtypes and
51: (2) only those methods that are required by the spec, as well as to limit/change
52: (2) certain behavior that differs in the spec. In particular:
53: (2) - The array API namespace does not have scalar objects, only 0-D arrays.
54: (4) Operations on Array that would create a scalar in NumPy create a 0-D
55: (4) array.
56: (2) - Indexing: Only a subset of indices supported by NumPy are required by the
57: (4) spec. The Array object restricts indexing to only allow those types of
58: (4) indices that are required by the spec. See the docstring of the
59: (4) numpy.array_api.Array._validate_indices helper function for more
60: (4) information.
61: (2) - Type promotion: Some type promotion rules are different in the spec. In
62: (4) particular, the spec does not have any value-based casting. The spec also
63: (4) does not require cross-kind casting, like integer -> floating-point. Only
64: (4) those promotions that are explicitly required by the array API
65: (4) specification are allowed in this module. See NEP 47 for more info.
66: (2) - Functions do not automatically call asarray() on their input, and will not
67: (4) work if the input type is not Array. The exception is array creation
68: (4) functions, and Python operators on the Array object, which accept Python
69: (4) scalars of the same type as the array dtype.
70: (0) - All functions include type annotations, corresponding to those given in the
71: (2) spec (see _typing.py for definitions of some custom types). These do not
72: (2) currently fully pass mypy due to some limitations in mypy.
73: (0) - Dtype objects are just the NumPy dtype objects, e.g., float64 =
74: (2) np.dtype('float64'). The spec does not require any behavior on these dtype
75: (2) objects other than that they be accessible by name and be comparable by
76: (2) equality, but it was considered too much extra complexity to create custom
77: (2) objects to represent dtypes.
78: (0) - All places where the implementations in this submodule are known to deviate
79: (2) from their corresponding functions in NumPy are marked with "# Note:"
80: (2) comments.
81: (0) Still TODO in this module are:
82: (0) - DLPack support for numpy.ndarray is still in progress. See
83: (2) https://github.com/numpy/numpy/pull/19083.
84: (0) - The copy=False keyword argument to asarray() is not yet implemented. This
85: (2) requires support in numpy.asarray() first.
86: (0) - Some functions are not yet fully tested in the array API test suite, and may
87: (2) require updates that are not yet known until the tests are written.
88: (0) - The spec is still in an RFC phase and may still have minor updates, which
89: (2) will need to be reflected here.
90: (0) - Complex number support in array API spec is planned but not yet finalized,
91: (2) as are the fft extension and certain linear algebra functions such as eig
92: (2) that require complex dtypes.

88: (4)         Set printing options.
89: (4)         These options determine the way floating point numbers, arrays and
90: (4)         other NumPy objects are displayed.
91: (4)         Parameters
92: (4)         -----
93: (8)             precision : int or None, optional
94: (8)                 Number of digits of precision for floating point output (default 8).
95: (8)                 May be None if `floatmode` is not `fixed`, to print as many digits as
96: (4)                 necessary to uniquely specify the value.
97: (8)             threshold : int, optional
98: (8)                 Total number of array elements which trigger summarization
99: (8)                 rather than full repr (default 1000).
100: (4)                To always use the full repr without summarization, pass `sys.maxsize`.
101: (8)             edgeitems : int, optional
102: (8)                 Number of array items in summary at beginning and end of
103: (4)                 each dimension (default 3).
104: (8)             linewidth : int, optional
105: (8)                 The number of characters per line for the purpose of inserting
106: (4)                 line breaks (default 75).
107: (8)             suppress : bool, optional
108: (8)                 If True, always print floating point numbers using fixed point
109: (8)                 notation, in which case numbers equal to zero in the current precision
110: (8)                 will print as zero. If False, then scientific notation is used when
111: (8)                 absolute value of the smallest number is < 1e-4 or the ratio of the
112: (4)                 maximum absolute value to the minimum is > 1e3. The default is False.
113: (8)             nanstr : str, optional
114: (4)                 String representation of floating point not-a-number (default nan).
115: (8)             infstr : str, optional
116: (4)                 String representation of floating point infinity (default inf).
117: (8)             sign : string, either '-', '+', or ' ', optional
118: (8)                 Controls printing of the sign of floating-point types. If '+', always
119: (8)                 print the sign of positive values. If ' ', always prints a space
120: (8)                 (whitespace character) in the sign position of positive values. If
121: (4)                 '-', omit the sign character of positive values. (default '-')
122: (8)             formatter : dict of callables, optional
123: (8)                 If not None, the keys should indicate the type(s) that the respective
124: (8)                 formatting function applies to. Callables should return a string.
125: (8)                 Types that are not specified (by their corresponding keys) are handled
126: (8)                 by the default formatters. Individual types for which a formatter
127: (8)                 can be set are:
128: (8)                     - 'bool'
129: (8)                     - 'int'
130: (8)                     - 'timedelta' : a `numpy.timedelta64`
131: (8)                     - 'datetime' : a `numpy.datetime64`

```

```

132: (8)           - 'longfloat' : 128-bit floats
133: (8)           - 'complexfloat'
134: (8)           - 'longcomplexfloat' : composed of two 128-bit floats
135: (8)           - 'numpystr' : types `numpy.bytes_` and `numpy.str_`
136: (8)           - 'object' : `np.object_` arrays
137: (8)           Other keys that can be used to set a group of types at once are:
138: (8)           - 'all' : sets all types
139: (8)           - 'int_kind' : sets 'int'
140: (8)           - 'float_kind' : sets 'float' and 'longfloat'
141: (8)           - 'complex_kind' : sets 'complexfloat' and 'longcomplexfloat'
142: (8)           - 'str_kind' : sets 'numpystr'
143: (4)           floatmode : str, optional
144: (8)             Controls the interpretation of the `precision` option for
145: (8)             floating-point types. Can take the following values
146: (8)             (default maxprec_equal):
147: (8)               * 'fixed': Always print exactly `precision` fractional digits,
148: (16)                 even if this would print more or fewer digits than
149: (16)                 necessary to specify the value uniquely.
150: (8)               * 'unique': Print the minimum number of fractional digits necessary
151: (16)                 to represent each value uniquely. Different elements may
152: (16)                 have a different number of digits. The value of the
153: (16)                 `precision` option is ignored.
154: (8)               * 'maxprec': Print at most `precision` fractional digits, but if
155: (16)                 an element can be uniquely represented with fewer digits
156: (16)                 only print it with that many.
157: (8)               * 'maxprec_equal': Print at most `precision` fractional digits,
158: (16)                 but if every element in the array can be uniquely
159: (16)                 represented with an equal number of fewer digits, use that
160: (16)                 many digits for all elements.
161: (4)           legacy : string or `False`, optional
162: (8)             If set to the string ``1.13`` enables 1.13 legacy printing mode. This
163: (8)             approximates numpy 1.13 print output by including a space in the sign
164: (8)             position of floats and different behavior for 0d arrays. This also
165: (8)             enables 1.21 legacy printing mode (described below).
166: (8)             If set to the string ``1.21`` enables 1.21 legacy printing mode. This
167: (8)             approximates numpy 1.21 print output of complex structured dtypes
168: (8)             by not inserting spaces after commas that separate fields and after
169: (8)             colons.
170: (8)             If set to `False`, disables legacy mode.
171: (8)             Unrecognized strings will be ignored with a warning for forward
172: (8)             compatibility.
173: (8)             .. versionadded:: 1.14.0
174: (8)             .. versionchanged:: 1.22.0
175: (4)           See Also
176: (4)           -----
177: (4)             get_printoptions, printoptions, set_string_function, array2string
178: (4)           Notes
179: (4)           -----
180: (4)             `formatter` is always reset with a call to `set_printoptions`.
181: (4)             Use `printoptions` as a context manager to set the values temporarily.
182: (4)           Examples
183: (4)           -----
184: (4)             Floating point precision can be set:
185: (4)             >>> np.set_printoptions(precision=4)
186: (4)             >>> np.array([1.123456789])
187: (4)             [1.1235]
188: (4)             Long arrays can be summarised:
189: (4)             >>> np.set_printoptions(threshold=5)
190: (4)             >>> np.arange(10)
191: (4)             array([0, 1, 2, ..., 7, 8, 9])
192: (4)             Small results can be suppressed:
193: (4)             >>> eps = np.finfo(float).eps
194: (4)             >>> x = np.arange(4.)
195: (4)             >>> x**2 - (x + eps)**2
196: (4)             array([-4.9304e-32, -4.4409e-16,  0.0000e+00,  0.0000e+00])
197: (4)             >>> np.set_printoptions(suppress=True)
198: (4)             >>> x**2 - (x + eps)**2
199: (4)             array([-0., -0.,  0.,  0.])
200: (4)             A custom formatter can be used to display array elements as desired:

```

```

201: (4)          >>> np.set_printoptions(formatter={'all':lambda x: 'int: '+str(-x)})
202: (4)          >>> x = np.arange(3)
203: (4)          >>> x
204: (4)          array([int: 0, int: -1, int: -2])
205: (4)          >>> np.set_printoptions() # formatter gets reset
206: (4)          >>> x
207: (4)          array([0, 1, 2])
208: (4)          To put back the default options, you can use:
209: (4)          >>> np.set_printoptions(edgeitems=3, infstr='inf',
210: (4)          ... linewidth=75, nanstr='nan', precision=8,
211: (4)          ... suppress=False, threshold=1000, formatter=None)
212: (4)          Also to temporarily override options, use `printoptions` as a context
manager:
213: (4)          >>> with np.printoptions(precision=2, suppress=True, threshold=5):
214: (4)          ...     np.linspace(0, 10, 10)
215: (4)          array([ 0. ,  1.1,  2.2, ...,  7.78,  8.89, 10. ])
216: (4)          """
217: (4)          opt = _make_options_dict(precision, threshold, edgeitems, linewidth,
218: (29)          ...             suppress, nanstr, infstr, sign, formatter,
219: (29)          ...             floatmode, legacy)
220: (4)          opt['formatter'] = formatter
221: (4)          _format_options.update(opt)
222: (4)          if _format_options['legacy'] == 113:
223: (8)          set_legacy_print_mode(113)
224: (8)          _format_options['sign'] = '-'
225: (4)          elif _format_options['legacy'] == 121:
226: (8)          set_legacy_print_mode(121)
227: (4)          elif _format_options['legacy'] == sys.maxsize:

442: (4) """
443: (4)     Return a string representation of an array.
444: (4) Parameters
445: (4) -----
446: (4) a : ndarray
447: (8)     Input array.
448: (4) max_line_width : int, optional
449: (8)     Inserts newlines if text is longer than `max_line_width`.
450: (8)     Defaults to ``numpy.get_printoptions()['linewidth']``.
451: (4) precision : int or None, optional
452: (8)     Floating point precision.
453: (8)     Defaults to ``numpy.get_printoptions()['precision']``.
454: (4) suppress_small : bool, optional
455: (8)     Represent numbers "very close" to zero as zero; default is False.
456: (8)     Very close is defined by precision: if the precision is 8, e.g.,
457: (8)     numbers smaller (in absolute value) than 5e-9 are represented as
458: (8)     zero.
459: (8)     Defaults to ``numpy.get_printoptions()['suppress']``.
460: (4) separator : str, optional
461: (8)     Inserted between elements.
462: (4) prefix : str, optional
463: (4) suffix : str, optional
464: (8)     The length of the prefix and suffix strings are used to respectively
465: (8)     align and wrap the output. An array is typically printed as::
466: (10)       prefix + array2string(a) + suffix
467: (8)     The output is left-padded by the length of the prefix string, and
468: (8)     wrapping is forced at the column ``max_line_width - len(suffix)``.
469: (8)     It should be noted that the content of prefix and suffix strings are
470: (8)     not included in the output.
471: (4) style : _NoValue, optional
472: (8)     Has no effect, do not use.
473: (8)     .. deprecated:: 1.14.0

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

474: (4) formatter : dict of callables, optional
475: (8) If not None, the keys should indicate the type(s) that the respective
476: (8) formatting function applies to. Callables should return a string.
477: (8) Types that are not specified (by their corresponding keys) are handled
478: (8) by the default formatters. Individual types for which a formatter
479: (8) can be set are:
480: (8) - 'bool'
481: (8) - 'int'
482: (8) - 'timedelta' : a `numpy.timedelta64`
483: (8) - 'datetime' : a `numpy.datetime64`
484: (8) - 'float'
485: (8) - 'longfloat' : 128-bit floats
486: (8) - 'complexfloat'
487: (8) - 'longcomplexfloat' : composed of two 128-bit floats
488: (8) - 'void' : type `numpy.void`
489: (8) - 'numpystr' : types `numpy.bytes_` and `numpy.str_`
490: (8) Other keys that can be used to set a group of types at once are:
491: (8) - 'all' : sets all types
492: (8) - 'int_kind' : sets 'int'
493: (8) - 'float_kind' : sets 'float' and 'longfloat'
494: (8) - 'complex_kind' : sets 'complexfloat' and 'longcomplexfloat'
495: (8) - 'str_kind' : sets 'numpystr'
496: (4) threshold : int, optional
497: (8) Total number of array elements which trigger summarization
498: (8) rather than full repr.
499: (8) Defaults to ``numpy.get_printoptions()['threshold']``.
500: (4) edgeitems : int, optional
501: (8) Number of array items in summary at beginning and end of
502: (8) each dimension.
503: (8) Defaults to ``numpy.get_printoptions()['edgeitems']``.
504: (4) sign : string, either '-', '+', or ' ', optional
505: (8) Controls printing of the sign of floating-point types. If '+', always
506: (8) print the sign of positive values. If ' ', always prints a space
507: (8) (whitespace character) in the sign position of positive values. If
508: (8) '-', omit the sign character of positive values.
509: (8) Defaults to ``numpy.get_printoptions()['sign']``.
510: (4) floatmode : str, optional
511: (8) Controls the interpretation of the `precision` option for
512: (8) floating-point types.
513: (8) Defaults to ``numpy.get_printoptions()['floatmode']``.
514: (8) Can take the following values:
515: (8) - 'fixed': Always print exactly `precision` fractional digits,
516: (10) even if this would print more or fewer digits than
517: (10) necessary to specify the value uniquely.
518: (8) - 'unique': Print the minimum number of fractional digits necessary
519: (10) to represent each value uniquely. Different elements may
520: (10) have a different number of digits. The value of the
521: (10) `precision` option is ignored.
522: (8) - 'maxprec': Print at most `precision` fractional digits, but if
523: (10) an element can be uniquely represented with fewer digits
524: (10) only print it with that many.
525: (8) - 'maxprec_equal': Print at most `precision` fractional digits,
526: (10) but if every element in the array can be uniquely
527: (10) represented with an equal number of fewer digits, use that
528: (10) many digits for all elements.
529: (4) legacy : string or `False`, optional
530: (8) If set to the string ``1.13`` enables 1.13 legacy printing mode. This
531: (8) approximates numpy 1.13 print output by including a space in the sign
532: (8) position of floats and different behavior for 0d arrays. If set to
533: (8) `False`, disables legacy mode. Unrecognized strings will be ignored
534: (8) with a warning for forward compatibility.
535: (8) .. versionadded:: 1.14.0
536: (4) Returns
537: (4) -----
538: (4) array_str : str
539: (8) String representation of the array.

541: (4) -----
542: (4) TypeError

```

```

543: (8)             if a callable in `formatter` does not return a string.
544: (4)             See Also
545: (4)
546: (4)             array_str, array_repr, set_printoptions, get_printoptions
547: (4)             Notes
548: (4)
549: (4)             If a formatter is specified for a certain type, the `precision` keyword is
550: (4)             ignored for that type.
551: (4)             This is a very flexible function; `array_repr` and `array_str` are using
552: (4)             `array2string` internally so keywords with the same name should work
553: (4)             identically in all three functions.
554: (4)             Examples
555: (4)
556: (4)             >>> x = np.array([1e-16,1,2,3])
557: (4)             >>> np.array2string(x, precision=2, separator=',',
558: (4)                           ...                           suppress_small=True)
559: (4)             '[0.,1.,2.,3.]'
560: (4)             >>> x = np.arange(3.)
561: (4)             >>> np.array2string(x, formatter={'float_kind':lambda x: "% .2f" % x})
562: (4)             '[0.00 1.00 2.00]'
563: (4)             >>> x = np.arange(3)
564: (4)             >>> np.array2string(x, formatter={'int':lambda x: hex(x)})
565: (4)             '[0x0 0x1 0x2]'

831: (4) Format a floating-point scalar as a decimal string in scientific notation.
832: (4) Provides control over rounding, trimming and padding. Uses and assumes
833: (4) IEEE unbiased rounding. Uses the "Dragon4" algorithm.
834: (4) Parameters
835: (4) -----
836: (4) x : python float or numpy floating scalar
837: (8)     Value to format.
838: (4) precision : non-negative integer or None, optional
839: (8)     Maximum number of digits to print. May be None if `unique` is
840: (8)     `True`, but must be an integer if unique is `False`.
841: (4) unique : boolean, optional
842: (8)     If `True`, use a digit-generation strategy which gives the shortest
843: (8)     representation which uniquely identifies the floating-point number
from
844: (8) other values of the same type, by judicious rounding. If `precision`
845: (8) is given fewer digits than necessary can be printed. If `min_digits`
846: (8) is given more can be printed, in which cases the last digit is rounded
847: (8) with unbiased rounding.
848: (8) If `False`, digits are generated as if printing an infinite-precision
849: (8) value and stopping after `precision` digits, rounding the remaining
850: (8) value with unbiased rounding
851: (4) trim : one of 'k', '.', '0', '-', optional
852: (8)     Controls post-processing trimming of trailing digits, as follows:
853: (8)     * 'k' : keep trailing zeros, keep decimal point (no trimming)
854: (8)     * '.' : trim all trailing zeros, leave decimal point
855: (8)     * '0' : trim all but the zero before the decimal point. Insert the
856: (10)      zero if it is missing.
857: (8)     * '-' : trim trailing zeros and any trailing decimal point
858: (4) sign : boolean, optional
859: (8)     Whether to show the sign for positive values.
860: (4) pad_left : non-negative integer, optional
861: (8)     Pad the left side of the string with whitespace until at least that
862: (8)     many characters are to the left of the decimal point.
863: (4) exp_digits : non-negative integer, optional
864: (8)     Pad the exponent with zeros until it contains at least this many
digits.
865: (8)     If omitted, the exponent will be at least 2 digits.
866: (4) min_digits : non-negative integer or None, optional
867: (8)     Minimum number of digits to print. This only has an effect for
868: (8)     `unique=True`. In that case more digits than necessary to uniquely
869: (8)     identify the value may be printed and rounded unbiased.

1307: (0)             def set_string_function(f, repr=True):
1308: (4)                 """
1309: (4)                 Set a Python function to be used when pretty printing arrays.
1310: (4)             Parameters
1311: (4)             -----
1312: (4)                 f : function or None
1313: (8)                 Function to be used to pretty print arrays. The function should expect
1314: (8)                 a single array argument and return a string of the representation of
1315: (8)                 the array. If None, the function is reset to the default NumPy
function
1316: (8)                 to print arrays.
1317: (4)             repr : bool, optional
1318: (8)                 If True (default), the function for pretty printing (`__repr__`)
1319: (8)                 is set, if False the function that returns the default string
1320: (8)                 representation (`__str__`) is set.
1321: (4)             See Also
1322: (4)             -----
1323: (4)                 set_printoptions, get_printoptions
1324: (4)             Examples
1325: (4)             -----
1326: (4)                 >>> def pprint(arr):
1327: (4)                     ...     return 'HA! - What are you going to do now?'
1328: (4)                     ...
1329: (4)                 >>> np.set_string_function(pprint)
1330: (4)                 >>> a = np.arange(10)
1331: (4)                 >>> a
1332: (4)                 HA! - What are you going to do now?
1333: (4)                 >>> _ = a
1334: (4)                 >>> # [0 1 2 3 4 5 6 7 8 9]
1335: (4)                 We can reset the function to the default:
1336: (4)                 >>> np.set_string_function(None)
1337: (4)                 >>> a
1338: (4)                 array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
`repr` affects either pretty printing or normal string representation.
1339: (4)                 Note that `__repr__` is still affected by setting `__str__`
1340: (4)                 because the width of each array element in the returned string becomes
1341: (4)                 equal to the length of the result of `__str__()` .
1342: (4)                 >>> x = np.arange(4)
1343: (4)                 >>> np.set_string_function(lambda x:'random', repr=False)
1344: (4)                 >>> x.__str__()
1345: (4)                 'random'
1346: (4)                 >>> x.__repr__()
1347: (4)                 'array([0, 1, 2, 3])'
1348: (4)                 """

1440: (0)          @set_module('numpy')
1441: (4)          class chararray(ndarray):
1442: (4)          """
1443: (14)          chararray(shape, itemsize=1, unicode=False, buffer=None, offset=0,
1444: (4)                      strides=None, order=None)
1445: (4)          Provides a convenient view on arrays of string and unicode values.
1446: (4)          .. note::
1447: (7)          The `chararray` class exists for backwards compatibility with
1448: (7)          Numarray, it is not recommended for new development. Starting from
1449: (7)          1.4, if one needs arrays of strings, it is recommended to use arrays of
1450: (7)          `dtype` `object_`, `bytes_` or `str_`, and use the free functions
1451: (4)          in the `numpy.char` module for fast vectorized string operations.
1452: (4)          Versus a regular NumPy array of type `str` or `unicode`, this
1453: (6)          class adds the following functionality:
1454: (9)          1) values automatically have whitespace removed from the end
1455: (6)          when indexed
1456: (9)          2) comparison operators automatically remove whitespace from the
1457: (6)          end when comparing values
1458: (9)          3) vectorized string operations are provided as methods
1459: (4)          (e.g. `endswith`) and infix operators (e.g. `"+", "*", "%"`)
1460: (4)          chararrays should be created using `numpy.char.array` or
1461: (4)          `numpy.char.asarray`, rather than this constructor directly.
1462: (4)          This constructor creates the array, using `buffer` (with `offset`
1463: (4)          and `strides`) if it is not ``None``. If `buffer` is ``None``, then
1464: (4)          constructs a new array with `strides` in "C order", unless both
1465: (4)          ``len(shape) >= 2`` and ``order='F'``, in which case `strides`
1466: (4)          is in "Fortran order".
1467: (4)          Methods
1468: (4)          -----
1469: (4)          astype
1470: (4)          argsort

2076: (4)             Create a `chararray`.
2077: (4)             .. note::
2078: (7)                 This class is provided for numarray backward-compatibility.
2079: (7)                 New code (not concerned with numarray compatibility) should use
2080: (7)                 arrays of type `bytes_` or `str_` and use the free functions
2081: (7)                 in :mod:`numpy.char <numpy.core.defchararray>` for fast
2082: (7)                 vectorized string operations instead.
2083: (4)                 Versus a regular NumPy array of type `str` or `unicode`, this
2084: (4)                 class adds the following functionality:
2085: (6)                     1) values automatically have whitespace removed from the end
2086: (9)                         when indexed
2087: (6)                     2) comparison operators automatically remove whitespace from the
2088: (9)                         end when comparing values
2089: (6)                     3) vectorized string operations are provided as methods
2090: (9)                         (e.g. `str.endswith`) and infix operators (e.g. ``+``, `*`, `%``)
2091: (4)             Parameters
2092: (4)
2093: (4)             -----
2094: (4)             obj : array of str or unicode-like
itemsize : int, optional
2095: (8)                 `itemsize` is the number of characters per scalar in the
2096: (8)                 resulting array. If `itemsize` is None, and `obj` is an
2097: (8)                 object array or a Python list, the `itemsize` will be
2098: (8)                 automatically determined. If `itemsize` is provided and `obj`
2099: (8)                 is of type str or unicode, then the `obj` string will be
2100: (8)                 chunked into `itemsize` pieces.
2101: (4)             copy : bool, optional
2102: (8)                 If true (default), then the object is copied. Otherwise, a copy
2103: (8)                 will only be made if __array__ returns a copy, if obj is a
2104: (8)                 nested sequence, or if a copy is needed to satisfy any of the other
2105: (8)                 requirements (`itemsize`, unicode, `order`, etc.).
2106: (4)             unicode : bool, optional
2107: (8)                 When true, the resulting `chararray` can contain Unicode

```

```

2108: (8)           characters, when false only 8-bit characters. If unicode is
2109: (8)           None and `obj` is one of the following:
2110: (10)          - a `chararray`,
2111: (10)          - an ndarray of type `str` or `unicode`
2112: (10)          - a Python str or unicode object,
2113: (8)          then the unicode setting of the output array will be
2114: (8)          automatically determined.
2115: (4)          order : {'C', 'F', 'A'}, optional
2116: (8)          Specify the order of the array. If order is 'C' (default), then the
2117: (8)          array will be in C-contiguous order (last-index varies the
2118: (8)          fastest). If order is 'F', then the returned array
2119: (8)          will be in Fortran-contiguous order (first-index varies the
2120: (8)          fastest). If order is 'A', then the returned array may
2121: (8)          be in any order (either C-, Fortran-contiguous, or even
2122: (8)          discontiguous).

```

2177: (4)             necessary.
2178: (4)             Versus a regular NumPy array of type `str` or `unicode`, this
2179: (4)             class adds the following functionality:
2180: (6)               1) values automatically have whitespace removed from the end
2181: (9)                 when indexed
2182: (6)               2) comparison operators automatically remove whitespace from the
2183: (9)                 end when comparing values
2184: (6)               3) vectorized string operations are provided as methods
2185: (9)                 (e.g. `str.endswith`) and infix operators (e.g. ``+``, ``*``, ``%``)
2186: (4)             Parameters
2187: (4)             -----
2188: (4)             obj : array of str or unicode-like
2189: (4)             itemsize : int, optional
2190: (8)               `itemsize` is the number of characters per scalar in the
2191: (8)               resulting array. If `itemsize` is None, and `obj` is an
2192: (8)               object array or a Python list, the `itemsize` will be
2193: (8)               automatically determined. If `itemsize` is provided and `obj`
2194: (8)               is of type str or unicode, then the `obj` string will be
2195: (8)               chunked into `itemsize` pieces.
2196: (4)             unicode : bool, optional
2197: (8)               When true, the resulting `chararray` can contain Unicode
2198: (8)               characters, when false only 8-bit characters. If unicode is
2199: (8)               None and `obj` is one of the following:
2200: (10)              - a `chararray`,
2201: (10)              - an ndarray of type `str` or `unicode`
2202: (10)              - a Python str or unicode object,
2203: (8)               then the unicode setting of the output array will be
2204: (8)               automatically determined.
2205: (4)             order : {'C', 'F'}, optional
2206: (8)               Specify the order of the array. If order is 'C' (default), then the
2207: (8)               array will be in C-contiguous order (last-index varies the
2208: (8)               fastest). If order is 'F', then the returned array
2209: (8)               will be in Fortran-contiguous order (first-index varies the
2210: (8)               fastest).
2211: (4)             """
2212: (4)             return array(obj, itemsize, copy=False,
2213: (17)                           unicode=unicode, order=order)

```

726: (4)             Evaluates the Einstein summation convention on the operands.
727: (4)             Using the Einstein summation convention, many common multi-dimensional,
728: (4)             linear algebraic array operations can be represented in a simple fashion.
729: (4)             In *implicit* mode `einsum` computes these values.
730: (4)             In *explicit* mode, `einsum` provides further flexibility to compute
731: (4)             other array operations that might not be considered classical Einstein
732: (4)             summation operations, by disabling, or forcing summation over specified
733: (4)             subscript labels.
734: (4)             See the notes and examples for clarification.
735: (4)             Parameters
736: (4)             -----
737: (4)             subscripts : str
738: (4)               Specifies the subscripts for summation as comma separated list of
739: (8)               subscript labels. An implicit (classical Einstein summation)
740: (8)               calculation is performed unless the explicit indicator '->' is
741: (8)               included as well as subscript labels of the precise output form.
742: (8)             operands : list of array_like
743: (4)               These are the arrays for the operation.
744: (8)             out : ndarray, optional
745: (4)               If provided, the calculation is done into this array.
746: (8)             dtype : {data-type, None}, optional
747: (4)               If provided, forces the calculation to use the data type specified.
748: (8)               Note that you may have to also give a more liberal `casting`
749: (8)               parameter to allow the conversions. Default is None.
750: (8)             order : {'C', 'F', 'A', 'K'}, optional
751: (4)               Controls the memory layout of the output. 'C' means it should
752: (8)               be C contiguous. 'F' means it should be Fortran contiguous,
753: (8)               'A' means it should be 'F' if the inputs are all 'F', 'C' otherwise.
754: (8)               'K' means it should be as close to the layout as the inputs as
755: (8)               is possible, including arbitrarily permuted axes.
756: (8)               Default is 'K'.
757: (8)

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

758: (4) casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
759: (8)     Controls what kind of data casting may occur. Setting this to
760: (8)     'unsafe' is not recommended, as it can adversely affect accumulations.
761: (10)    * 'no' means the data types should not be cast at all.
762: (10)    * 'equiv' means only byte-order changes are allowed.
763: (10)    * 'safe' means only casts which can preserve values are allowed.
764: (10)    * 'same_kind' means only safe casts or casts within a kind,
765: (12)        like float64 to float32, are allowed.
766: (10)    * 'unsafe' means any data conversions may be done.
767: (8)        Default is 'safe'.
768: (4) optimize : {False, True, 'greedy', 'optimal'}, optional
769: (8)     Controls if intermediate optimization should occur. No optimization
770: (8)     will occur if False and True will default to the 'greedy' algorithm.
771: (8)     Also accepts an explicit contraction list from the ``np.einsum_path``
772: (8)     function. See ``np.einsum_path`` for more details. Defaults to False.
773: (4) Returns
774: (4) -----
775: (4) output : ndarray
776: (8)     The calculation based on the Einstein summation convention.
777: (4) See Also
778: (4) -----
779: (4) einsum_path, dot, inner, outer, tensordot, linalg.multi_dot
780: (4) einops :
781: (8)     similar verbose interface is provided by
782: (8)     `einops <https://github.com/arogozhnikov/einops>`_ package to cover
783: (8)     additional operations: transpose, reshape/flatten, repeat/tile,
784: (8)     squeeze/unsqueeze and reductions.
785: (4) opt_einsum :
786: (8)     `opt_einsum <https://optimized-einsum.readthedocs.io/en/stable/>`_
787: (8)     optimizes contraction order for einsum-like expressions
788: (8)     in backend-agnostic manner.
789: (4) Notes
790: (4) -----
791: (4) .. versionadded:: 1.6.0
792: (4) The Einstein summation convention can be used to compute
793: (4) many multi-dimensional, linear algebraic array operations. `einsum`
794: (4) provides a succinct way of representing these.
795: (4) A non-exhaustive list of these operations,
796: (4) which can be computed by `einsum`, is shown below along with examples:
797: (4) * Trace of an array, :py:func:`numpy.trace`.
798: (4) * Return a diagonal, :py:func:`numpy.diag`.
799: (4) * Array axis summations, :py:func:`numpy.sum`.
800: (4) * Transpositions and permutations, :py:func:`numpy.transpose`.
801: (4) * Matrix multiplication and dot product, :py:func:`numpy.matmul`  

:py:func:`numpy.dot`.
802: (4) * Vector inner and outer products, :py:func:`numpy.inner`  

:py:func:`numpy.outer`.
803: (4) * Broadcasting, element-wise and scalar multiplication,
:py:func:`numpy.multiply`.
804: (4) * Tensor contractions, :py:func:`numpy.tensordot`.
805: (4) * Chained array operations, in efficient calculation order,  

:py:func:`numpy.einsum_path`.
806: (4) The subscripts string is a comma-separated list of subscript labels,
807: (4) where each label refers to a dimension of the corresponding operand.
808: (4) Whenever a label is repeated it is summed, so ``np.einsum('i,i', a, b)``
809: (4) is equivalent to :py:func:`np.inner(a,b) <numpy.inner>`. If a label
810: (4) appears only once, it is not summed, so ``np.einsum('i', a)`` produces a
811: (4) view of ``a`` with no changes. A further example ``np.einsum('ij,jk', a,
b)``
812: (4) describes traditional matrix multiplication and is equivalent to
813: (4) :py:func:`np.matmul(a,b) <numpy.matmul>`. Repeated subscript labels in one
814: (4) operand take the diagonal. For example, ``np.einsum('ii', a)`` is
equivalent
815: (4) to :py:func:`np.trace(a) <numpy.trace>`.
816: (4) In *implicit mode*, the chosen subscripts are important
817: (4) since the axes of the output are reordered alphabetically. This
818: (4) means that ``np.einsum('ij', a)`` doesn't affect a 2D array, while
819: (4) ``np.einsum('ji', a)`` takes its transpose. Additionally,
820: (4) ``np.einsum('ij,jk', a, b)`` returns a matrix multiplication, while,
```

```

821: (4) ``np.einsum('ij,jh', a, b)`` returns the transpose of the
822: (4) multiplication since subscript 'h' precedes subscript 'i'.
823: (4) In *explicit mode* the output can be directly controlled by
824: (4) specifying output subscript labels. This requires the
825: (4) identifier ' $\rightarrow$ ' as well as the list of output subscript labels.
826: (4) This feature increases the flexibility of the function since
827: (4) summing can be disabled or forced when required. The call
828: (4) ``np.einsum('i $\rightarrow$ ', a)`` is like :py:func:`np.sum(a, axis=-1) <numpy.sum>`,
829: (4) and ``np.einsum('ii $\rightarrow$ i', a)`` is like :py:func:`np.diag(a) <numpy.diag>`.
830: (4) The difference is that `einsum` does not allow broadcasting by default.
831: (4) Additionally ``np.einsum('ij,jh $\rightarrow$ ih', a, b)`` directly specifies the
832: (4) order of the output subscript labels and therefore returns matrix
833: (4) multiplication, unlike the example above in implicit mode.
834: (4) To enable and control broadcasting, use an ellipsis. Default
835: (4) NumPy-style broadcasting is done by adding an ellipsis
836: (4) to the left of each term, like ``np.einsum('...ii $\rightarrow$ ...i', a)``.
837: (4) To take the trace along the first and last axes,
838: (4) you can do ``np.einsum('i...i', a)``, or to do a matrix-matrix
839: (4) product with the left-most indices instead of rightmost, one can do
840: (4) ``np.einsum('ij...,jk... $\rightarrow$ ik...', a, b)``.
841: (4) When there is only one operand, no axes are summed, and no output
842: (4) parameter is provided, a view into the operand is returned instead
843: (4) of a new array. Thus, taking the diagonal as ``np.einsum('ii $\rightarrow$ i', a)``
844: (4) produces a view (changed in version 1.10.0).
845: (4) `einsum` also provides an alternative way to provide the subscripts
846: (4) and operands as ``einsum(op0, sublist0, op1, sublist1, ...,
[sublistout])``.
847: (4) If the output shape is not provided in this format `einsum` will be
848: (4) calculated in implicit mode, otherwise it will be performed explicitly.
849: (4) The examples below have corresponding `einsum` calls with the two
850: (4) parameter methods.
851: (4) .. versionadded:: 1.10.0
852: (4) Views returned from einsum are now writeable whenever the input array
853: (4) is writeable. For example, ``np.einsum('ijk... $\rightarrow$ kji...', a)`` will now
854: (4) have the same effect as :py:func:`np.swapaxes(a, 0, 2) <numpy.swapaxes>`-
855: (4) and ``np.einsum('ii $\rightarrow$ i', a)`` will return a writeable view of the diagonal
856: (4) of a 2D array.
857: (4) .. versionadded:: 1.12.0
858: (4) Added the ``optimize`` argument which will optimize the contraction order
859: (4) of an einsum expression. For a contraction with three or more operands
this
860: (4) can greatly increase the computational efficiency at the cost of a larger
861: (4) memory footprint during computation.
862: (4) Typically a 'greedy' algorithm is applied which empirical tests have shown
863: (4) returns the optimal path in the majority of cases. In some cases 'optimal'
864: (4) will return the superlative path through a more expensive, exhaustive
search.
865: (4) For iterative calculations it may be advisable to calculate the optimal
path
866: (4) once and reuse that path by supplying it as an argument. An example is
given
867: (4) below.
868: (4) See :py:func:`numpy.einsum_path` for more details.
869: (4) Examples
870: (4) -----
871: (4) >>> a = np.arange(25).reshape(5,5)
872: (4) >>> b = np.arange(5)
873: (4) >>> c = np.arange(6).reshape(2,3)
874: (4) Trace of a matrix:
875: (4) >>> np.einsum('ii', a)
876: (4) 60
877: (4) >>> np.einsum(a, [0,0])
878: (4) 60
879: (4) >>> np.trace(a)
880: (4) 60
881: (4) Extract the diagonal (requires explicit form):
882: (4) >>> np.einsum('ii $\rightarrow$ i', a)
883: (4) array([ 0,  6, 12, 18, 24])
884: (4) >>> np.einsum(a, [0,0], [0])

```

```

885: (4) array([ 0,  6, 12, 18, 24])
886: (4) >>> np.diag(a)
887: (4) array([ 0,  6, 12, 18, 24])
888: (4) Sum over an axis (requires explicit form):
889: (4) >>> np.einsum('ij->i', a)
890: (4) array([ 10, 35, 60, 85, 110])
891: (4) >>> np.einsum(a, [0,1], [0])
892: (4) array([ 10, 35, 60, 85, 110])
893: (4) >>> np.sum(a, axis=1)
894: (4) array([ 10, 35, 60, 85, 110])
895: (4) For higher dimensional arrays summing a single axis can be done with
ellipsis:
896: (4) >>> np.einsum('...j->...', a)
897: (4) array([ 10, 35, 60, 85, 110])
898: (4) >>> np.einsum(a, [Ellipsis,1], [Ellipsis])
899: (4) array([ 10, 35, 60, 85, 110])
900: (4) Compute a matrix transpose, or reorder any number of axes:
901: (4) >>> np.einsum('ji', c)
902: (4) array([[0, 3],
903: (11)     [1, 4],
904: (11)     [2, 5]])
905: (4) >>> np.einsum('ij->ji', c)
906: (4) array([[0, 3],
907: (11)     [1, 4],
908: (11)     [2, 5]])
909: (4) >>> np.einsum(c, [1,0])
910: (4) array([[0, 3],
911: (11)     [1, 4],
912: (11)     [2, 5]])
913: (4) >>> np.transpose(c)
914: (4) array([[0, 3],
915: (11)     [1, 4],
916: (11)     [2, 5]])
917: (4) Vector inner products:
918: (4) >>> np.einsum('i,i', b, b)
919: (4) 30
920: (4) >>> np.einsum(b, [0], b, [0])
921: (4) 30
922: (4) >>> np.inner(b,b)
923: (4) 30
924: (4) Matrix vector multiplication:
925: (4) >>> np.einsum('ij,j', a, b)
926: (4) array([ 30, 80, 130, 180, 230])
927: (4) >>> np.einsum(a, [0,1], b, [1])
928: (4) array([ 30, 80, 130, 180, 230])
929: (4) >>> np.dot(a, b)
930: (4) array([ 30, 80, 130, 180, 230])
931: (4) >>> np.einsum('...j,j', a, b)
932: (4) array([ 30, 80, 130, 180, 230])
933: (4) Broadcasting and scalar multiplication:
934: (4) >>> np.einsum('..., ...', 3, c)
935: (4) array([[ 0,  3,  6],
936: (11)     [ 9, 12, 15]])
937: (4) >>> np.einsum(',ij', 3, c)
938: (4) array([[ 0,  3,  6],
939: (11)     [ 9, 12, 15]])
940: (4) >>> np.einsum(3, [Ellipsis], c, [Ellipsis])
941: (4) array([[ 0,  3,  6],
942: (11)     [ 9, 12, 15]])
943: (4) >>> np.multiply(3, c)

974: (11)           [4664., 5018.],
975: (11)           [4796., 5162.],
976: (11)           [4928., 5306.]])
977: (4)          Writeable returned arrays (since version 1.10.0):
978: (4)          >>> a = np.zeros((3, 3))
979: (4)          >>> np.einsum('ii->i', a)[:] = 1
980: (4)          >>> a
981: (4)          array([[1., 0., 0.],
982: (11)           [0., 1., 0.],
983: (11)           [0., 0., 1.]])
984: (4)          Example of ellipsis use:
985: (4)          >>> a = np.arange(6).reshape((3,2))
986: (4)          >>> b = np.arange(12).reshape((4,3))
987: (4)          >>> np.einsum('ki,jk->ij', a, b)
988: (4)          array([[10, 28, 46, 64],
989: (11)           [13, 40, 67, 94]])
990: (4)          >>> np.einsum('ki,...k->i...', a, b)
991: (4)          array([[10, 28, 46, 64],
992: (11)           [13, 40, 67, 94]])
993: (4)          >>> np.einsum('k...,jk', a, b)
994: (4)          array([[10, 28, 46, 64],
995: (11)           [13, 40, 67, 94]])
996: (4)          Chained array operations. For more complicated contractions, speed ups
997: (4)          might be achieved by repeatedly computing a 'greedy' path or pre-computing
the
998: (4)          'optimal' path and repeatedly applying it, using an
999: (4)          `einsum_path` insertion (since version 1.12.0). Performance improvements
can be
1000: (4)          particularly significant with larger arrays:
1001: (4)          >>> a = np.ones(64).reshape(2,4,8)
1002: (4)          Basic `einsum`: ~1520ms (benchmarked on 3.1GHz Intel i5.)
1003: (4)          >>> for iteration in range(500):
1004: (4)              ...      _ = np.einsum('ijk,ilm,njm,nlk,abc->',a,a,a,a,a,a)
1005: (4)          Sub-optimal `einsum` (due to repeated path calculation time): ~330ms
1006: (4)          >>> for iteration in range(500):
1007: (4)              ...      _ = np.einsum('ijk,ilm,njm,nlk,abc->',a,a,a,a,a,a,
optimize='optimal')
1008: (4)          Greedy `einsum` (faster optimal path approximation): ~160ms
1009: (4)          >>> for iteration in range(500):
1010: (4)              ...      _ = np.einsum('ijk,ilm,njm,nlk,abc->',a,a,a,a,a,a,
optimize='greedy')
1011: (4)          Optimal `einsum` (best usage pattern in some use cases): ~110ms
1012: (4)          >>> path = np.einsum_path('ijk,ilm,njm,nlk,abc->',a,a,a,a,a,a,
optimize='optimal')[0]
1013: (4)          >>> for iteration in range(500):
1014: (4)              ...      _ = np.einsum('ijk,ilm,njm,nlk,abc->',a,a,a,a,a,a, optimize=path)

    return (a, out)
@array_function_dispatch(_take_dispatcher)
def take(a, indices, axis=None, out=None, mode='raise'):
    """
    Take elements from an array along an axis.
    When axis is not None, this function does the same thing as "fancy"
    indexing (indexing arrays using arrays); however, it can be easier to use
    if you need elements along a given axis. A call such as
    ``np.take(arr, indices, axis=3)`` is equivalent to
    ``arr[:, :, :, indices, ...]``.
    Explained without fancy indexing, this is equivalent to the following use
    of `ndindex`, which sets each of ``ii``, ``jj``, and ``kk`` to a tuple of
    indices::
        Ni, Nk = a.shape[:axis], a.shape[axis+1:]
        Nj = indices.shape
        for ii in ndindex(Ni):
            for jj in ndindex(Nj):
                for kk in ndindex(Nk):
                    out[ii + jj + kk] = a[ii + (indices[jj],) + kk]
    Parameters
    -----

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

84: (4)     a : array_like (Ni..., M, Nk...)
85: (8)       The source array.
86: (4)     indices : array_like (Nj...)
87: (8)       The indices of the values to extract.
88: (8)       .. versionadded:: 1.8.0
89: (8)       Also allow scalars for indices.
90: (4)     axis : int, optional
91: (8)       The axis over which to select values. By default, the flattened
92: (8)       input array is used.
93: (4)     out : ndarray, optional (Ni..., Nj..., Nk...)
94: (8)       If provided, the result will be placed in this array. It should
95: (8)       be of the appropriate shape and dtype. Note that `out` is always
96: (8)       buffered if `mode='raise'`; use other modes for better performance.
97: (4)     mode : {'raise', 'wrap', 'clip'}, optional
98: (8)       Specifies how out-of-bounds indices will behave.
99: (8)       * 'raise' -- raise an error (default)
100: (8)      * 'wrap' -- wrap around
101: (8)      * 'clip' -- clip to the range
102: (8)       'clip' mode means that all indices that are too large are replaced
103: (8)       by the index that addresses the last element along that axis. Note
104: (8)       that this disables indexing with negative numbers.
105: (4)   Returns
106: (4)   -----
107: (4)   out : ndarray (Ni..., Nj..., Nk...)
108: (8)       The returned array has the same type as `a`.
109: (4)   See Also
110: (4)   -----
111: (4)   compress : Take elements using a boolean mask
112: (4)   ndarray.take : equivalent method
113: (4)   take_along_axis : Take elements by matching the array and the index arrays
114: (4)
115: (4)
116: (4)   Notes
117: (4)   -----
118: (4)   By eliminating the inner loop in the description above, and using `s_` to
119: (8)   build simple slice objects, `take` can be expressed in terms of applying
120: (8)   fancy indexing to each 1-d slice:::
121: (12)  Ni, Nk = a.shape[:axis], a.shape[axis+1:]
122: (16)  for ii in ndindex(Ni):
123: (4)    for kk in ndindex(Nj):
124: (8)      out[ii + s_[...,] + kk] = a[ii + s_[:,] + kk][indices]
125: (4)   For this reason, it is equivalent to (but faster than) the following use
126: (4)   of `apply_along_axis`::
127: (4)   Examples
128: (4)   -----
129: (4)   >>> a = [4, 3, 5, 7, 6, 8]
130: (4)   >>> indices = [0, 1, 4]
131: (4)   >>> np.take(a, indices)
132: (4)   array([4, 3, 6])
133: (4)   In this example if `a` is an ndarray, "fancy" indexing can be used.
134: (4)   >>> a = np.array(a)
135: (4)   >>> a[indices]
136: (4)   array([4, 3, 6])
137: (4)   If `indices` is not one dimensional, the output also has these dimensions.
138: (4)   >>> np.take(a, [[0, 1], [2, 3]])
139: (11)  array([[4, 3],
140: (4)           [5, 7]])
141: (4)   """
142: (0)   return _wrapfunc(a, 'take', indices, axis=axis, out=out, mode=mode)
143: (4) def _reshape_dispatcher(a, newshape, order=None):
144: (0)   return (a,)
145: (0) @array_function_dispatch(_reshape_dispatcher)
146: (4) def reshape(a, newshape, order='C'):
147: (4)   """
148: (4)   Gives a new shape to an array without changing its data.
149: (4)   Parameters
150: (4)   -----
151: (8)   a : array_like
152: (4)       Array to be reshaped.

```

newshape : int or tuple of ints

```

153: (8)           The new shape should be compatible with the original shape. If
154: (8)           an integer, then the result will be a 1-D array of that length.
155: (8)           One shape dimension can be -1. In this case, the value is
156: (8)           inferred from the length of the array and remaining dimensions.
157: (4)           order : {'C', 'F', 'A'}, optional
158: (8)           Read the elements of `a` using this index order, and place the
159: (8)           elements into the reshaped array using this index order. 'C'
160: (8)           means to read / write the elements using C-like index order,
161: (8)           with the last axis index changing fastest, back to the first
162: (8)           axis index changing slowest. 'F' means to read / write the
163: (8)           elements using Fortran-like index order, with the first index
164: (8)           changing fastest, and the last index changing slowest. Note that
165: (8)           the 'C' and 'F' options take no account of the memory layout of
166: (8)           the underlying array, and only refer to the order of indexing.
167: (8)           'A' means to read / write the elements in Fortran-like index
168: (8)           order if `a` is Fortran *contiguous* in memory, C-like order
169: (8)           otherwise.

170: (4)           Returns
171: (4)
172: (4)           -----
173: (8)           reshaped_array : ndarray
174: (8)           This will be a new view object if possible; otherwise, it will
175: (8)           be a copy. Note there is no guarantee of the *memory layout* (C- or
176: (8)           Fortran- contiguous) of the returned array.

177: (4)           See Also
178: (4)           -----
179: (4)           ndarray.reshape : Equivalent method.

180: (4)           Notes
181: (4)           -----
182: (4)           It is not always possible to change the shape of an array without copying
183: (4)           the data.
184: (4)           The `order` keyword gives the index ordering both for *fetching* the
185: (4)           values
186: (4)           from `a`, and then *placing* the values into the output array.
187: (4)           For example, let's say you have an array:
188: (4)           >>> a = np.arange(6).reshape((3, 2))
189: (4)           >>> a
190: (11)          array([[0, 1],
191: (4)           [2, 3],
192: (4)           [4, 5]])
193: (4)           You can think of reshaping as first raveling the array (using the given
194: (4)           index order), then inserting the elements from the raveled array into the
195: (4)           new array using the same kind of index ordering as was used for the
196: (4)           raveling.
197: (4)           >>> np.reshape(a, (2, 3)) # C-like index ordering
198: (4)           array([[0, 1, 2],
199: (4)           [3, 4, 5]])
200: (11)          >>> np.reshape(np.ravel(a), (2, 3)) # equivalent to C ravel then C reshape
201: (4)           array([[0, 1, 2],
202: (4)           [3, 4, 5]])
203: (11)          >>> np.reshape(a, (2, 3), order='F') # Fortran-like index ordering
204: (4)           array([[0, 4, 3],
205: (4)           [2, 1, 5]])
206: (11)          >>> np.reshape(np.ravel(a, order='F'), (2, 3), order='F')
207: (4)           array([[0, 4, 3],
208: (4)           [2, 1, 5]])
209: (4)           Examples
210: (4)
211: (4)           >>> a = np.array([[1,2,3], [4,5,6]])
212: (4)           >>> np.reshape(a, 6)
213: (4)           array([1, 2, 3, 4, 5, 6])
214: (4)           >>> np.reshape(a, 6, order='F')
215: (4)           array([1, 4, 2, 5, 3, 6])
216: (4)           >>> np.reshape(a, (3,-1))      # the unspecified value is inferred to be
217: (4)           array([[1, 2],
218: (4)           [3, 4],
219: (4)           [5, 6]])
219: (4)           """
219: (4)           return _wrapfunc(a, 'reshape', newshape, order=order)

```

```

220: (0)
221: (4)     def _choose_dispatcher(a, choices, out=None, mode=None):
222: (4)         yield a
223: (4)         yield from choices
224: (4)         yield out
225: (0)     @array_function_dispatch(_choose_dispatcher)
226: (4)     def choose(a, choices, out=None, mode='raise'):
227: (4)         """
228: (4)             Construct an array from an index array and a list of arrays to choose
229: (4)             from.
230: (4)             First of all, if confused or uncertain, definitely look at the Examples -
231: (4)             in its full generality, this function is less simple than it might
232: (4)             seem from the following code description (below ndi =
233: (4)             `numpy.lib.index_tricks`):
234: (4)             ``np.choose(a,c) == np.array([c[a[I]][I] for I in
235: (4)             ndi.ndindex(a.shape)])``.
236: (4)             But this omits some subtleties. Here is a fully general summary:
237: (4)             Given an "index" array (`a`) of integers and a sequence of ``n`` arrays
238: (4)             (`choices`), `a` and each choice array are first broadcast, as necessary,
239: (4)             to arrays of a common shape; calling these *Ba* and *Bchoices[i], i =
240: (4)             0,...,n-1* we have that, necessarily, ``Ba.shape == Bchoices[i].shape``
241: (4)             for each ``i``. Then, a new array with shape ``Ba.shape`` is created as
242: (4)             follows:
243: (4)             * if ``mode='raise'`` (the default), then, first of all, each element of
244: (4)             ``a`` (and thus ``Ba``) must be in the range ``[0, n-1]``; now, suppose
245: (4)             that ``i`` (in that range) is the value at the ``(j0, j1, ..., jm)``
246: (4)             position in ``Ba`` - then the value at the same position
247: (4)             is the value in ``Bchoices[i]`` at that same position;
248: (4)             * if ``mode='wrap'``, values in `a` (and thus `Ba`) may be any (signed)
249: (4)             integer; modular arithmetic is used to map integers outside the range
250: (4)             `[0, n-1]` back into that range; and then the new array is constructed
251: (4)             as above;
252: (4)             * if ``mode='clip'``, values in `a` (and thus `Ba`) may be any (signed)
253: (4)             integer; negative integers are mapped to 0; values greater than ``n-1``
254: (4)             are mapped to ``n-1``; and then the new array is constructed as above.
255: (4)             Parameters
256: (4)             -----
257: (4)             a : int array
258: (4)                 This array must contain integers in ``[0, n-1]``, where ``n`` is the
259: (4)                 number of choices, unless ``mode=wrap`` or ``mode=clip``, in which
260: (4)                 cases any integers are permissible.
261: (4)             choices : sequence of arrays
262: (4)                 Choice arrays. `a` and all of the choices must be broadcastable to the
263: (4)                 same shape. If `choices` is itself an array (not recommended), then
264: (4)                 its outermost dimension (i.e., the one corresponding to
265: (4)                 ``choices.shape[0]``) is taken as defining the "sequence".
266: (4)             out : array, optional
267: (4)                 If provided, the result will be inserted into this array. It should
268: (4)                 be of the appropriate shape and dtype. Note that `out` is always
269: (4)                 buffered if ``mode='raise'``; use other modes for better performance.
270: (4)             mode : {'raise' (default), 'wrap', 'clip'}, optional
271: (4)                 Specifies how indices outside ``[0, n-1]`` will be treated:
272: (4)                     * 'raise' : an exception is raised
273: (4)                     * 'wrap' : value becomes value mod ``n``
274: (4)                     * 'clip' : values < 0 are mapped to 0, values > n-1 are mapped to n-
275: (4)                     1
276: (4)             Returns
277: (4)             -----
278: (4)             merged_array : array
279: (4)                 The merged result.
280: (4)             Raises
281: (4)             -----
282: (4)             ValueError: shape mismatch
283: (4)                 If `a` and each choice array are not all broadcastable to the same
284: (4)                 shape.
285: (4)             See Also
286: (4)             -----
287: (4)             ndarray.choose : equivalent method
288: (4)             numpy.take_along_axis : Preferable if `choices` is an array

```

```

285: (4)          Notes
286: (4)          -----
287: (4)          To reduce the chance of misinterpretation, even though the following
288: (4)          "abuse" is nominally supported, `choices` should neither be, nor be
289: (4)          thought of as, a single array, i.e., the outermost sequence-like container
290: (4)          should be either a list or a tuple.
291: (4)          Examples
292: (4)          -----
293: (4)          >>> choices = [[0, 1, 2, 3], [10, 11, 12, 13],
294: (4)          ... [20, 21, 22, 23], [30, 31, 32, 33]]
295: (4)          >>> np.choose([2, 3, 1, 0], choices
296: (4)          ... # the first element of the result will be the first element of the
297: (4)          ... # third (2+1) "array" in choices, namely, 20; the second element
298: (4)          ... # will be the second element of the fourth (3+1) choice array, i.e.,
299: (4)          ... # 31, etc.
300: (4)          ...
301: (4)          array([20, 31, 12, 3])
302: (4)          >>> np.choose([2, 4, 1, 0], choices, mode='clip') # 4 goes to 3 (4-1)
303: (4)          array([20, 31, 12, 3])
304: (4)          >>> # because there are 4 choice arrays
305: (4)          >>> np.choose([2, 4, 1, 0], choices, mode='wrap') # 4 goes to (4 mod 4)
306: (4)          array([20, 1, 12, 3])
307: (4)          >>> # i.e., 0
308: (4)          A couple examples illustrating how choose broadcasts:
309: (4)          >>> a = [[1, 0, 1], [0, 1, 0], [1, 0, 1]]
310: (4)          >>> choices = [-10, 10]
311: (4)          >>> np.choose(a, choices)
312: (4)          array([[ 10, -10,  10],
313: (11)          ... [-10,  10, -10],
314: (11)          ... [ 10, -10,  10]])
315: (4)          >>> # With thanks to Anne Archibald
316: (4)          >>> a = np.array([0, 1]).reshape((2,1,1))
317: (4)          >>> c1 = np.array([1, 2, 3]).reshape((1,3,1))
318: (4)          >>> c2 = np.array([-1, -2, -3, -4, -5]).reshape((1,1,5))
319: (4)          >>> np.choose(a, (c1, c2)) # result is 2x3x5, res[0,:,:]=c1, res[1,:,:]=c2
320: (4)          array([[[ 1,  1,  1,  1,  1],
321: (12)          ... [ 2,  2,  2,  2,  2],
322: (12)          ... [ 3,  3,  3,  3,  3]],
323: (11)          ... [[-1, -2, -3, -4, -5],
324: (12)          ... [-1, -2, -3, -4, -5],
325: (12)          ... [-1, -2, -3, -4, -5]]])
326: (4)          """

332: (4)          """
333: (4)          Repeat each element of an array after themselves
334: (4)          Parameters
335: (4)          -----
336: (4)          a : array_like
337: (8)          Input array.
338: (4)          repeats : int or array of ints
339: (8)          The number of repetitions for each element. `repeats` is broadcasted
340: (8)          to fit the shape of the given axis.
341: (4)          axis : int, optional
342: (8)          The axis along which to repeat values. By default, use the
343: (8)          flattened input array, and return a flat output array.
344: (4)          Returns
345: (4)          -----
346: (4)          repeated_array : ndarray
347: (8)          Output array which has the same shape as `a`, except along
348: (8)          the given axis.
349: (4)          See Also
350: (4)          -----
351: (4)          tile : Tile an array.
352: (4)          unique : Find the unique elements of an array.
353: (4)          Examples

```

```

354: (4)      -----
355: (4)      >>> np.repeat(3, 4)
356: (4)      array([3, 3, 3, 3])
357: (4)      >>> x = np.array([[1,2],[3,4]])
358: (4)      >>> np.repeat(x, 2)
359: (4)      array([1, 1, 2, 2, 3, 3, 4, 4])
360: (4)      >>> np.repeat(x, 3, axis=1)
361: (4)      array([[1, 1, 1, 2, 2, 2],
362: (11)      [3, 3, 3, 4, 4, 4]])
363: (4)      >>> np.repeat(x, [1, 2], axis=0)
364: (4)      array([[1, 2],
365: (11)      [3, 4],
366: (11)      [3, 4]])
367: (4)      """
368: (4)      return _wrapfunc(a, 'repeat', repeats, axis=axis)
369: (0)      def _put_dispatcher(a, ind, v, mode=None):
370: (4)          return (a, ind, v)
371: (0)      @array_function_dispatch(_put_dispatcher)
372: (0)      def put(a, ind, v, mode='raise'):
373: (4)          """
374: (4)          Replaces specified elements of an array with given values.
375: (4)          The indexing works on the flattened target array. `put` is roughly
376: (4)          equivalent to:
377: (4)          ::
378: (8)              a.flat[ind] = v
379: (4)      Parameters
380: (4)      -----
381: (4)      a : ndarray
382: (8)          Target array.
383: (4)      ind : array_like
384: (8)          Target indices, interpreted as integers.
385: (4)      v : array_like
386: (8)          Values to place in `a` at target indices. If `v` is shorter than
387: (8)          `ind` it will be repeated as necessary.
388: (4)      mode : {'raise', 'wrap', 'clip'}, optional
389: (8)          Specifies how out-of-bounds indices will behave.
390: (8)          * 'raise' -- raise an error (default)
391: (8)          * 'wrap' -- wrap around
392: (8)          * 'clip' -- clip to the range
393: (8)          'clip' mode means that all indices that are too large are replaced
394: (8)          by the index that addresses the last element along that axis. Note
395: (8)          that this disables indexing with negative numbers. In 'raise' mode,
396: (8)          if an exception occurs the target array may still be modified.

423: (4)           Interchange two axes of an array.
424: (4)           Parameters
425: (4)           -----
426: (4)           a : array_like
427: (8)           Input array.
428: (4)           axis1 : int
429: (8)           First axis.
430: (4)           axis2 : int
431: (8)           Second axis.
432: (4)           Returns
433: (4)           -----
434: (4)           a_swapped : ndarray
435: (8)           For NumPy >= 1.10.0, if `a` is an ndarray, then a view of `a` is
436: (8)           returned; otherwise a new array is created. For earlier NumPy
437: (8)           versions a view of `a` is returned only if the order of the
438: (8)           axes is changed, otherwise the input array is returned.
439: (4)           Examples
440: (4)           -----
441: (4)           >>> x = np.array([[1,2,3]])
442: (4)           >>> np.swapaxes(x,0,1)
443: (4)           array([[1],
444: (11)          [2],
445: (11)          [3]])
446: (4)           >>> x = np.array([[[0,1],[2,3]],[[4,5],[6,7]]])
447: (4)           >>> x
448: (4)           array([[[0, 1],
449: (12)          [2, 3]],
450: (11)          [[4, 5],
451: (12)          [6, 7]]])
452: (4)           >>> np.swapaxes(x,0,2)
453: (4)           array([[[0, 4],
454: (12)          [2, 6]],
455: (11)          [[1, 5],
456: (12)          [3, 7]]])
457: (4)           """
458: (4)           return _wrapfunc(a, 'swapaxes', axis1, axis2)
459: (0)           def _transpose_dispatcher(a, axes=None):
460: (4)           return (a,)
461: (0)           @array_function_dispatch(_transpose_dispatcher)
462: (0)           def transpose(a, axes=None):
463: (4)           """
464: (4)           Returns an array with axes transposed.
465: (4)           For a 1-D array, this returns an unchanged view of the original array, as
a
466: (4)           transposed vector is simply the same vector.
467: (4)           To convert a 1-D array into a 2-D column vector, an additional dimension
468: (4)           must be added, e.g., ``np.atleast2d(a).T`` achieves this, as does
469: (4)           ``a[:, np.newaxis]``.
470: (4)           For a 2-D array, this is the standard matrix transpose.
471: (4)           For an n-D array, if axes are given, their order indicates how the
472: (4)           axes are permuted (see Examples). If axes are not provided, then
473: (4)           ``transpose(a).shape == a.shape[::-1]``.
474: (4)           Parameters
475: (4)           -----
476: (4)           a : array_like
477: (8)           Input array.
478: (4)           axes : tuple or list of ints, optional
479: (8)           If specified, it must be a tuple or list which contains a permutation
480: (8)           of [0,1,...,N-1] where N is the number of axes of `a`. The `i`'th axis
481: (8)           of the returned array will correspond to the axis numbered ``axes[i]``
482: (8)           of the input. If not specified, defaults to ``range(a.ndim)[::-1]``,
483: (8)           which reverses the order of the axes.
484: (4)           Returns
485: (4)           -----
486: (4)           p : ndarray
487: (8)           `a` with its axes permuted. A view is returned whenever possible.
488: (4)           See Also
489: (4)           -----
490: (4)           ndarray.transpose : Equivalent method.

```

```

491: (4) moveaxis : Move axes of an array to new positions.
492: (4) argsort : Return the indices that would sort an array.
493: (4) Notes -----
495: (4) Use ``transpose(a, argsort(axes))`` to invert the transposition of tensors
496: (4) when using the `axes` keyword argument.
497: (4) Examples -----
499: (4) >>> a = np.array([[1, 2], [3, 4]])
500: (4) >>> a
501: (4) array([[1, 2],
502: (11)      [3, 4]])
503: (4) >>> np.transpose(a)
504: (4) array([[1, 3],
505: (11)      [2, 4]])
506: (4) >>> a = np.array([1, 2, 3, 4])
507: (4) >>> a
508: (4) array([1, 2, 3, 4])
509: (4) >>> np.transpose(a)
510: (4) array([1, 2, 3, 4])
511: (4) >>> a = np.ones((1, 2, 3))
512: (4) >>> np.transpose(a, (1, 0, 2)).shape
513: (4) (2, 1, 3)
514: (4) >>> a = np.ones((2, 3, 4, 5))
515: (4) >>> np.transpose(a).shape
516: (4) (5, 4, 3, 2)
517: (4) """
518: (4)     return _wrapfunc(a, 'transpose', axes)
519: (0) def _partition_dispatcher(a, kth, axis=None, kind=None, order=None):
520: (4)     return (a,)
521: (0) @array_function_dispatch(_partition_dispatcher)
522: (0) def partition(a, kth, axis=-1, kind='introselect', order=None):
523: (4) """
524: (4)     Return a partitioned copy of an array.
525: (4)     Creates a copy of the array with its elements rearranged in such a
526: (4)     way that the value of the element in k-th position is in the position
527: (4)     the value would be in a sorted array. In the partitioned array, all
528: (4)     elements before the k-th element are less than or equal to that
529: (4)     element, and all the elements after the k-th element are greater than
530: (4)     or equal to that element. The ordering of the elements in the two
531: (4)     partitions is undefined.
532: (4) .. versionadded:: 1.8.0
533: (4) Parameters -----
534: (4) a : array_like
535: (4)     Array to be sorted.
536: (8) kth : int or sequence of ints
537: (4)     Element index to partition by. The k-th value of the element
538: (8)     will be in its final sorted position and all smaller elements
539: (8)     will be moved before it and all equal or greater elements behind
540: (8)     it. The order of all elements in the partitions is undefined. If
541: (8)     provided with a sequence of k-th it will partition all elements
542: (8)     indexed by k-th of them into their sorted position at once.
543: (8) .. deprecated:: 1.22.0
544: (8)     Passing booleans as index is deprecated.
545: (12) axis : int or None, optional
546: (4)     Axis along which to sort. If None, the array is flattened before
547: (8)     sorting. The default is -1, which sorts along the last axis.
548: (8) kind : {'introselect'}, optional
549: (4)     Selection algorithm. Default is 'introselect'.
550: (8) order : str or list of str, optional
551: (4)     When `a` is an array with fields defined, this argument
552: (8)     specifies which fields to compare first, second, etc. A single
553: (8)     field can be specified as a string. Not all fields need be
554: (8)     specified, but unspecified fields will still be used, in the
555: (8)     order in which they come up in the dtype, to break ties.
556: (8) Returns -----
557: (4)     partitioned_array : ndarray

```

```

560: (8)                                Array of the same type and shape as `a` .
561: (4)                                See Also
562: (4)
563: (4)                                ndarray.partition : Method to sort an array in-place.
564: (4)                                argpartition : Indirect partition.
565: (4)                                sort : Full sorting
566: (4)                                Notes
567: (4)
568: (4)                                The various selection algorithms are characterized by their average
569: (4)                                speed, worst case performance, work space size, and whether they are
570: (4)                                stable. A stable sort keeps items with the same key in the same
571: (4)                                relative order. The available algorithms have the following
572: (4)                                properties:
573: (4)                                ===== ===== ===== ===== ===== =====
574: (7)          kind      speed   worst case   work space   stable
575: (4)
576: (4)          'introselect'    1        O(n)        0        no
577: (4)
578: (4)                                All the partition algorithms make temporary copies of the data when
579: (4)                                partitioning along any but the last axis. Consequently,
580: (4)                                partitioning along the last axis is faster and uses less space than
581: (4)                                partitioning along any other axis.
582: (4)                                The sort order for complex numbers is lexicographic. If both the
583: (4)                                real and imaginary parts are non-nan then the order is determined by
584: (4)                                the real parts except when they are equal, in which case the order
585: (4)                                is determined by the imaginary parts.
586: (4)                                Examples
587: (4)
588: (4)                                >>> a = np.array([7, 1, 7, 7, 1, 5, 7, 2, 3, 2, 6, 2, 3, 0])
589: (4)                                >>> p = np.partition(a, 4)
590: (4)                                >>> p
591: (4)                                array([0, 1, 2, 1, 2, 5, 2, 3, 3, 6, 7, 7, 7, 7])
592: (4)                                ``p[4]`` is 2; all elements in ``p[:4]`` are less than or equal
593: (4)                                to ``p[4]``, and all elements in ``p[5:]`` are greater than or
594: (4)                                equal to ``p[4]``. The partition is::
595: (8)                                [0, 1, 2, 1], [2], [5, 2, 3, 3, 6, 7, 7, 7, 7]
596: (4)                                The next example shows the use of multiple values passed to `kth` .
597: (4)                                >>> p2 = np.partition(a, (4, 8))
598: (4)                                >>> p2
599: (4)                                array([0, 1, 2, 1, 2, 3, 3, 2, 5, 6, 7, 7, 7, 7])
600: (4)                                ``p2[4]`` is 2 and ``p2[8]`` is 5. All elements in ``p2[:4]``
601: (4)                                are less than or equal to ``p2[4]``, all elements in ``p2[5:8]``
602: (4)                                are greater than or equal to ``p2[4]`` and less than or equal to
603: (4)                                ``p2[8]``, and all elements in ``p2[9:]`` are greater than or
604: (4)                                equal to ``p2[8]``. The partition is::
605: (8)                                [0, 1, 2, 1], [2], [3, 3, 2], [5], [6, 7, 7, 7, 7]
606: (4)                                """
607: (4)                                if axis is None:
608: (8)                                    a = asanyarray(a).flatten()
609: (8)                                    axis = -1
610: (4)                                else:

666: (4)           -----
667: (4)           One dimensional array:
668: (4)           >>> x = np.array([3, 4, 2, 1])
669: (4)           >>> x[np.argpartition(x, 3)]
670: (4)           array([2, 1, 3, 4])
671: (4)           >>> x[np.argpartition(x, (1, 3))]
672: (4)           array([1, 2, 3, 4])
673: (4)           >>> x = [3, 4, 2, 1]
674: (4)           >>> np.array(x)[np.argpartition(x, 3)]
675: (4)           array([2, 1, 3, 4])
676: (4)           Multi-dimensional array:
677: (4)           >>> x = np.array([[3, 4, 2], [1, 3, 1]])
678: (4)           >>> index_array = np.argpartition(x, kth=1, axis=-1)
679: (4)           >>> np.take_along_axis(x, index_array, axis=-1) # same as np.partition(x,
kth=1)
680: (4)           array([[2, 3, 4],
681: (11)             [1, 1, 3]])
682: (4)           """
683: (4)           return _wrapfunc(a, 'argpartition', kth, axis=axis, kind=kind,
order=order)
684: (0)           def _sort_dispatcher(a, axis=None, kind=None, order=None):
685: (4)               return (a,)
686: (0)           @array_function_dispatch(_sort_dispatcher)
687: (0)           def sort(a, axis=-1, kind=None, order=None):
688: (4)               """
689: (4)               Return a sorted copy of an array.
690: (4)               Parameters
691: (4)               -----
692: (4)               a : array_like
693: (8)                   Array to be sorted.
694: (4)               axis : int or None, optional

```

```

695: (8) Axis along which to sort. If None, the array is flattened before
696: (8) sorting. The default is -1, which sorts along the last axis.
697: (4) kind : {'quicksort', 'mergesort', 'heapsort', 'stable'}, optional
698: (8) Sorting algorithm. The default is 'quicksort'. Note that both 'stable'
699: (8) and 'mergesort' use timsort or radix sort under the covers and, in
general,
700: (8) the actual implementation will vary with data type. The 'mergesort'
option
701: (8) is retained for backwards compatibility.
702: (8) .. versionchanged:: 1.15.0.
703: (11) The 'stable' option was added.
704: (4) order : str or list of str, optional
705: (8) When `a` is an array with fields defined, this argument specifies
706: (8) which fields to compare first, second, etc. A single field can
707: (8) be specified as a string, and not all fields need be specified,
708: (8) but unspecified fields will still be used, in the order in which
709: (8) they come up in the dtype, to break ties.
710: (4) Returns
711: (4)
712: (4) -----
713: (8) sorted_array : ndarray
714: (4)     Array of the same type and shape as `a`.
See Also
715: (4) -----
716: (4) ndarray.sort : Method to sort an array in-place.
717: (4) argsort : Indirect sort.
718: (4) lexsort : Indirect stable sort on multiple keys.
719: (4) searchsorted : Find elements in a sorted array.
720: (4) partition : Partial sort.
721: (4) Notes
722: (4) -----
723: (4) The various sorting algorithms are characterized by their average speed,
724: (4) worst case performance, work space size, and whether they are stable. A
725: (4) stable sort keeps items with the same key in the same relative
726: (4) order. The four algorithms implemented in NumPy have the following
727: (4) properties:
728: (4) ====== ====== ====== ====== ====== ======
729: (7) kind      speed    worst case   work space   stable
730: (4) ====== ====== ====== ====== ====== ======
731: (4) 'quicksort'   1      O(n^2)          0        no
732: (4) 'heapsort'    3      O(n*log(n))    0        no
733: (4) 'mergesort'   2      O(n*log(n))  ~n/2      yes
734: (4) 'timsort'     2      O(n*log(n))  ~n/2      yes
735: (4) ====== ====== ====== ====== ====== ======
736: (4) .. note:: The datatype determines which of 'mergesort' or 'timsort'
737: (7) is actually used, even if 'mergesort' is specified. User selection
738: (7) at a finer scale is not currently available.
All the sort algorithms make temporary copies of the data when
739: (4) sorting along any but the last axis. Consequently, sorting along
740: (4) the last axis is faster and uses less space than sorting along
741: (4) any other axis.
742: (4) The sort order for complex numbers is lexicographic. If both the real
743: (4) and imaginary parts are non-nan then the order is determined by the
744: (4) real parts except when they are equal, in which case the order is
745: (4) determined by the imaginary parts.
746: (4) Previous to numpy 1.4.0 sorting real and complex arrays containing nan
747: (4) values led to undefined behaviour. In numpy versions >= 1.4.0 nan
748: (4) values are sorted to the end. The extended sort order is:
749: (4)     * Real: [R, nan]
750: (6)     * Complex: [R + Rj, R + nanj, nan + Rj, nan + nanj]
751: (6) where R is a non-nan real value. Complex values with the same nan
752: (4) placements are sorted according to the non-nan part if it exists.
753: (4) Non-nan values are sorted as before.
754: (4) .. versionadded:: 1.12.0
755: (4) quicksort has been changed to `introsort
<https://en.wikipedia.org/wiki/Introsort>`_.
756: (4) When sorting does not make enough progress it switches to
757: (4) `heapsort <https://en.wikipedia.org/wiki/Heapsort>`_.
758: (4) This implementation makes quicksort O(n*log(n)) in the worst case.
759: (4) 'stable' automatically chooses the best stable sorting algorithm
760: (4)

```

```

761: (4)           for the data type being sorted.
762: (4)           It, along with 'mergesort' is currently mapped to
763: (4)           `timsort <https://en.wikipedia.org/wiki/Timsort>`_
764: (4)           or `radix sort <https://en.wikipedia.org/wiki/Radix\_sort>`_
765: (4)           depending on the data type.
766: (4)           API forward compatibility currently limits the
767: (4)           ability to select the implementation and it is hardwired for the different
768: (4)           data types.
769: (4)           .. versionadded:: 1.17.0
770: (4)           Timsort is added for better performance on already or nearly
771: (4)           sorted data. On random data timsort is almost identical to
772: (4)           mergesort. It is now used for stable sort while quicksort is still the
773: (4)           default sort if none is chosen. For timsort details, refer to
774: (4)           `CPython listsort.txt
<https://github.com/python/cpython/blob/3.7/Objects/listsort.txt>`.
775: (4)           'mergesort' and 'stable' are mapped to radix sort for integer data types.

Radix sort is an
776: (4)           O(n) sort instead of O(n log n).
777: (4)           .. versionchanged:: 1.18.0
778: (4)           NaT now sorts to the end of arrays for consistency with NaN.
779: (4)           Examples
780: (4)           -----
781: (4)           >>> a = np.array([[1,4],[3,1]])
782: (4)           >>> np.sort(a)                      # sort along the last axis
783: (4)           array([[1, 4],
784: (11)             [1, 3]])
785: (4)           >>> np.sort(a, axis=None)      # sort the flattened array
786: (4)           array([1, 1, 3, 4])
787: (4)           >>> np.sort(a, axis=0)        # sort along the first axis
788: (4)           array([[1, 1],
789: (11)             [3, 4]])
790: (4)           Use the `order` keyword to specify a field to use when sorting a
791: (4)           structured array:
792: (4)           >>> dtype = [('name', 'S10'), ('height', float), ('age', int)]
793: (4)           >>> values = [('Arthur', 1.8, 41), ('Lancelot', 1.9, 38),
794: (4)                         ...          ('Galahad', 1.7, 38)]
795: (4)           >>> a = np.array(values, dtype=dtype)      # create a structured array
796: (4)           >>> np.sort(a, order='height')            # doctest: +SKIP
797: (4)           array([('Galahad', 1.7, 38), ('Arthur', 1.8, 41),
798: (11)               ('Lancelot', 1.8999999999999999, 38)],
799: (10)                 dtype=[('name', '|S10'), ('height', '<f8'), ('age', '<i4')])
800: (4)           Sort by age, then height if ages are equal:
801: (4)           >>> np.sort(a, order=['age', 'height'])       # doctest: +SKIP
802: (4)           array([('Galahad', 1.7, 38), ('Lancelot', 1.8999999999999999, 38),
803: (11)                     ('Arthur', 1.8, 41)],
804: (10)                   dtype=[('name', '|S10'), ('height', '<f8'), ('age', '<i4')])
805: (4)           """
806: (4)           if axis is None:
807: (8)               a = asanyarray(a).flatten()
808: (8)               axis = -1
809: (4)           else:
810: (8)               a = asanyarray(a).copy(order="K")
811: (4)               a.sort(axis=axis, kind=kind, order=order)
812: (4)               return a
813: (0)           def _argsort_dispatcher(a, axis=None, kind=None, order=None):
814: (4)               return (a,)
815: (0)           @array_function_dispatch(_argsort_dispatcher)
816: (0)           def argsort(a, axis=-1, kind=None, order=None):
817: (4)               """
818: (4)               Returns the indices that would sort an array.
819: (4)               Perform an indirect sort along the given axis using the algorithm
specified
820: (4)               by the `kind` keyword. It returns an array of indices of the same shape as
821: (4)               `a` that index data along the given axis in sorted order.
822: (4)               Parameters
823: (4)               -----
824: (4)               a : array_like
825: (8)                   Array to sort.
826: (4)               axis : int or None, optional

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

827: (8) Axis along which to sort. The default is -1 (the last axis). If None,
828: (8) the flattened array is used.
829: (4) kind : {'quicksort', 'mergesort', 'heapsort', 'stable'}, optional
830: (8) Sorting algorithm. The default is 'quicksort'. Note that both 'stable'
831: (8) and 'mergesort' use timsort under the covers and, in general, the
832: (8) actual implementation will vary with data type. The 'mergesort' option
833: (8) is retained for backwards compatibility.
834: (8) .. versionchanged:: 1.15.0.
835: (11) The 'stable' option was added.
836: (4) order : str or list of str, optional
837: (8) When `a` is an array with fields defined, this argument specifies
838: (8) which fields to compare first, second, etc. A single field can
839: (8) be specified as a string, and not all fields need be specified,
840: (8) but unspecified fields will still be used, in the order in which
841: (8) they come up in the dtype, to break ties.
842: (4) Returns
843: (4)
844: (4) index_array : ndarray, int
845: (8) Array of indices that sort `a` along the specified `axis`.
846: (8) If `a` is one-dimensional, ``a[index_array]`` yields a sorted `a`.
847: (8) More generally, ``np.take_along_axis(a, index_array, axis=axis)``
848: (8) always yields the sorted `a`, irrespective of dimensionality.
849: (4) See Also
850: (4)
851: (4) sort : Describes sorting algorithms used.
852: (4) lexsort : Indirect stable sort with multiple keys.
853: (4) ndarray.sort : Inplace sort.
854: (4) argpartition : Indirect partial sort.
855: (4) take_along_axis : Apply ``index_array`` from argsort
856: (22) to an array as if by calling sort.
857: (4) Notes
858: (4)
859: (4) See `sort` for notes on the different sorting algorithms.
860: (4) As of NumPy 1.4.0 `argsort` works with real/complex arrays containing
861: (4) nan values. The enhanced sort order is documented in `sort`.
862: (4) Examples
863: (4)
864: (4) One dimensional array:
865: (4) >>> x = np.array([3, 1, 2])
866: (4) >>> np.argsort(x)
867: (4) array([1, 2, 0])
868: (4) Two-dimensional array:
869: (4) >>> x = np.array([[0, 3], [2, 2]])
870: (4) >>> x
871: (4) array([[0, 3],
872: (11)           [2, 2]])
873: (4) >>> ind = np.argsort(x, axis=0) # sorts along first axis (down)
874: (4) >>> ind
875: (4) array([[0, 1],
876: (11)           [1, 0]])
877: (4) >>> np.take_along_axis(x, ind, axis=0) # same as np.sort(x, axis=0)
878: (4) array([[0, 2],
879: (11)           [2, 3]])
880: (4) >>> ind = np.argsort(x, axis=1) # sorts along last axis (across)
881: (4) >>> ind
882: (4) array([[0, 1],
883: (11)           [0, 1]])
884: (4) >>> np.take_along_axis(x, ind, axis=1) # same as np.sort(x, axis=1)
885: (4) array([[0, 3],
886: (11)           [2, 2]])
887: (4) Indices of the sorted elements of a N-dimensional array:
888: (4) >>> ind = np.unravel_index(np.argsort(x, axis=None), x.shape)
889: (4) >>> ind
890: (4) (array([0, 1, 1, 0]), array([0, 0, 1, 1]))
891: (4) >>> x[ind] # same as np.sort(x, axis=None)
892: (4) array([0, 2, 2, 3])
893: (4) Sorting with keys:
894: (4) >>> x = np.array([(1, 0), (0, 1)], dtype=[('x', '<i4'), ('y', '<i4')])
895: (4) >>> x

    >>> np.argsort(x, order=('y','x'))
    array([0, 1])
    """
    return _wrapfunc(a, 'argsort', axis=axis, kind=kind, order=order)
def _argmax_dispatcher(a, axis=None, out=None, *, keepdims=np._NoValue):
    return (a, out)
@array_function_dispatch(_argmax_dispatcher)
def argmax(a, axis=None, out=None, *, keepdims=np._NoValue):
    """
    Returns the indices of the maximum values along an axis.

    Parameters
    -----
    a : array_like
        Input array.
    axis : int, optional
        By default, the index is into the flattened array, otherwise
        along the specified axis.
    out : array, optional
        If provided, the result will be inserted into this array. It should
        be of the appropriate shape and dtype.
    keepdims : bool, optional
        If this is set to True, the axes which are reduced are left
        in the result as dimensions with size one. With this option,
        the result will broadcast correctly against the array.
        .. versionadded:: 1.22.0
    Returns
    -----
    index_array : ndarray of ints
        Array of indices into the array. It has the same shape as `a.shape`
        with the dimension along `axis` removed. If `keepdims` is set to True,
        then the size of `axis` will be 1 with the resulting array having same
        shape as `a.shape`.
    See Also
    -----
    ndarray.argmax, argmin
    amax : The maximum value along a given axis.
    unravel_index : Convert a flat index into an index tuple.
    take_along_axis : Apply ``np.expand_dims(index_array, axis)``
                      from argmax to an array as if by calling max.
    Notes
    -----
    In case of multiple occurrences of the maximum values, the indices
    corresponding to the first occurrence are returned.
    Examples
    -----
    >>> a = np.arange(6).reshape(2,3) + 10
    >>> a
    array([[10, 11, 12],
           [13, 14, 15]])
    >>> np.argmax(a)
    5
    >>> np.argmax(a, axis=0)
    array([1, 1, 1])
    >>> np.argmax(a, axis=1)
    array([2, 2])
    Indexes of the maximal elements of a N-dimensional array:
    >>> ind = np.unravel_index(np.argmax(a, axis=None), a.shape)
    >>> ind
    (1, 2)
    >>> a[ind]
    15
    >>> b = np.arange(6)
    >>> b[1] = 5
    >>> b
    array([0, 5, 2, 3, 4, 5])

```

`bisect.bisect_left` -----
sort : Return a sorted copy of an array.
histogram : Produce histogram from 1-D data.
Notes -----
Binary search is used to find the required insertion points.
As of NumPy 1.4.0 `searchsorted` works with real/complex arrays containing
`nan` values. The enhanced sort order is documented in `sort`.
This function uses the same algorithm as the builtin python

(``side='left'``) and `bisect.bisect_right` (``side='right'``) functions,
which is also vectorized in the `v` argument.
Examples -----
>>> np.searchsorted([1,2,3,4,5], 3)
2
>>> np.searchsorted([1,2,3,4,5], 3, side='right')
3
>>> np.searchsorted([1,2,3,4,5], [-10, 10, 2, 3])
array([0, 5, 1, 2])
"""
return _wrapfunc(a, 'searchsorted', v, side=side, sorter=sorter)
def _resize_dispatcher(a, new_shape):
    return (a,)
@array_function_dispatch(_resize_dispatcher)
def resize(a, new_shape):
    """
    Return a new array with the specified shape.
    If the new array is larger than the original array, then the new
    array is filled with repeated copies of `a`. Note that this behavior
    is different from a.resize(new_shape) which fills with zeros instead
    of repeated copies of `a`.
    Parameters
    -----
    a : array_like
        Array to be resized.
    new_shape : int or tuple of int
        Shape of resized array.
    Returns
    -----
    reshaped_array : ndarray
        The new array is formed from the data in the old array, repeated
        if necessary to fill out the required number of elements. The
        data are repeated iterating over the array in C-order.
See Also
-----
numpy.reshape : Reshape an array without changing the total size.
numpy.pad : Enlarge and pad an array.
numpy.repeat : Repeat elements of an array.
ndarray.resize : resize an array in-place.
Notes -----
When the total size of the array does not change `~numpy.reshape` should
be used. In most other cases either indexing (to reduce the size)
or padding (to increase the size) may be a more appropriate solution.
Warning: This functionality does **not** consider axes separately,
i.e. it does not apply interpolation/extrapolation.
It fills the return array with the required number of elements, iterating
over `a` in C-order, disregarding axes (and cycling back from the start if
the new shape is larger). This functionality is therefore not suitable to
resize images, or data where each axis represents a separate and distinct
entity.
Examples -----
>>> a=np.array([[0,1],[2,3]])
>>> np.resize(a,(2,3))
array([[0, 1, 2],
       [3, 0, 1]])

1249: (4)          else:
1250: (8)              return squeeze(axis=axis)
1251: (0)          def _diagonal_dispatcher(a, offset=None, axis1=None, axis2=None):
1252: (4)              return (a,)
1253: (0)          @array_function_dispatch(_diagonal_dispatcher)
1254: (0)          def diagonal(a, offset=0, axis1=0, axis2=1):
1255: (4)              """
1256: (4)              Return specified diagonals.
1257: (4)              If `a` is 2-D, returns the diagonal of `a` with the given offset,
1258: (4)              i.e., the collection of elements of the form ``a[i, i+offset]``. If
1259: (4)              `a` has more than two dimensions, then the axes specified by `axis1`
1260: (4)              and `axis2` are used to determine the 2-D sub-array whose diagonal is
1261: (4)              returned. The shape of the resulting array can be determined by
1262: (4)              removing `axis1` and `axis2` and appending an index to the right equal
1263: (4)              to the size of the resulting diagonals.
1264: (4)              In versions of NumPy prior to 1.7, this function always returned a new,
1265: (4)              independent array containing a copy of the values in the diagonal.
1266: (4)              In NumPy 1.7 and 1.8, it continues to return a copy of the diagonal,
1267: (4)              but depending on this fact is deprecated. Writing to the resulting
1268: (4)              array continues to work as it used to, but a FutureWarning is issued.
1269: (4)              Starting in NumPy 1.9 it returns a read-only view on the original array.
1270: (4)              Attempting to write to the resulting array will produce an error.
1271: (4)              In some future release, it will return a read/write view and writing to
1272: (4)              the returned array will alter your original array. The returned array
1273: (4)              will have the same type as the input array.
1274: (4)              If you don't write to the array returned by this function, then you can
1275: (4)              just ignore all of the above.
1276: (4)              If you depend on the current behavior, then we suggest copying the
1277: (4)              returned array explicitly, i.e., use ``np.diagonal(a).copy()`` instead
1278: (4)              of just ``np.diagonal(a)``. This will work with both past and future
1279: (4)              versions of NumPy.
1280: (4)          Parameters
1281: (4)          -----
1282: (4)          a : array_like
1283: (8)              Array from which the diagonals are taken.
1284: (4)          offset : int, optional
1285: (8)              Offset of the diagonal from the main diagonal. Can be positive or
1286: (8)              negative. Defaults to main diagonal (0).
1287: (4)          axis1 : int, optional
1288: (8)              Axis to be used as the first axis of the 2-D sub-arrays from which
1289: (8)              the diagonals should be taken. Defaults to first axis (0).
1290: (4)          axis2 : int, optional
1291: (8)              Axis to be used as the second axis of the 2-D sub-arrays from
1292: (8)              which the diagonals should be taken. Defaults to second axis (1).
1293: (4)          Returns
1294: (4)          -----
1295: (4)          array_of_diagonals : ndarray
1296: (8)              If `a` is 2-D, then a 1-D array containing the diagonal and of the
1297: (8)              same type as `a` is returned unless `a` is a `matrix`, in which case
1298: (8)              a 1-D array rather than a (2-D) `matrix` is returned in order to
1299: (8)              maintain backward compatibility.
1300: (8)              If ``a.ndim > 2``, then the dimensions specified by `axis1` and
1301: (8)              `axis2`
1302: (8)              are removed, and a new axis inserted at the end corresponding to the
1303: (4)              diagonal.

-----  

ValueError  

    If the dimension of `a` is less than 2.  

See Also  

-----  

diag : MATLAB work-a-like for 1-D and 2-D arrays.  

diagflat : Create diagonal arrays.  

trace : Sum along diagonals.  

Examples  

-----  

>>> a = np.arange(4).reshape(2,2)  

>>> a  

array([[0, 1],  

       [2, 3]])  

>>> a.diagonal()  

array([0, 3])  

>>> a.diagonal(1)  

array([1])  

A 3-D example:  

>>> a = np.arange(8).reshape(2,2,2); a  

array([[[0, 1],  

        [2, 3]],  

       [[4, 5],  

        [6, 7]]])  

>>> a.diagonal(0, # Main diagonals of two arrays created by skipping  

...          0, # across the outer(left)-most axis last and  

...          1) # the "middle" (row) axis first.  

array([[0, 6],  

       [1, 7]])  

The sub-arrays whose main diagonals we just obtained; note that each  

corresponds to fixing the right-most (column) axis, and that the  

diagonals are "packed" in rows.  

>>> a[:, :, 0] # main diagonal is [0 6]  

array([[0, 2],  

       [4, 6]])  

>>> a[:, :, 1] # main diagonal is [1 7]  

array([[1, 3],  

       [5, 7]])  

The anti-diagonal can be obtained by reversing the order of elements  

using either `numpy.flipud` or `numpy.fliplr`.  

>>> a = np.arange(9).reshape(3, 3)  

>>> a  

array([[0, 1, 2],  

       [3, 4, 5],  

       [6, 7, 8]])  

>>> np.fliplr(a).diagonal() # Horizontal flip  

array([2, 4, 6])  

>>> np.flipud(a).diagonal() # Vertical flip  

array([6, 4, 2])  

Note that the order in which the diagonal is retrieved varies depending  

on the flip function.  

"""  

if isinstance(a, np.matrix):  

    return asarray(a).diagonal(offset=offset, axis1=axis1, axis2=axis2)  

else:  

    return asanyarray(a).diagonal(offset=offset, axis1=axis1, axis2=axis2)  

def _trace_dispatcher(  

    a, offset=None, axis1=None, axis2=None, dtype=None, out=None):  

    return (a, out)  

@array_function_dispatch(_trace_dispatcher)  

def trace(a, offset=0, axis1=0, axis2=1, dtype=None, out=None):  

    """  

    Return the sum along diagonals of the array.  

    If `a` is 2-D, the sum along its diagonal with the given offset  

    is returned, i.e., the sum of elements ``a[i,i+offset]`` for all i.  

    If `a` has more than two dimensions, then the axes specified by axis1 and  

    axis2 are used to determine the 2-D sub-arrays whose traces are returned.  

    The shape of the resulting array is the same as that of `a` with `axis1`  

    and `axis2` removed.

1425: (4)                         As of NumPy 1.10, the returned array will have the same type as the input
1426: (4)                         array. (for example, a masked array will be returned for a masked array
1427: (4)                         input)
1428: (4)                         Parameters
1429: (4)                         -----
1430: (4)                         a : array_like
1431: (8)                           Input array. The elements in `a` are read in the order specified by
1432: (8)                           `order`, and packed as a 1-D array.
1433: (4)                         order : {'C', 'F', 'A', 'K'}, optional
1434: (8)                           The elements of `a` are read using this index order. 'C' means
1435: (8)                           to index the elements in row-major, C-style order,
1436: (8)                           with the last axis index changing fastest, back to the first
1437: (8)                           axis index changing slowest. 'F' means to index the elements
1438: (8)                           in column-major, Fortran-style order, with the
1439: (8)                           first index changing fastest, and the last index changing
                           slowest. Note that the 'C' and 'F' options take no account of
                           the memory layout of the underlying array, and only refer to

```

```

1440: (8)          the order of axis indexing. 'A' means to read the elements in
1441: (8)          Fortran-like index order if `a` is Fortran *contiguous* in
1442: (8)          memory, C-like order otherwise. 'K' means to read the
1443: (8)          elements in the order they occur in memory, except for
1444: (8)          reversing the data when strides are negative. By default, 'C'
1445: (8)          index order is used.
1446: (4)          Returns
1447: (4)
1448: (4)          -----
1449: (8)          y : array_like
1450: (8)          y is a contiguous 1-D array of the same subtype as `a`,
1451: (8)          with shape ``a.size,``.
1452: (8)          Note that matrices are special cased for backward compatibility,
1453: (8)          if `a` is a matrix, then y is a 1-D ndarray.
1454: (4)          See Also
1455: (4)          -----
1456: (4)          ndarray.flat : 1-D iterator over an array.
1457: (22)          ndarray.flatten : 1-D array copy of the elements of an array
1458: (4)          in row-major order.
1459: (4)          ndarray.reshape : Change the shape of an array without changing its data.
1460: (4)          Notes
1461: (4)          -----
1462: (4)          In row-major, C-style order, in two dimensions, the row index
1463: (4)          varies the slowest, and the column index the quickest. This can
1464: (4)          be generalized to multiple dimensions, where row-major order
1465: (4)          implies that the index along the first axis varies slowest, and
1466: (4)          the index along the last quickest. The opposite holds for
1467: (4)          column-major, Fortran-style index ordering.
1468: (4)          When a view is desired in as many cases as possible, ``arr.reshape(-1)``
1469: (4)          may be preferable. However, ``ravel`` supports ``K`` in the optional
1470: (4)          ``order`` argument while ``reshape`` does not.
1471: (4)          Examples
1472: (4)          -----
1473: (4)          It is equivalent to ``reshape(-1, order=order)``.
1474: (4)          >>> x = np.array([[1, 2, 3], [4, 5, 6]])
1475: (4)          >>> np.ravel(x)
1476: (4)          array([1, 2, 3, 4, 5, 6])
1477: (4)          >>> x.reshape(-1)
1478: (4)          array([1, 2, 3, 4, 5, 6])
1479: (4)          >>> np.ravel(x, order='F')
1480: (4)          array([1, 4, 2, 5, 3, 6])
1481: (4)          When ``order`` is 'A', it will preserve the array's 'C' or 'F' ordering:
1482: (4)          >>> np.ravel(x.T)
1483: (4)          array([1, 4, 2, 5, 3, 6])
1484: (4)          >>> np.ravel(x.T, order='A')
1485: (4)          array([1, 2, 3, 4, 5, 6])
1486: (4)          When ``order`` is 'K', it will preserve orderings that are neither 'C'
1487: (4)          nor 'F', but won't reverse axes:
1488: (4)          >>> a = np.arange(3)[::-1]; a
1489: (4)          array([2, 1, 0])
1490: (4)          >>> a.ravel(order='C')
1491: (4)          array([2, 1, 0])
1492: (4)          >>> a.ravel(order='K')
1493: (4)          array([2, 1, 0])
1494: (4)          >>> a = np.arange(12).reshape(2,3,2).swapaxes(1,2); a
1495: (12)          array([[[ 0,  2,  4],

@array_function_dispatch(_nonzero_dispatcher)
def nonzero(a):
    """
    Return the indices of the elements that are non-zero.
    Returns a tuple of arrays, one for each dimension of `a`,
    containing the indices of the non-zero elements in that
    dimension. The values in `a` are always tested and returned in
    row-major, C-style order.
    To group the indices by element, rather than dimension, use `argwhere`,
    which returns a row for each non-zero element.
    .. note::
        When called on a zero-d array or scalar, ``nonzero(a)`` is treated
        as ``nonzero(atleast_1d(a))``.
        .. deprecated:: 1.17.0
            Use `atleast_1d` explicitly if this behavior is deliberate.
    Parameters
    -----
    a : array_like
        Input array.
    Returns
    -----
    tuple_of_arrays : tuple
        Indices of elements that are non-zero.
    See Also
    -----
    flatnonzero :
        Return indices that are non-zero in the flattened version of the input
        array.
    ndarray.nonzero :
        Equivalent ndarray method.
    count_nonzero :
        Counts the number of non-zero elements in the input array.
    Notes
    -----
    While the nonzero values can be obtained with ``a[nonzero(a)]``, it is
    recommended to use ``x[x.astype(bool)]`` or ``x[x != 0]`` instead, which
    will correctly handle 0-d arrays.
    Examples
    -----
    >>> x = np.array([[3, 0, 0], [0, 4, 0], [5, 6, 0]])
    >>> x
    array([[3, 0, 0],
           [0, 4, 0],
           [5, 6, 0]])
    >>> np.nonzero(x)
    (array([0, 1, 2, 2]), array([0, 1, 0, 1]))
    >>> x[np.nonzero(x)]
    array([3, 4, 5, 6])
    >>> np.transpose(np.nonzero(x))
    array([[0, 0],
           [1, 1],
           [2, 0],
           [2, 1]])
    A common use for ``nonzero`` is to find the indices of an array, where
    a condition is True. Given an array `a`, the condition `a > 3` is a
    boolean array and since False is interpreted as 0, np.nonzero(a > 3)
    yields the indices of the `a` where the condition is true.
    >>> a = np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
    >>> a > 3
    array([[False, False, False],
           [ True,  True,  True],
           [ True,  True,  True]])
    >>> np.nonzero(a > 3)
    (array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
    Using this result to index `a` is equivalent to using the mask directly:
    >>> a[np.nonzero(a > 3)]
    array([4, 5, 6, 7, 8, 9])
    >>> a[a > 3] # prefer this spelling
    array([4, 5, 6, 7, 8, 9])

```

```

1578: (4)           ``nonzero`` can also be called as a method of the array.
1579: (4)           >>> (a > 3).nonzero()
1580: (4)           (array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
1581: (4)
1582: (4)           """

Notes  

-----  

When `a_min` is greater than `a_max`, `clip` returns an array in which all values are equal to `a_max`, as shown in the second example.  

Examples  

-----  

>>> a = np.arange(10)  

>>> a  

array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])  

>>> np.clip(a, 1, 8)  

array([1, 1, 2, 3, 4, 5, 6, 7, 8, 8])  

>>> np.clip(a, 8, 1)  

array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1])  

>>> np.clip(a, 3, 6, out=a)  

array([3, 3, 3, 3, 4, 5, 6, 6, 6, 6])  

>>> a  

array([3, 3, 3, 3, 4, 5, 6, 6, 6, 6])  

>>> a = np.arange(10)  

>>> a  

array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])  

>>> np.clip(a, [3, 4, 1, 1, 1, 4, 4, 4, 4, 4], 8)  

array([3, 4, 2, 3, 4, 5, 6, 7, 8, 8])  

"""  

    return _wrapfunc(a, 'clip', a_min, a_max, out=out, **kwargs)  

def _sum_dispatcher(a, axis=None, dtype=None, out=None, keepdims=None,  

                    initial=None, where=None):  

    return (a, out)  

@array_function_dispatch(_sum_dispatcher)  

def sum(a, axis=None, dtype=None, out=None, keepdims=np._NoValue,  

       initial=np._NoValue, where=np._NoValue):  

    """  

        Sum of array elements over a given axis.  

Parameters  

-----  

a : array_like  

    Elements to sum.  

axis : None or int or tuple of ints, optional  

    Axis or axes along which a sum is performed. The default,  

    axis=None, will sum all of the elements of the input array. If  

    axis is negative it counts from the last to the first axis.  

.. versionadded:: 1.7.0  

    If axis is a tuple of ints, a sum is performed on all of the axes  

    specified in the tuple instead of a single axis or all the axes as  

    before.  

dtype : dtype, optional  

    The type of the returned array and of the accumulator in which the  

    elements are summed. The dtype of `a` is used by default unless `a`  

    has an integer dtype of less precision than the default platform  

    integer. In that case, if `a` is signed then the platform integer  

    is used while if `a` is unsigned then an unsigned integer of the  

    same precision as the platform integer is used.  

out : ndarray, optional  

    Alternative output array in which to place the result. It must have  

    the same shape as the expected output, but the type of the output  

    values will be cast if necessary.  

keepdims : bool, optional  

    If this is set to True, the axes which are reduced are left  

    in the result as dimensions with size one. With this option,  

    the result will broadcast correctly against the input array.  

    If the default value is passed, then `keepdims` will not be  

    passed through to the `sum` method of sub-classes of  

    `ndarray`, however any non-default value will be. If the  

    sub-class' method does not implement `keepdims` any  

    exceptions will be raised.  

initial : scalar, optional  

    Starting value for the sum. See `~numpy.ufunc.reduce` for details.

```

1785: (8) .. versionadded:: 1.15.0
1786: (4) where : array_like of bool, optional
1787: (8) Elements to include in the sum. See `~numpy.ufunc.reduce` for details.
1788: (8) .. versionadded:: 1.17.0
1789: (4) Returns
1790: (4) -----
1791: (4) sum_along_axis : ndarray
1792: (8) An array with the same shape as `a`, with the specified
1793: (8) axis removed. If `a` is a 0-d array, or if `axis` is None, a scalar
1794: (8) is returned. If an output array is specified, a reference to
1795: (8) `out` is returned.
1796: (4) See Also
1797: (4) -----
1798: (4) ndarray.sum : Equivalent method.
1799: (4) add.reduce : Equivalent functionality of `add`.
1800: (4) cumsum : Cumulative sum of array elements.
1801: (4) trapz : Integration of array values using the composite trapezoidal rule.
1802: (4) mean, average
1803: (4) Notes
1804: (4) -----
1805: (4) Arithmetic is modular when using integer types, and no error is
1806: (4) raised on overflow.
1807: (4) The sum of an empty array is the neutral element 0:
1808: (4) >>> np.sum([])
1809: (4) 0.0
1810: (4) For floating point numbers the numerical precision of sum (and
1811: (4) ``np.add.reduce``) is in general limited by directly adding each number
1812: (4) individually to the result causing rounding errors in every step.
1813: (4) However, often numpy will use a numerically better approach (partial
1814: (4) pairwise summation) leading to improved precision in many use-cases.
1815: (4) This improved precision is always provided when no ``axis`` is given.
1816: (4) When ``axis`` is given, it will depend on which axis is summed.
1817: (4) Technically, to provide the best speed possible, the improved precision
1818: (4) is only used when the summation is along the fast axis in memory.
1819: (4) Note that the exact precision may vary depending on other parameters.
1820: (4) In contrast to NumPy, Python's ``math.fsum`` function uses a slower but
1821: (4) more precise approach to summation.
1822: (4) Especially when summing a large number of lower precision floating point
1823: (4) numbers, such as ``float32``, numerical errors can become significant.
1824: (4) In such cases it can be advisable to use `dtype="float64"` to use a higher
1825: (4) precision for the output.
1826: (4) Examples
1827: (4) -----
1828: (4) >>> np.sum([0.5, 1.5])
1829: (4) 2.0
1830: (4) >>> np.sum([0.5, 0.7, 0.2, 1.5], dtype=np.int32)
1831: (4) 1
1832: (4) >>> np.sum([[0, 1], [0, 5]])
1833: (4) 6
1834: (4) >>> np.sum([[0, 1], [0, 5]], axis=0)
1835: (4) array([0, 6])
1836: (4) >>> np.sum([[0, 1], [0, 5]], axis=1)
1837: (4) array([1, 5])
1838: (4) >>> np.sum([[0, 1], [np.nan, 5]], where=[False, True], axis=1)
1839: (4) array([1., 5.])
1840: (4) If the accumulator is too small, overflow occurs:
1841: (4) >>> np.ones(128, dtype=np.int8).sum(dtype=np.int8)
1842: (4) -128
1843: (4) You can also start the sum with a value other than zero:
1844: (4) >>> np.sum([10], initial=5)
1845: (4) 15
1846: (4) """
1847: (4)     if isinstance(a, _gentype):
1848: (8)         warnings.warn(
1849: (12)             "Calling np.sum(generator) is deprecated, and in the future will
give a different result. "
1850: (12)             "Use np.sum(np.fromiter(generator)) or the python sum builtin
instead.",
1851: (12)             DeprecationWarning, stacklevel=2)

```

```

1852: (8)             res = _sum_(a)
1853: (8)             if out is not None:

1865: (4)     Test whether any array element along a given axis evaluates to True.
1866: (4)     Returns single boolean if `axis` is ``None``.
1867: (4)     Parameters
1868: (4)     -----
1869: (4)     a : array_like
1870: (8)         Input array or object that can be converted to an array.
1871: (4)     axis : None or int or tuple of ints, optional
1872: (8)         Axis or axes along which a logical OR reduction is performed.
1873: (8)         The default (``axis=None``) is to perform a logical OR over all
1874: (8)         the dimensions of the input array. `axis` may be negative, in
1875: (8)         which case it counts from the last to the first axis.
1876: (8)         .. versionadded:: 1.7.0
1877: (8)         If this is a tuple of ints, a reduction is performed on multiple
1878: (8)         axes, instead of a single axis or all the axes as before.
1879: (4)     out : ndarray, optional
1880: (8)         Alternate output array in which to place the result. It must have
1881: (8)         the same shape as the expected output and its type is preserved
1882: (8)         (e.g., if it is of type float, then it will remain so, returning
1883: (8)         1.0 for True and 0.0 for False, regardless of the type of `a`).
1884: (8)         See :ref:`ufuncs-output-type` for more details.
1885: (4)     keepdims : bool, optional
1886: (8)         If this is set to True, the axes which are reduced are left
1887: (8)         in the result as dimensions with size one. With this option,
1888: (8)         the result will broadcast correctly against the input array.
1889: (8)         If the default value is passed, then `keepdims` will not be
1890: (8)         passed through to the `any` method of sub-classes of
1891: (8)         `ndarray`, however any non-default value will be. If the
1892: (8)         sub-class' method does not implement `keepdims` any
1893: (8)         exceptions will be raised.
1894: (4)     where : array_like of bool, optional
1895: (8)         Elements to include in checking for any `True` values.
1896: (8)         See `~numpy.ufunc.reduce` for details.
1897: (8)         .. versionadded:: 1.20.0
1898: (4)     Returns
1899: (4)     -----
1900: (4)     any : bool or ndarray
1901: (8)         A new boolean or `ndarray` is returned unless `out` is specified,
1902: (8)         in which case a reference to `out` is returned.
1903: (4)     See Also

2008: (0) def cumsum(a, axis=None, dtype=None, out=None):
2009: (4) """
2010: (4)     Return the cumulative sum of the elements along a given axis.
2011: (4) Parameters
2012: (4) -----
2013: (4) a : array_like
2014: (8)     Input array.
2015: (4) axis : int, optional
2016: (8)     Axis along which the cumulative sum is computed. The default
2017: (8)     (None) is to compute the cumsum over the flattened array.
2018: (4) dtype : dtype, optional
2019: (8)     Type of the returned array and of the accumulator in which the
2020: (8)     elements are summed. If `dtype` is not specified, it defaults
2021: (8)     to the dtype of `a`, unless `a` has an integer dtype with a
2022: (8)     precision less than that of the default platform integer. In
2023: (8)     that case, the default platform integer is used.
2024: (4) out : ndarray, optional
2025: (8)     Alternative output array in which to place the result. It must
2026: (8)     have the same shape and buffer length as the expected output
2027: (8)     but the type will be cast if necessary. See :ref:`ufuncs-output-type`
for
2028: (8)     more details.
2029: (4) Returns
2030: (4) -----
2031: (4) cumsum_along_axis : ndarray.
2032: (8)     A new array holding the result is returned unless `out` is
2033: (8)     specified, in which case a reference to `out` is returned. The
2034: (8)     result has the same size as `a`, and the same shape as `a` if
2035: (8)     `axis` is not None or `a` is a 1-d array.
2036: (4) See Also
2037: (4) -----
2038: (4) sum : Sum array elements.
2039: (4) trapz : Integration of array values using the composite trapezoidal rule.
2040: (4) diff : Calculate the n-th discrete difference along given axis.
2041: (4) Notes
2042: (4) -----
2043: (4) Arithmetic is modular when using integer types, and no error is
2044: (4) raised on overflow.
2045: (4) ``cumsum(a)[-1]`` may not be equal to ``sum(a)`` for floating-point
2046: (4) values since ``sum`` may use a pairwise summation routine, reducing
2047: (4) the roundoff-error. See `sum` for more information.
2048: (4) Examples
2049: (4) -----
2050: (4) >>> a = np.array([[1,2,3], [4,5,6]])
2051: (4) >>> a
2052: (4) array([[1, 2, 3],
2053: (11)           [4, 5, 6]])
2054: (4) >>> np.cumsum(a)
2055: (4) array([ 1,  3,  6, 10, 15, 21])

>>> np.cumsum(a, dtype=float)      # specifies type of output value(s)
array([ 1.,   3.,   6.,  10.,  15.,  21.])
>>> np.cumsum(a, axis=0)         # sum over rows for each of the 3 columns
array([[1, 2, 3],
       [5, 7, 9]])
>>> np.cumsum(a, axis=1)         # sum over columns for each of the 2 rows
array([[ 1,   3,   6],
       [ 4,   9,  15]])
```cumsum(b)[-1]`` may not be equal to ``sum(b)``
>>> b = np.array([1, 2e-9, 3e-9] * 1000000)
>>> b.cumsum()[-1]
1000000.0050045159
>>> b.sum()
1000000.0050000029
"""
    return _wrapfunc(a, 'cumsum', axis=axis, dtype=dtype, out=out)
def _ptp_dispatcher(a, axis=None, out=None, keepdims=None):
    return (a, out)
@array_function_dispatch(_ptp_dispatcher)
def ptp(a, axis=None, out=None, keepdims=np._NoValue):
    """
    Range of values (maximum - minimum) along an axis.
    The name of the function comes from the acronym for 'peak to peak'.
    .. warning::
        `ptp` preserves the data type of the array. This means the
        return value for an input of signed integers with n bits
        (e.g. `np.int8`, `np.int16`, etc) is also a signed integer
        with n bits. In that case, peak-to-peak values greater than
        ``2**n-1`` will be returned as negative values. An example
        with a work-around is shown below.
    Parameters
    -----
    a : array_like
        Input values.
    axis : None or int or tuple of ints, optional
        Axis along which to find the peaks. By default, flatten the
        array. `axis` may be negative, in
        which case it counts from the last to the first axis.
        .. versionadded:: 1.15.0
        If this is a tuple of ints, a reduction is performed on multiple
        axes, instead of a single axis or all the axes as before.
    out : array_like
        Alternative output array in which to place the result. It must
        have the same shape and buffer length as the expected output,
        but the type of the output values will be cast if necessary.
    keepdims : bool, optional
        If this is set to True, the axes which are reduced are left
        in the result as dimensions with size one. With this option,
        the result will broadcast correctly against the input array.
        If the default value is passed, then `keepdims` will not be
        passed through to the `ptp` method of sub-classes of
        `ndarray`, however any non-default value will be. If the
        sub-class' method does not implement `keepdims` any
        exceptions will be raised.
    Returns
    -----
    ptp : ndarray or scalar
        The range of a given array - `scalar` if array is one-dimensional
        or a new array holding the result along the given axis
    Examples
    -----
    >>> x = np.array([[4, 9, 2, 10],
                      ...           [6, 9, 7, 12]])
    >>> np.ptp(x, axis=1)
    array([8, 6])
    >>> np.ptp(x, axis=0)
    array([2, 0, 5, 2])
    >>> np.ptp(x)
    10

```

```

2125: (4) This example shows that a negative value can be returned when
2126: (4) the input is an array of signed integers.
2127: (4) >>> y = np.array([[1, 127],
2128: (4) ... [0, 127],
2129: (4) ... [-1, 127],
2130: (4) ... [-2, 127]], dtype=np.int8)
2131: (4) >>> np.ptp(y, axis=1)
2132: (4) array([ 126, 127, -128, -127], dtype=int8)
2133: (4) A work-around is to use the `view()` method to view the result as
2134: (4) unsigned integers with the same bit width:
2135: (4) >>> np.ptp(y, axis=1).view(np.uint8)
2136: (4) array([126, 127, 128, 129], dtype=uint8)
2137: (4) """

2154: (0) def max(a, axis=None, out=None, keepdims=np._NoValue, initial=np._NoValue,
2155: (9)           where=np._NoValue):
2156: (4) """
2157: (4)     Return the maximum of an array or maximum along an axis.
2158: (4) Parameters
2159: (4) -----
2160: (4)     a : array_like
2161: (8)         Input data.
2162: (4)     axis : None or int or tuple of ints, optional
2163: (8)         Axis or axes along which to operate. By default, flattened input is
2164: (8)         used.
2165: (8)         .. versionadded:: 1.7.0
2166: (8)         If this is a tuple of ints, the maximum is selected over multiple
2167: (8)         axes,
2168: (4)         instead of a single axis or all the axes as before.
2169: (8)     out : ndarray, optional
2170: (8)         Alternative output array in which to place the result. Must
2171: (8)         be of the same shape and buffer length as the expected output.
2172: (8)         See :ref:`ufuncs-output-type` for more details.
2173: (4)     keepdims : bool, optional
2174: (8)         If this is set to True, the axes which are reduced are left
2175: (8)         in the result as dimensions with size one. With this option,
2176: (8)         the result will broadcast correctly against the input array.
2177: (8)         If the default value is passed, then `keepdims` will not be
2178: (8)         passed through to the ``max`` method of sub-classes of
2179: (8)         `ndarray`, however any non-default value will be. If the
2180: (8)         sub-class' method does not implement `keepdims` any
2181: (4)         exceptions will be raised.
2182: (8)     initial : scalar, optional
2183: (8)         The minimum value of an output element. Must be present to allow
2184: (8)         computation on empty slice. See `~numpy.ufunc.reduce` for details.
2185: (4)         .. versionadded:: 1.15.0
2186: (8)     where : array_like of bool, optional
2187: (8)         Elements to compare for the maximum. See `~numpy.ufunc.reduce`
2188: (8)         for details.
2189: (4)         .. versionadded:: 1.17.0
2190: (4) Returns
2191: (4) -----
2192: (8)     max : ndarray or scalar
2193: (8)         Maximum of `a`. If `axis` is None, the result is a scalar value.

```

```

2193: (8)           If `axis` is an int, the result is an array of dimension
2194: (8)           ``a.ndim - 1``. If `axis` is a tuple, the result is an array of
2195: (8)           dimension ``a.ndim - len(axis)``.
2196: (4)           See Also
2197: (4)
2198: (4)
2199: (8)           amin :
2200: (4)           The minimum value of an array along a given axis, propagating any
2201: (8)           NaNs.
2202: (4)
2203: (8)           nanmax :
2204: (4)           The maximum value of an array along a given axis, ignoring any NaNs.
2205: (8)           maximum :
2206: (4)           Element-wise maximum of two arrays, propagating any NaNs.
2207: (4)           fmax :
2208: (4)           Element-wise maximum of two arrays, ignoring any NaNs.
2209: (4)           argmax :
2210: (4)           Return the indices of the maximum values.
2211: (4)           nanmin, minimum, fmin
2212: (4)           Notes
2213: (4)
2214: (4)           NaN values are propagated, that is if at least one item is NaN, the
2215: (4)           corresponding max value will be NaN as well. To ignore NaN values
2216: (4)           (MATLAB behavior), please use nanmax.
2217: (4)           Don't use `~numpy.max` for element-wise comparison of 2 arrays; when
2218: (4)           ``a.shape[0]`` is 2, ``maximum(a[0], a[1])`` is faster than
2219: (4)           ``max(a, axis=0)``.
2220: (4)           Examples
2221: (4)
2222: (11)
2223: (4)           >>> a = np.arange(4).reshape((2,2))
2224: (4)           >>> a
2225: (4)           array([[0, 1],
2226: (4)           [2, 3]])
2227: (4)           >>> np.max(a)           # Maximum of the flattened array
2228: (4)           3
2229: (4)           >>> np.max(a, axis=0)    # Maxima along the first axis
2230: (4)           array([2, 3])
2231: (4)           >>> np.max(a, axis=1)    # Maxima along the second axis
2232: (4)           array([1, 3])
2233: (4)           >>> np.max(a, where=[False, True], initial=-1, axis=0)
2234: (4)           array([-1, 3])
2235: (4)           >>> b = np.arange(5, dtype=float)
2236: (4)           >>> b[2] = np.NaN
2237: (4)           >>> np.max(b)
2238: (4)           nan
2239: (4)           >>> np.max(b, where=~np.isnan(b), initial=-1)
2240: (4)           4.0
2241: (4)           >>> np.nanmax(b)
2242: (4)           4.0
2243: (4)           You can use an initial value to compute the maximum of an empty slice, or
2244: (4)           to initialize it to a different value:
2245: (4)           >>> np.max([-50], [10]), axis=-1, initial=0)
2246: (4)           array([ 0, 10])
2247: (4)           Notice that the initial value is used as one of the elements for which the
2248: (4)           maximum is determined, unlike for the default argument Python's max
2249: (4)           function, which is only used for empty iterables.
2250: (4)           >>> np.max([5], initial=6)
2251: (4)           6
2252: (26)           >>> max([5], default=6)
2253: (0)           5
2254: (0)           """
2255: (9)           return _wrapreduction(a, np.maximum, 'max', axis, None, out,
2256: (4)           keepdims=keepdims, initial=initial, where=where)
2257: (4)           @array_function_dispatch(_max_dispatcher)
2258: (4)           def amax(a, axis=None, out=None, keepdims=np._NoValue, initial=np._NoValue,
2259: (4)           where=np._NoValue):
2260: (4)           """
2261: (4)           Return the maximum of an array or maximum along an axis.
2262: (4)           `amax` is an alias of `~numpy.max`.

2384: (0) @array_function_dispatch(_prod_dispatcher)
2385: (0) def prod(a, axis=None, dtype=None, out=None, keepdims=np._NoValue,
2386: (9)     initial=np._NoValue, where=np._NoValue):
2387: (4) """
2388: (4)     Return the product of array elements over a given axis.
2389: (4)     Parameters
2390: (4)     -----
2391: (4)     a : array_like
2392: (8)         Input data.
2393: (4)     axis : None or int or tuple of ints, optional
2394: (8)         Axis or axes along which a product is performed. The default,
2395: (8)         axis=None, will calculate the product of all the elements in the
2396: (8)         input array. If axis is negative it counts from the last to the

```

```

2397: (8)           first axis.
2398: (8)           .. versionadded:: 1.7.0
2399: (8)           If axis is a tuple of ints, a product is performed on all of the
2400: (8)           axes specified in the tuple instead of a single axis or all the
2401: (8)           axes as before.
2402: (4)           dtype : dtype, optional
2403: (8)           The type of the returned array, as well as of the accumulator in
2404: (8)           which the elements are multiplied. The dtype of `a` is used by
2405: (8)           default unless `a` has an integer dtype of less precision than the
2406: (8)           default platform integer. In that case, if `a` is signed then the
2407: (8)           platform integer is used while if `a` is unsigned then an unsigned
2408: (8)           integer of the same precision as the platform integer is used.
2409: (4)           out : ndarray, optional
2410: (8)           Alternative output array in which to place the result. It must have
2411: (8)           the same shape as the expected output, but the type of the output
2412: (8)           values will be cast if necessary.

2424: (8)           .. versionadded:: 1.15.0
2425: (4)           where : array_like of bool, optional
2426: (8)           Elements to include in the product. See `~numpy.ufunc.reduce` for
details.
2427: (8)           .. versionadded:: 1.17.0
2428: (4)           Returns
2429: (4)           -----
2430: (4)           product_along_axis : ndarray, see `dtype` parameter above.
2431: (8)           An array shaped as `a` but with the specified axis removed.
2432: (8)           Returns a reference to `out` if specified.
2433: (4)           See Also
2434: (4)           -----
2435: (4)           ndarray.prod : equivalent method
2436: (4)           :ref:`ufuncs-output-type`
2437: (4)           Notes
2438: (4)           -----
2439: (4)           Arithmetic is modular when using integer types, and no error is
2440: (4)           raised on overflow. That means that, on a 32-bit platform:
2441: (4)           >>> x = np.array([536870910, 536870910, 536870910, 536870910])
2442: (4)
2443: (4)           16 # may vary
2444: (4)           The product of an empty array is the neutral element 1:
2445: (4)           >>> np.prod([])
2446: (4)           1.0
2447: (4)           Examples
2448: (4)           -----
2449: (4)           By default, calculate the product of all elements:
2450: (4)           >>> np.prod([1., 2.])
2451: (4)           2.0
2452: (4)           Even when the input array is two-dimensional:
2453: (4)           >>> a = np.array([[1., 2.], [3., 4.]])
2454: (4)           >>> np.prod(a)
2455: (4)           24.0
2456: (4)           But we can also specify the axis over which to multiply:
2457: (4)           >>> np.prod(a, axis=1)
2458: (4)           array([ 2., 12.])
2459: (4)           >>> np.prod(a, axis=0)
2460: (4)           array([3., 8.])
2461: (4)           Or select specific elements to include:
2462: (4)           >>> np.prod([1., np.nan, 3.], where=[True, False, True])
2463: (4)           3.0

```

```

2464: (4)           If the type of `x` is unsigned, then the output type is
2465: (4)           the unsigned platform integer:
2466: (4)           >>> x = np.array([1, 2, 3], dtype=np.uint8)
2467: (4)           >>> np.prod(x).dtype == np.uint
2468: (4)           True
2469: (4)           If `x` is of a signed integer type, then the output type
2470: (4)           is the default platform integer:
2471: (4)           >>> x = np.array([1, 2, 3], dtype=np.int8)
2472: (4)           >>> np.prod(x).dtype == int
2473: (4)           True
2474: (4)           You can also start the product with a value other than one:
2475: (4)           >>> np.prod([1, 2], initial=5)
2476: (4)           10
2477: (4)           """
2478: (4)           return _wrapreduction(a, np.multiply, 'prod', axis, dtype, out,
2479: (26)                 keepdims=keepdims, initial=initial, where=where)
2480: (0)           def _cumprod_dispatcher(a, axis=None, dtype=None, out=None):
2481: (4)               return (a, out)
2482: (0)           @array_function_dispatch(_cumprod_dispatcher)
2483: (0)           def cumprod(a, axis=None, dtype=None, out=None):
2484: (4)               """
2485: (4)               Return the cumulative product of elements along a given axis.
2486: (4)               Parameters
2487: (4)               -----
2488: (4)               a : array_like
2489: (8)                   Input array.
2490: (4)               axis : int, optional
2491: (8)                   Axis along which the cumulative product is computed. By default
2492: (8)                   the input is flattened.
2493: (4)               dtype : dtype, optional
2494: (8)                   Type of the returned array, as well as of the accumulator in which
2495: (8)                   the elements are multiplied. If *dtype* is not specified, it
2496: (8)                   defaults to the dtype of `a`, unless `a` has an integer dtype with
2497: (8)                   a precision less than that of the default platform integer. In
2498: (8)                   that case, the default platform integer is used instead.
2499: (4)               out : ndarray, optional
2500: (8)                   Alternative output array in which to place the result. It must
2501: (8)                   have the same shape and buffer length as the expected output
2502: (8)                   but the type of the resulting values will be cast if necessary.
2503: (4)               Returns
2504: (4)               -----
2505: (4)               cumprod : ndarray
2506: (8)                   A new array holding the result is returned unless `out` is
2507: (8)                   specified, in which case a reference to out is returned.
2508: (4)               See Also
2509: (4)               -----
2510: (4)               :ref:`ufuncs-output-type`

 return asarray(a).shape[axis]

def \_round\_dispatcher(a, decimals=None, out=None):  
 return (a, out)

@array\_function\_dispatch(\_round\_dispatcher)

def round(a, decimals=0, out=None):  
 """  
 Evenly round to the given number of decimals.  
 Parameters  
 -----  
 a : array\_like  
 Input data.  
 decimals : int, optional  
 Number of decimal places to round to (default: 0). If  
 decimals is negative, it specifies the number of positions to  
 the left of the decimal point.  
 out : ndarray, optional  
 Alternative output array in which to place the result. It must have  
 the same shape as the expected output, but the type of the output  
 values will be cast if necessary. See :ref:`ufuncs-output-type` for  
 more  
 details.  
 Returns  
 -----  
 rounded\_array : ndarray  
 An array of the same type as `a`, containing the rounded values.  
 Unless `out` was specified, a new array is created. A reference to  
 the result is returned.  
 The real and imaginary parts of complex numbers are rounded  
 separately. The result of rounding a float is a float.  
 See Also  
 -----  
 ndarray.round : equivalent method  
 around : an alias for this function  
 ceil, fix, floor, rint, trunc  
 Notes  
 -----  
 For values exactly halfway between rounded decimal values, NumPy  
 rounds to the nearest even value. Thus 1.5 and 2.5 round to 2.0,  
 -0.5 and 0.5 round to 0.0, etc.  
 ``np.round`` uses a fast but sometimes inexact algorithm to round  
 floating-point datatypes. For positive `decimals` it is equivalent to  
 ``np.true\_divide(np.rint(a \* 10\*\*decimals), 10\*\*decimals)``  
 , which has  
 error due to the inexact representation of decimal fractions in the IEEE  
 floating point standard [1]\_ and errors introduced when scaling by powers  
 of ten. For instance, note the extra "1" in the following:  
 >>> np.round(56294995342131.5, 3)  
 56294995342131.51  
 If your goal is to print such values with a fixed number of decimals, it  
 is  
 preferable to use numpy's float printing routines to limit the number of  
 printed decimals:  
 >>> np.format\_float\_positional(56294995342131.5, precision=3)  
 '56294995342131.5'  
 The float printing routines use an accurate but much more computationally  
 demanding algorithm to compute the number of digits after the decimal  
 point.  
 Alternatively, Python's builtin `round` function uses a more accurate  
 but slower algorithm for 64-bit floating point values:  
 >>> round(56294995342131.5, 3)  
 56294995342131.5  
 >>> np.round(16.055, 2), round(16.055, 2) # equals  
 (16.06, 16.05)

```

def mean(a, axis=None, dtype=None, out=None, keepdims=np._NoValue, *, where=np._NoValue):
    """
    Compute the arithmetic mean along the specified axis.
    Returns the average of the array elements. The average is taken over
    the flattened array by default, otherwise over the specified axis.
    `float64` intermediate and return values are used for integer inputs.
    Parameters
    -----
    a : array_like
        Array containing numbers whose mean is desired. If `a` is not an
        array, a conversion is attempted.
    axis : None or int or tuple of ints, optional
        Axis or axes along which the means are computed. The default is to
        compute the mean of the flattened array.
        .. versionadded:: 1.7.0
        If this is a tuple of ints, a mean is performed over multiple axes,
        instead of a single axis or all the axes as before.
    dtype : data-type, optional
        Type to use in computing the mean. For integer inputs, the default
        is `float64`; for floating point inputs, it is the same as the
        input dtype.

        Alternate output array in which to place the result. The default
        is ``None``; if provided, it must have the same shape as the
        expected output, but the type will be cast if necessary.
        See :ref:`ufuncs-output-type` for more details.
    keepdims : bool, optional
        If this is set to True, the axes which are reduced are left
        in the result as dimensions with size one. With this option,
        the result will broadcast correctly against the input array.
        If the default value is passed, then `keepdims` will not be
        passed through to the `mean` method of sub-classes of
        `ndarray`, however any non-default value will be. If the
        sub-class' method does not implement `keepdims` any

```

```

2737: (8)             exceptions will be raised.
2738: (4)             where : array_like of bool, optional
2739: (8)                 Elements to include in the mean. See `~numpy.ufunc.reduce` for
details.
2740: (8)                 .. versionadded:: 1.20.0
2741: (4)             Returns
2742: (4)             -----
2743: (4)             m : ndarray, see dtype parameter above
2744: (8)                 If `out=None`, returns a new array containing the mean values,
2745: (8)                 otherwise a reference to the output array is returned.
2746: (4)             See Also
2747: (4)             -----
2748: (4)             average : Weighted average
2749: (4)             std, var, nanmean, nanstd, nanvar
2750: (4)             Notes
2751: (4)             -----
2752: (4)                 The arithmetic mean is the sum of the elements along the axis divided
2753: (4)                 by the number of elements.
2754: (4)                 Note that for floating-point input, the mean is computed using the
2755: (4)                 same precision the input has. Depending on the input data, this can
2756: (4)                 cause the results to be inaccurate, especially for `float32` (see
2757: (4)                 example below). Specifying a higher-precision accumulator using the
2758: (4)                 `dtype` keyword can alleviate this issue.
2759: (4)                 By default, `float16` results are computed using `float32` intermediates
2760: (4)                 for extra precision.
2761: (4)             Examples
2762: (4)             -----
2763: (4)             >>> a = np.array([[1, 2], [3, 4]])
2764: (4)             >>> np.mean(a)
2765: (4)             2.5
2766: (4)             >>> np.mean(a, axis=0)
2767: (4)             array([2., 3.])
2768: (4)             >>> np.mean(a, axis=1)
2769: (4)             array([1.5, 3.5])
2770: (4)             In single precision, `mean` can be inaccurate:
2771: (4)             >>> a = np.zeros((2, 512*512), dtype=np.float32)
2772: (4)             >>> a[0, :] = 1.0
2773: (4)             >>> a[1, :] = 0.1
2774: (4)             >>> np.mean(a)
2775: (4)             0.54999924
2776: (4)             Computing the mean in float64 is more accurate:
2777: (4)             >>> np.mean(a, dtype=np.float64)
2778: (4)             0.55000000074505806 # may vary
2779: (4)             Specifying a where argument:
2780: (4)             >>> a = np.array([[5, 9, 13], [14, 10, 12], [11, 15, 19]])
2781: (4)             >>> np.mean(a)
2782: (4)             12.0
2783: (4)             >>> np.mean(a, where=[[True], [False], [False]])
2784: (4)             9.0
2785: (4)             """
2786: (4)             kwargs = {}
2787: (4)             if keepdims is not np._NoValue:
2788: (8)                 kwargs['keepdims'] = keepdims
2789: (4)             if where is not np._NoValue:
2790: (8)                 kwargs['where'] = where

2821: (4)           dtype : dtype, optional
2822: (8)           Type to use in computing the standard deviation. For arrays of
2823: (8)           integer type the default is float64, for arrays of float types it is
2824: (8)           the same as the array type.
2825: (4)           out : ndarray, optional
2826: (8)           Alternative output array in which to place the result. It must have
2827: (8)           the same shape as the expected output but the type (of the calculated
2828: (8)           values) will be cast if necessary.
2829: (4)           ddof : int, optional
2830: (8)           Means Delta Degrees of Freedom. The divisor used in calculations
2831: (8)           is ``N - ddof``, where ``N`` represents the number of elements.
2832: (8)           By default `ddof` is zero.
2833: (4)           keepdims : bool, optional
2834: (8)           If this is set to True, the axes which are reduced are left
2835: (8)           in the result as dimensions with size one. With this option,
2836: (8)           the result will broadcast correctly against the input array.
2837: (8)           If the default value is passed, then `keepdims` will not be
2838: (8)           passed through to the `std` method of sub-classes of
2839: (8)           `ndarray`, however any non-default value will be. If the
2840: (8)           sub-class' method does not implement `keepdims` any
2841: (8)           exceptions will be raised.
2842: (4)           where : array_like of bool, optional
2843: (8)           Elements to include in the standard deviation.
2844: (8)           See `~numpy.ufunc.reduce` for details.
2845: (8)           .. versionadded:: 1.20.0
2846: (4)           Returns
2847: (4)           -----
2848: (4)           standard_deviation : ndarray, see dtype parameter above.
2849: (8)           If `out` is None, return a new array containing the standard
2850: (8)           otherwise return a reference to the output array.
2851: (4)           See Also
2852: (4)           -----
2853: (4)           var, mean, nanmean, nanstd, nanvar
2854: (4)           :ref:`ufuncs-output-type`
2855: (4)           Notes
2856: (4)           -----
2857: (4)           The standard deviation is the square root of the average of the squared
2858: (4)           deviations from the mean, i.e., ``std = sqrt(mean(x))``, where
2859: (4)           ``x = abs(a - a.mean())**2``.
2860: (4)           The average squared deviation is typically calculated as ``x.sum() / N``,
2861: (4)           where ``N = len(x)``. If, however, `ddof` is specified, the divisor
2862: (4)           ``N - ddof`` is used instead. In standard statistical practice, ``ddof=1``
2863: (4)           provides an unbiased estimator of the variance of the infinite population.
2864: (4)           ``ddof=0`` provides a maximum likelihood estimate of the variance for
2865: (4)           normally distributed variables. The standard deviation computed in this
2866: (4)           function is the square root of the estimated variance, so even with
2867: (4)           ``ddof=1``, it will not be an unbiased estimate of the standard deviation
2868: (4)           per se.
2869: (4)           Note that, for complex numbers, `std` takes the absolute
2870: (4)           value before squaring, so that the result is always real and nonnegative.
2871: (4)           For floating-point input, the *std* is computed using the same
2872: (4)           precision the input has. Depending on the input data, this can cause

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

2873: (4)          the results to be inaccurate, especially for float32 (see example below).
2874: (4)          Specifying a higher-accuracy accumulator using the `dtype` keyword can
2875: (4)          alleviate this issue.
2876: (4)          Examples
2877: (4)          -----
2878: (4)          >>> a = np.array([[1, 2], [3, 4]])
2879: (4)          >>> np.std(a)
2880: (4)          1.1180339887498949 # may vary
2881: (4)          >>> np.std(a, axis=0)
2882: (4)          array([1., 1.])
2883: (4)          >>> np.std(a, axis=1)
2884: (4)          array([0.5, 0.5])
2885: (4)          In single precision, std() can be inaccurate:
2886: (4)          >>> a = np.zeros((2, 512*512), dtype=np.float32)
2887: (4)          >>> a[0, :] = 1.0
2888: (4)          >>> a[1, :] = 0.1
2889: (4)          >>> np.std(a)
2890: (4)          0.45000005
2891: (4)          Computing the standard deviation in float64 is more accurate:
2892: (4)          >>> np.std(a, dtype=np.float64)
2893: (4)          0.44999999925494177 # may vary
2894: (4)          Specifying a where argument:
2895: (4)          >>> a = np.array([[14, 8, 11, 10], [7, 9, 10, 11], [10, 15, 5, 10]])
2896: (4)          >>> np.std(a)
2897: (4)          2.614064523559687 # may vary
2898: (4)          >>> np.std(a, where=[[True], [True], [False]])
2899: (4)          2.0
2900: (4)          """
2901: (4)          kwargs = {}
2902: (4)          if keepdims is not np._NoValue:
2903: (8)              kwargs['keepdims'] = keepdims
2904: (4)          if where is not np._NoValue:
2905: (8)              kwargs['where'] = where
2906: (4)          if type(a) is not mu.ndarray:
2907: (8)              try:
2908: (12)                  std = a.std
2909: (8)              except AttributeError:
2910: (12)                  pass
2911: (8)              else:
2912: (12)                  return std(axis=axis, dtype=dtype, out=out, ddof=ddof, **kwargs)
2913: (4)          return _methods._std(a, axis=axis, dtype=dtype, out=out, ddof=ddof,
2914: (25)                      **kwargs)
2915: (0)          def _var_dispatcher(a, axis=None, dtype=None, out=None, ddof=None,
2916: (20)                      keepdims=None, *, where=None):
2917: (4)              return (a, where, out)
2918: (0)          @array_function_dispatch(_var_dispatcher)
2919: (0)          def var(a, axis=None, dtype=None, out=None, ddof=0, keepdims=np._NoValue, *,
2920: (8)                      where=np._NoValue):
2921: (4)                      """
2922: (4)              Compute the variance along the specified axis.
2923: (4)              Returns the variance of the array elements, a measure of the spread of a
2924: (4)              distribution. The variance is computed for the flattened array by
2925: (4)              default, otherwise over the specified axis.
2926: (4)          Parameters
2927: (4)          -----
2928: (4)          a : array_like
2929: (8)              Array containing numbers whose variance is desired. If `a` is not an
2930: (8)              array, a conversion is attempted.
2931: (4)          axis : None or int or tuple of ints, optional
2932: (8)              Axis or axes along which the variance is computed. The default is to
2933: (8)              compute the variance of the flattened array.
2934: (8)              .. versionadded:: 1.7.0
2935: (8)              If this is a tuple of ints, a variance is performed over multiple
2936: (8)              axes,
2937: (4)              instead of a single axis or all the axes as before.
2938: (8)          dtype : data-type, optional
2939: (8)              Type to use in computing the variance. For arrays of integer type
2940: (8)              the default is `float64`; for arrays of float types it is the same as

```

```

2941: (4)          out : ndarray, optional
2942: (8)            Alternate output array in which to place the result. It must have
2943: (8)            the same shape as the expected output, but the type is cast if
2944: (8)            necessary.
2945: (4)          ddof : int, optional
2946: (8)            "Delta Degrees of Freedom": the divisor used in the calculation is
2947: (8)            ``N - ddof``, where ``N`` represents the number of elements. By
2948: (8)            default `ddof` is zero.
2949: (4)          keepdims : bool, optional
2950: (8)            If this is set to True, the axes which are reduced are left
2951: (8)            in the result as dimensions with size one. With this option,
2952: (8)            the result will broadcast correctly against the input array.
2953: (8)            If the default value is passed, then `keepdims` will not be
2954: (8)            passed through to the `var` method of sub-classes of
2955: (8)            `ndarray`, however any non-default value will be. If the
2956: (8)            sub-class' method does not implement `keepdims` any
2957: (8)            exceptions will be raised.
2958: (4)          where : array_like of bool, optional
2959: (8)            Elements to include in the variance. See `~numpy.ufunc.reduce` for
2960: (8)            details.
2961: (8)            .. versionadded:: 1.20.0
2962: (4)          Returns
2963: (4)          -----
2964: (4)          variance : ndarray, see dtype parameter above
2965: (8)            If ``out=None``, returns a new array containing the variance;
2966: (8)            otherwise, a reference to the output array is returned.
2967: (4)          See Also
2968: (4)          -----
2969: (4)          std, mean, nanmean, nanstd, nanvar
2970: (4)          :ref:`ufuncs-output-type`
2971: (4)          Notes
2972: (4)          -----
2973: (4)          The variance is the average of the squared deviations from the mean,
2974: (4)          i.e., ``var = mean(x)**2``. where ``x = abs(a - a.mean())**2``.
2975: (4)          The mean is typically calculated as ``x.sum() / N``, where ``N = len(x)``.
2976: (4)          If, however, `ddof` is specified, the divisor ``N - ddof`` is used
2977: (4)          instead. In standard statistical practice, ``ddof=1`` provides an
2978: (4)          unbiased estimator of the variance of a hypothetical infinite population.
2979: (4)          ``ddof=0`` provides a maximum likelihood estimate of the variance for
2980: (4)          normally distributed variables.
2981: (4)          Note that for complex numbers, the absolute value is taken before
2982: (4)          squaring, so that the result is always real and nonnegative.
2983: (4)          For floating-point input, the variance is computed using the same
2984: (4)          precision the input has. Depending on the input data, this can cause
2985: (4)          the results to be inaccurate, especially for `float32` (see example
2986: (4)          below). Specifying a higher-accuracy accumulator using the ``dtype``
2987: (4)          keyword can alleviate this issue.
2988: (4)          Examples
2989: (4)          -----
2990: (4)          >>> a = np.array([[1, 2], [3, 4]])
2991: (4)          >>> np.var(a)
2992: (4)          1.25
2993: (4)          >>> np.var(a, axis=0)
2994: (4)          array([1., 1.])
2995: (4)          >>> np.var(a, axis=1)
2996: (4)          array([0.25, 0.25])
2997: (4)          In single precision, var() can be inaccurate:
2998: (4)          >>> a = np.zeros((2, 512*512), dtype=np.float32)
2999: (4)          >>> a[0, :] = 1.0
3000: (4)          >>> a[1, :] = 0.1
3001: (4)          >>> np.var(a)
3002: (4)          0.20250003
3003: (4)          Computing the variance in float64 is more accurate:
3004: (4)          >>> np.var(a, dtype=np.float64)
3005: (4)          0.20249999932944759 # may vary
3006: (4)          >>> ((1-0.55)**2 + (0.1-0.55)**2)/2
3007: (4)          0.2025
3008: (4)          Specifying a where argument:
3009: (4)          >>> a = np.array([[14, 8, 11, 10], [7, 9, 10, 11], [10, 15, 5, 10]])

```

24: (4) .. versionchanged:: 1.16.0
25: (8)     Non-scalar `start` and `stop` are now supported.
26: (4) .. versionchanged:: 1.20.0
27: (8)     Values are rounded towards ``-inf`` instead of ``0`` when an
28: (8)     integer ``dtype`` is specified. The old behavior can
29: (8)     still be obtained with ``np.linspace(start, stop, num).astype(int)``
30: (4) Parameters
31: (4) -----
32: (4) start : array_like
33: (8)     The starting value of the sequence.
34: (4) stop : array_like
35: (8)     The end value of the sequence, unless `endpoint` is set to False.
36: (8)     In that case, the sequence consists of all but the last of ``num + 1``
37: (8)     evenly spaced samples, so that `stop` is excluded. Note that the step
38: (8)     size changes when `endpoint` is False.
39: (4) num : int, optional
40: (8)     Number of samples to generate. Default is 50. Must be non-negative.
41: (4) endpoint : bool, optional
42: (8)     If True, `stop` is the last sample. Otherwise, it is not included.
43: (8)     Default is True.
44: (4) retstep : bool, optional
45: (8)     If True, return ('samples', 'step'), where `step` is the spacing
46: (8)     between samples.
47: (4) dtype : dtype, optional
48: (8)     The type of the output array. If `dtype` is not given, the data type
49: (8)     is inferred from `start` and `stop`. The inferred dtype will never be
50: (8)     an integer; 'float' is chosen even if the arguments would produce an
51: (8)     array of integers.
52: (8)     .. versionadded:: 1.9.0
53: (4) axis : int, optional
54: (8)     The axis in the result to store the samples. Relevant only if start
55: (8)     or stop are array-like. By default (0), the samples will be along a
56: (8)     new axis inserted at the beginning. Use -1 to get an axis at the end.
57: (8)     .. versionadded:: 1.16.0
58: (4) Returns
59: (4) -----
60: (4) samples : ndarray
61: (8)     There are `num` equally spaced samples in the closed interval
62: (8)     ``[start, stop]`` or the half-open interval ``[start, stop)``
63: (8)     (depending on whether `endpoint` is True or False).
64: (4) step : float, optional
65: (8)     Only returned if `retstep` is True
66: (8)     Size of spacing between samples.
67: (4) See Also
68: (4) -----
69: (4) arange : Similar to 'linspace', but uses a step size (instead of the
70: (13)     number of samples).
71: (4) geomspace : Similar to 'linspace', but with numbers spaced evenly on a log
72: (16)     scale (a geometric progression).
73: (4) logspace : Similar to 'geomspace', but with the end points specified as
74: (15)     logarithms.
75: (4) :ref:`how-to-partition`
76: (4) Examples
77: (4) -----
78: (4) >>> np.linspace(2.0, 3.0, num=5)

        Return numbers spaced evenly on a log scale (a geometric progression).
        This is similar to `logspace`, but with endpoints specified directly.
        Each output sample is a constant multiple of the previous.
        .. versionchanged:: 1.16.0
            Non-scalar `start` and `stop` are now supported.

        Parameters
        -----
        start : array_like
            The starting value of the sequence.
        stop : array_like
            The final value of the sequence, unless `endpoint` is False.
            In that case, ``num + 1`` values are spaced over the
            interval in log-space, of which all but the last (a sequence of
            length `num`) are returned.
        num : integer, optional
            Number of samples to generate. Default is 50.
        endpoint : boolean, optional
            If true, `stop` is the last sample. Otherwise, it is not included.
            Default is True.
        dtype : dtype
            The type of the output array. If `dtype` is not given, the data type
            is inferred from `start` and `stop`. The inferred dtype will never be
            an integer; `float` is chosen even if the arguments would produce an
            array of integers.
        axis : int, optional
            The axis in the result to store the samples. Relevant only if start
            or stop are array-like. By default (0), the samples will be along a
            new axis inserted at the beginning. Use -1 to get an axis at the end.
            .. versionadded:: 1.16.0

        Returns
        -----
        samples : ndarray
            `num` samples, equally spaced on a log scale.

        See Also
        -----
        logspace : Similar to geomspace, but with endpoints specified using log
                   and base.
        linspace : Similar to geomspace, but with arithmetic instead of geometric
                   progression.
        arange : Similar to linspace, with the step size specified instead of the
                 number of samples.
        :ref:`how-to-partition`

        Notes
        -----
        If the inputs or dtype are complex, the output will follow a logarithmic
        spiral in the complex plane. (There are an infinite number of spirals
        passing through two points; the output will follow the shortest such
        path.)

        Examples
        -----
        >>> np.geomspace(1, 1000, num=4)
        array([ 1.,   10.,  100., 1000.])

405: (8)                 If a string, the documentation to apply to `obj`
406: (8)                 If a tuple, then the first element is interpreted as an attribute of
407: (8)                 `obj` and the second as the docstring to apply - ``(method,
docstring)``
408: (8)                 If a list, then each element of the list should be a tuple of length
409: (8)                   two - ``[(method1, docstring1), (method2, docstring2), ...]``
410: (4)               warn_on_python : bool
411: (8)                 If True, the default, emit `UserWarning` if this is used to attach
412: (8)                   documentation to a pure-python object.
413: (4)               Notes
414: (4)               -----
415: (4)                 This routine never raises an error if the docstring can't be written, but
416: (4)                 will raise an error if the object being documented does not exist.
417: (4)                 This routine cannot modify read-only docstrings, as appear
418: (4)                 in new-style classes or built-in functions. Because this
419: (4)                 routine never raises an error the caller must check manually
420: (4)                 that the docstrings were changed.
421: (4)                 Since this function grabs the ``char *`` from a c-level str object and
puts
422: (4)                   it into the ``tp_doc`` slot of the type of `obj`, it violates a number of
423: (4)                   C-API best-practices, by:
424: (4)                     - modifying a `PyTypeObject` after calling `PyType_Ready`
425: (4)                     - calling `Py_INCREF` on the str and losing the reference, so the str
426: (6)                       will never be released
427: (4)                     If possible it should be avoided.
428: (4)                     """

358: (4)           Notes
359: (4)           -----
360: (4)             For developers of NumPy: do not instantiate this at the module level.
361: (4)             The initial calculation of these parameters is expensive and negatively
362: (4)               impacts import times. These objects are cached, so calling ``finfo()``
363: (4)               repeatedly inside your functions is not a problem.
364: (4)             Note that ``smallest_normal`` is not actually the smallest positive
365: (4)               representable value in a NumPy floating point type. As in the IEEE-754
366: (4)               standard [1]_, NumPy floating point types make use of subnormal numbers to
367: (4)               fill the gap between 0 and ``smallest_normal``. However, subnormal numbers
368: (4)               may have significantly reduced precision [2]_.
369: (4)             This function can also be used for complex data types as well. If used,
370: (4)               the output will be the same as the corresponding real float type
371: (4)                 (e.g. numpy.finfo(numpy.csingle) is the same as
numpy.finfo(numpy.single)).
372: (4)               However, the output is true for the real and imaginary components.

14: (4)     "write": "w"
15: (4) }
16: (0) @set_module('numpy')
17: (0) class memmap(ndarray):
18: (4)     """Create a memory-map to an array stored in a *binary* file on disk.
19: (4)     Memory-mapped files are used for accessing small segments of large files
20: (4)     on disk, without reading the entire file into memory. NumPy's
21: (4)     memmap's are array-like objects. This differs from Python's ``mmap``
22: (4)     module, which uses file-like objects.
23: (4)     This subclass of ndarray has some unpleasant interactions with
24: (4)     some operations, because it doesn't quite fit properly as a subclass.
25: (4)     An alternative to using this subclass is to create the ``mmap``
26: (4)     object yourself, then create an ndarray with ndarray.__new__ directly,
27: (4)     passing the object created in its 'buffer=' parameter.
28: (4)     This class may at some point be turned into a factory function
29: (4)     which returns a view into an mmap buffer.
30: (4)     Flush the memmap instance to write the changes to the file. Currently
there
31: (4)     is no API to close the underlying ``mmap``. It is tricky to ensure the
32: (4)     resource is actually closed, since it may be shared between different
33: (4)     memmap instances.
34: (4)     Parameters
35: (4)     -----
36: (4)     filename : str, file-like object, or pathlib.Path instance
37: (8)         The file name or file object to be used as the array data buffer.
38: (4)     dtype : data-type, optional
39: (8)         The data-type used to interpret the file contents.
40: (8)         Default is `uint8`.
41: (4)     mode : {'r+', 'r', 'w+', 'c'}, optional
42: (8)         The file is opened in this mode:
43: (8)         +-----+
44: (8)         | 'r' | Open existing file for reading only.
45: (8)         +-----+
46: (8)         | 'r+' | Open existing file for reading and writing.
47: (8)         +-----+
48: (8)         | 'w+' | Create or overwrite existing file for reading and writing.
49: (8)             | If ``mode == 'w+'`` then `shape` must also be specified.
50: (8)         +-----+
51: (8)         | 'c' | Copy-on-write: assignments affect data in memory, but
52: (8)             | changes are not saved to disk. The file on disk is
53: (8)             | read-only.
54: (8)         +-----+
55: (8)         Default is 'r+'.
56: (4)     offset : int, optional
57: (8)         In the file, array data starts at this offset. Since `offset` is
58: (8)         measured in bytes, it should normally be a multiple of the byte-size
59: (8)         of `dtype`. When ``mode != 'r'``, even positive offsets beyond end of
60: (8)         file are valid; The file will be extended to accommodate the
61: (8)         additional data. By default, ``memmap`` will start at the beginning of
62: (8)         the file, even if ``filename`` is a file pointer ``fp`` and
63: (8)             ``fp.tell() != 0``.
64: (4)     shape : tuple, optional
65: (8)         The desired shape of the array. If ``mode == 'r'`` and the number
66: (8)         of remaining bytes after `offset` is not a multiple of the byte-size
67: (8)         of `dtype`, you must specify `shape`. By default, the returned array
68: (8)         will be 1-D with the number of elements determined by file size
69: (8)         and data-type.
70: (4)     order : {'C', 'F'}, optional

```

```
71: (8)          Specify the order of the ndarray memory layout:
72: (8)          :term:`row-major`, C-style or :term:`column-major`,
73: (8)          Fortran-style. This only has an effect if the shape is
74: (8)          greater than 1-D. The default order is 'C'.
75: (4)          Attributes
76: (4)          -----
77: (4)          filename : str or pathlib.Path instance
78: (8)          Path to the mapped file.
79: (4)          offset : int
80: (8)          Offset position in the file.
81: (4)          mode : str
82: (8)          File mode.
83: (4)          Methods
84: (4)          -----
85: (4)          flush
86: (8)          Flush any changes in memory to file on disk.
87: (8)          When you delete a memmap object, flush is called first to write
88: (8)          changes to disk.
89: (4)          See also
90: (4)          -----
91: (4)          lib.format.open_memmap : Create or load a memory-mapped ``.npy`` file.
92: (4)          Notes
93: (4)          -----
94: (4)          The memmap object can be used anywhere an ndarray is accepted.
95: (4)          Given a memmap ``fp``, ``isinstance(fp, numpy.ndarray)`` returns
96: (4)          ``True``.
97: (4)          Memory-mapped files cannot be larger than 2GB on 32-bit systems.
98: (4)          When a memmap causes a file to be created or extended beyond its
99: (4)          current size in the filesystem, the contents of the new part are
100: (4)          unspecified. On systems with POSIX filesystem semantics, the extended
101: (4)          part will be filled with zero bytes.
102: (4)          Examples
103: (4)          -----
104: (4)          >>> data = np.arange(12, dtype='float32')
105: (4)          >>> data.resize((3,4))
106: (4)          This example uses a temporary file so that doctest doesn't write
107: (4)          files to your directory. You would use a 'normal' filename.
108: (4)          >>> from tempfile import mkdtemp
109: (4)          >>> import os.path as path
110: (4)          >>> filename = path.join(mkdtemp(), 'newfile.dat')
111: (4)          Create a memmap with dtype and shape that matches our data:
112: (4)          >>> fp = np.memmap(filename, dtype='float32', mode='w+', shape=(3,4))
113: (4)          >>> fp
114: (4)          memmap([[0., 0., 0., 0.],
115: (12)            [0., 0., 0., 0.],
116: (12)            [0., 0., 0., 0.]], dtype=float32)
117: (4)          Write data to memmap array:
118: (4)          >>> fp[:] = data[:]
119: (4)          >>> fp
120: (4)          memmap([[ 0.,   1.,   2.,   3.],
121: (12)            [ 4.,   5.,   6.,   7.],
122: (12)            [ 8.,   9.,  10.,  11.]], dtype=float32)
123: (4)          >>> fp.filename == path.abspath(filename)
124: (4)          True
125: (4)          Flushes memory changes to disk in order to read them back
126: (4)          >>> fp.flush()
127: (4)          Load the memmap and verify data was stored:
128: (4)          >>> newfp = np.memmap(filename, dtype='float32', mode='r', shape=(3,4))
129: (4)          >>> newfp
130: (4)          memmap([[ 0.,   1.,   2.,   3.],
131: (12)            [ 4.,   5.,   6.,   7.],
132: (12)            [ 8.,   9.,  10.,  11.]], dtype=float32)
133: (4)          Read-only memmap:
134: (4)          >>> fpr = np.memmap(filename, dtype='float32', mode='r', shape=(3,4))
135: (4)          >>> fpr.flags.writeable
136: (4)          False
137: (4)          Copy-on-write memmap:
138: (4)          >>> fpc = np.memmap(filename, dtype='float32', mode='c', shape=(3,4))
139: (4)          >>> fpc.flags.writeable
```

```

140: (4)           True
141: (4)           It's possible to assign to copy-on-write array, but values are only
142: (4)           written into the memory copy of the array, and not written to disk:
143: (4)
144: (4)           >>> fpc
145: (12)          memmap([[ 0.,  1.,  2.,  3.],
146: (12)          [ 4.,  5.,  6.,  7.],
147: (12)          [ 8.,  9., 10., 11.]], dtype=float32)
148: (4)           >>> fpc[0,:] = 0
149: (4)           >>> fpc
150: (12)          memmap([[ 0.,  0.,  0.,  0.],
151: (12)          [ 4.,  5.,  6.,  7.],
152: (12)          [ 8.,  9., 10., 11.]], dtype=float32)
153: (4)           File on disk is unchanged:
154: (4)           >>> fpr
155: (12)          memmap([[ 0.,  1.,  2.,  3.],
156: (12)          [ 4.,  5.,  6.,  7.],
157: (12)          [ 8.,  9., 10., 11.]], dtype=float32)
158: (4)           Offset into a memmap:
159: (4)           >>> fpo = np.memmap(filename, dtype='float32', mode='r', offset=16)
160: (4)           >>> fpo
161: (4)           memmap([ 4.,  5.,  6.,  7.,  8.,  9., 10., 11.], dtype=float32)
162: (4)           """

72: (4)             empty_like(prototype, dtype=None, order='K', subok=True, shape=None)
73: (4)             Return a new array with the same shape and type as a given array.

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

74: (4)   Parameters
75: (4)   -----
76: (4)   prototype : array_like
77: (8)   The shape and data-type of `prototype` define these same attributes
78: (8)   of the returned array.
79: (4)   dtype : data-type, optional
80: (8)   Overrides the data type of the result.
81: (8)   .. versionadded:: 1.6.0
82: (4)   order : {'C', 'F', 'A', or 'K'}, optional
83: (8)   Overrides the memory layout of the result. 'C' means C-order,
84: (8)   'F' means F-order, 'A' means 'F' if `prototype` is Fortran
85: (8)   contiguous, 'C' otherwise. 'K' means match the layout of `prototype`
86: (8)   as closely as possible.
87: (8)   .. versionadded:: 1.6.0
88: (4)   subok : bool, optional.
89: (8)   If True, then the newly created array will use the sub-class
90: (8)   type of `prototype`, otherwise it will be a base-class array. Defaults
91: (8)   to True.
92: (4)   shape : int or sequence of ints, optional.
93: (8)   Overrides the shape of the result. If order='K' and the number of
94: (8)   dimensions is unchanged, will try to keep order, otherwise,
95: (8)   order='C' is implied.
96: (8)   .. versionadded:: 1.17.0
97: (4)   Returns
98: (4)   -----
99: (4)   out : ndarray
100: (8)   Array of uninitialized (arbitrary) data with the same
101: (8)   shape and type as `prototype`.
102: (4)   See Also
103: (4)   -----
104: (4)   ones_like : Return an array of ones with shape and type of input.
105: (4)   zeros_like : Return an array of zeros with shape and type of input.
106: (4)   full_like : Return a new array with shape of input filled with value.
107: (4)   empty : Return a new uninitialized array.
108: (4)   Notes
109: (4)   -----
110: (4)   This function does *not* initialize the returned array; to do that use
111: (4)   `zeros_like` or `ones_like` instead. It may be marginally faster than
112: (4)   the functions that do set the array values.
113: (4)   Examples
114: (4)   -----
115: (4)   >>> a = ([1,2,3], [4,5,6])                                     # a is array-like
116: (4)
117: (4)   >>> np.empty_like(a)
118: (11)   array([[-1073741821, -1073741821, 3],      # uninitialized
119: (4)   [ 0, 0, -1073741821]])
120: (4)
121: (4)   >>> a = np.array([[1., 2., 3.],[4., 5., 6.]])
122: (11)   >>> np.empty_like(a)
123: (4)   array([[ -2.00000715e+000,  1.48219694e-323, -2.00000572e+000], #
124: (4)   [ 4.38791518e-305, -2.00000715e+000,  4.17269252e-309]])
125: (0)   """
126: (0)   return (prototype,)
127: (4)   @array_function_from_c_func_and_dispatcher(_multiarray_umath.concatenate)
128: (4)   def concatenate(arrays, axis=None, out=None, *, dtype=None, casting=None):
129: (4)   """
130: (4)   concatenate((a1, a2, ...), axis=0, out=None, dtype=None,
131: (4)   Join a sequence of arrays along an existing axis.
132: (4)   Parameters
133: (8)   -----
134: (8)   a1, a2, ... : sequence of array_like
135: (8)   The arrays must have the same shape, except in the dimension
136: (8)   corresponding to `axis` (the first, by default).
137: (8)   axis : int, optional
138: (8)   The axis along which the arrays will be joined. If axis is None,
139: (8)   arrays are flattened before use. Default is 0.
140: (8)   out : ndarray, optional
141: (8)   If provided, the destination to place the result. The shape must be
142: (8)   correct, matching that of what concatenate would have returned if no

```

```

141: (8)          out argument were specified.
142: (4)          dtype : str or dtype
143: (8)            If provided, the destination array will have this dtype. Cannot be
144: (8)            provided together with `out`.
145: (8)            .. versionadded:: 1.20.0
146: (4)          casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
147: (8)            Controls what kind of data casting may occur. Defaults to 'same_kind'.
148: (8)            .. versionadded:: 1.20.0
149: (4)          Returns
150: (4)          -----
151: (4)          res : ndarray
152: (8)            The concatenated array.
153: (4)          See Also
154: (4)          -----
155: (4)          ma.concatenate : Concatenate function that preserves input masks.
156: (4)          array_split : Split an array into multiple sub-arrays of equal or
157: (18)            near-equal size.
158: (4)          split : Split array into a list of multiple sub-arrays of equal size.
159: (4)          hsplit : Split array into multiple sub-arrays horizontally (column wise).
160: (4)          vsplit : Split array into multiple sub-arrays vertically (row wise).
161: (4)          dsplit : Split array into multiple sub-arrays along the 3rd axis (depth).
162: (4)          stack : Stack a sequence of arrays along a new axis.
163: (4)          block : Assemble arrays from blocks.
164: (4)          hstack : Stack arrays in sequence horizontally (column wise).
165: (4)          vstack : Stack arrays in sequence vertically (row wise).
166: (4)          dstack : Stack arrays in sequence depth wise (along third dimension).
167: (4)          column_stack : Stack 1-D arrays as columns into a 2-D array.
168: (4)          Notes
169: (4)          -----
170: (4)          When one or more of the arrays to be concatenated is a MaskedArray,
171: (4)          this function will return a MaskedArray object instead of an ndarray,
172: (4)          but the input masks are *not* preserved. In cases where a MaskedArray
173: (4)          is expected as input, use the ma.concatenate function from the masked
174: (4)          array module instead.
175: (4)          Examples
176: (4)          -----
177: (4)          >>> a = np.array([[1, 2], [3, 4]])
178: (4)          >>> b = np.array([[5, 6]])
179: (4)          >>> np.concatenate((a, b), axis=0)
180: (4)          array([[1, 2],
181: (11)            [3, 4],
182: (11)            [5, 6]])
183: (4)          >>> np.concatenate((a, b.T), axis=1)
184: (4)          array([[1, 2, 5],
185: (11)            [3, 4, 6]])
186: (4)          >>> np.concatenate((a, b), axis=None)
187: (4)          array([1, 2, 3, 4, 5, 6])
188: (4)          This function will not preserve masking of MaskedArray inputs.
189: (4)          >>> a = np.ma.arange(3)
190: (4)          >>> a[1] = np.ma.masked
191: (4)          >>> b = np.arange(2, 5)
192: (4)          >>> a
193: (4)          masked_array(data=[0, --, 2],
194: (17)            mask=[False, True, False],
195: (11)            fill_value=999999)
196: (4)          >>> b
197: (4)          array([2, 3, 4])
198: (4)          >>> np.concatenate([a, b])
199: (4)          masked_array(data=[0, 1, 2, 2, 3, 4],

        return arrays
@array_function_from_c_func_and_dispatcher(_multiarray_umath.inner)
def inner(a, b):
    """
    inner(a, b, /)
    Inner product of two arrays.
    Ordinary inner product of vectors for 1-D arrays (without complex
    conjugation), in higher dimensions a sum product over the last axes.
    Parameters
    -----
    a, b : array_like
        If `a` and `b` are nonscalar, their last dimensions must match.
    Returns
    -----
    out : ndarray
        If `a` and `b` are both
        scalars or both 1-D arrays then a scalar is returned; otherwise
        an array is returned.
        ``out.shape = (*a.shape[:-1], *b.shape[:-1])``
    Raises
    -----
    ValueError
        If both `a` and `b` are nonscalar and their last dimensions have
        different sizes.
    See Also
    -----
    tensordot : Sum products over arbitrary axes.
    dot : Generalised matrix product, using second last dimension of `b` .
    einsum : Einstein summation convention.
    Notes
    -----
    For vectors (1-D arrays) it computes the ordinary inner-product::
        np.inner(a, b) = sum(a[:]*b[:])
    More generally, if ``ndim(a) = r > 0`` and ``ndim(b) = s > 0``::
        np.inner(a, b) = np.tensordot(a, b, axes=(-1,-1))
    or explicitly::
        np.inner(a, b)[i0,...,ir-2,j0,...,js-2]
        = sum(a[i0,...,ir-2,:]*b[j0,...,js-2,:])
    In addition `a` or `b` may be scalars, in which case::
        np.inner(a,b) = a*b
    Examples
    -----
    Ordinary inner product for vectors:
    >>> a = np.array([1,2,3])
    >>> b = np.array([0,1,0])
    >>> np.inner(a, b)
    2
    Some multidimensional examples:
    >>> a = np.arange(24).reshape((2,3,4))
    >>> b = np.arange(4)
    >>> c = np.inner(a, b)
    >>> c.shape
    (2, 3)
    >>> c
    array([[ 14,  38,  62],
           [ 86, 110, 134]])
    >>> a = np.arange(2).reshape((1,1,2))
    >>> b = np.arange(6).reshape((3,2))
    >>> c = np.inner(a, b)
    >>> c.shape
    (1, 1, 3)
    >>> c
    array([[[1, 3, 5]]])
    An example where `b` is a scalar:
    >>> np.inner(np.eye(2), 7)
    array([[7., 0.],
           [0., 7.]])
    """
    return (a, b)

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

279: (0) @array_function_from_c_func_and_dispatcher(_multiarray_umath.where)
280: (0) def where(condition, x=None, y=None):
281: (4)     """
282: (4)         where(condition, [x, y], /)
283: (4)         Return elements chosen from `x` or `y` depending on `condition`.
284: (4)         .. note::
285: (8)             When only `condition` is provided, this function is a shorthand for
286: (8)             ``np.asarray(condition).nonzero()``. Using `nonzero` directly should
be
287: (8)             preferred, as it behaves correctly for subclasses. The rest of this
288: (8)             documentation covers only the case where all three arguments are
289: (8)             provided.
290: (4)         Parameters
291: (4)         -----
292: (4)             condition : array_like, bool
293: (8)                 Where True, yield `x`, otherwise yield `y`.
294: (4)             x, y : array_like
295: (8)                 Values from which to choose. `x`, `y` and `condition` need to be
296: (8)                 broadcastable to some shape.
297: (4)         Returns
298: (4)         -----
299: (4)             out : ndarray
300: (8)                 An array with elements from `x` where `condition` is True, and
elements
301: (8)                 from `y` elsewhere.
302: (4)         See Also
303: (4)         -----
304: (4)             choose
305: (4)             nonzero : The function that is called when x and y are omitted
306: (4)         Notes
307: (4)         -----
308: (4)             If all the arrays are 1-D, `where` is equivalent to::
309: (8)                 [xv if c else yv
310: (9)                     for c, xv, yv in zip(condition, x, y)]
311: (4)         Examples
312: (4)         -----
313: (4)             >>> a = np.arange(10)
314: (4)             >>> a
315: (4)             array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
316: (4)             >>> np.where(a < 5, a, 10*a)
317: (4)             array([ 0,  1,  2,  3,  4, 50, 60, 70, 80, 90])
318: (4)             This can be used on multidimensional arrays too:
319: (4)             >>> np.where([[True, False], [True, True]],
320: (4)                         [[1, 2], [3, 4]],
321: (4)                         [[9, 8], [7, 6]])
322: (4)             array([[1, 8],
323: (11)                 [3, 4]])
324: (4)             The shapes of x, y, and the condition are broadcast together:
325: (4)             >>> x, y = np.ogrid[:3, :4]
326: (4)             >>> np.where(x < y, x, 10 + y) # both x and 10+y are broadcast
327: (4)             array([[10,  0,  0,  0],
328: (11)                 [10, 11,  1,  1],
329: (11)                 [10, 11, 12,  2]])
330: (4)             >>> a = np.array([[0, 1, 2],
331: (4)                         [0, 2, 4],
332: (4)                         [0, 3, 6]])
333: (4)             >>> np.where(a < 4, a, -1) # -1 is broadcast
334: (4)             array([[ 0,  1,  2],
335: (11)                 [ 0,  2, -1],
336: (11)                 [ 0,  3, -1]])
337: (4)             """
338: (4)             return (condition, x, y)
339: (0) @array_function_from_c_func_and_dispatcher(_multiarray_umath.lexsort)
340: (0) def lexsort(keys, axis=None):
341: (4)     """
342: (4)         lexsort(keys, axis=-1)
343: (4)         Perform an indirect stable sort using a sequence of keys.
344: (4)         Given multiple sorting keys, which can be interpreted as columns in a
spreadsheet, lexsort returns an array of integer indices that describes

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

346: (4)          the sort order by multiple columns. The last key in the sequence is used
347: (4)          for the primary sort order, the second-to-last key for the secondary sort
348: (4)          order, and so on. The keys argument must be a sequence of objects that
349: (4)          can be converted to arrays of the same shape. If a 2D array is provided
350: (4)          for the keys argument, its rows are interpreted as the sorting keys and
351: (4)          sorting is according to the last row, second last row etc.
352: (4)          Parameters
353: (4)
354: (4)          keys : (k, N) array or tuple containing k (N,) -shaped sequences
355: (8)          The `k` different "columns" to be sorted. The last column (or row if
356: (8)          `keys` is a 2D array) is the primary sort key.
357: (4)          axis : int, optional
358: (8)          Axis to be indirectly sorted. By default, sort over the last axis.
359: (4)          Returns
360: (4)
361: (4)          indices : (N,) ndarray of ints
362: (8)          Array of indices that sort the keys along the specified axis.
363: (4)          See Also
364: (4)
365: (4)          argsort : Indirect sort.
366: (4)          ndarray.sort : In-place sort.
367: (4)          sort : Return a sorted copy of an array.
368: (4)          Examples
369: (4)
370: (4)          Sort names: first by surname, then by name.
371: (4)          >>> surnames = ('Hertz', 'Galilei', 'Hertz')
372: (4)          >>> first_names = ('Heinrich', 'Galileo', 'Gustav')
373: (4)          >>> ind = np.lexsort((first_names, surnames))
374: (4)          >>> ind
375: (4)          array([1, 2, 0])
376: (4)          >>> [surnames[i] + ", " + first_names[i] for i in ind]
377: (4)          ['Galilei, Galileo', 'Hertz, Gustav', 'Hertz, Heinrich']
378: (4)          Sort two columns of numbers:
379: (4)          >>> a = [1, 5, 1, 4, 3, 4, 4] # First column
380: (4)          >>> b = [9, 4, 0, 4, 0, 2, 1] # Second column
381: (4)          >>> ind = np.lexsort((b, a)) # Sort by a, then by b
382: (4)          >>> ind
383: (4)          array([2, 0, 4, 6, 5, 3, 1])
384: (4)          >>> [(a[i], b[i]) for i in ind]
385: (4)          [(1, 0), (1, 9), (3, 0), (4, 1), (4, 2), (4, 4), (5, 4)]
386: (4)          Note that sorting is first according to the elements of ``a``.
387: (4)          Secondary sorting is according to the elements of ``b``.
388: (4)          A normal ``argsort`` would have yielded:
389: (4)          >>> [(a[i], b[i]) for i in np.argsort(a)]
390: (4)          [(1, 9), (1, 0), (3, 0), (4, 4), (4, 2), (4, 1), (5, 4)]
391: (4)          Structured arrays are sorted lexically by ``argsort``:
392: (4)          >>> x = np.array([(1, 9), (5, 4), (1, 0), (4, 4), (3, 0), (4, 2), (4, 1)], ...
393: (4)                      dtype=np.dtype([('x', int), ('y', int)]))
394: (4)          >>> np.argsort(x) # or np.argsort(x, order=('x', 'y'))
395: (4)          array([2, 0, 4, 6, 5, 3, 1])
396: (4)          """
397: (4)          if isinstance(keys, tuple):
398: (8)              return keys
399: (4)
400: (8)          else:
401: (0)              return (keys,)
402: (0)          @array_function_from_c_func_and_dispatcher(_multiarray_umath.can_cast)
403: (4)          def can_cast(from_, to, casting=None):
404: (4)              """
405: (4)                  can_cast(from_, to, casting='safe')
406: (4)                  Returns True if cast between data types can occur according to the
407: (4)                  casting rule. If from is a scalar or array scalar, also returns
408: (4)                  True if the scalar value can be cast without overflow or truncation
409: (4)                  to an integer.
410: (4)                  Parameters
411: (4)
412: (8)                  from_ : dtype, dtype specifier, scalar, or array
413: (4)                      Data type, scalar, or array to cast from.
414: (8)                  to : dtype or dtype specifier
415: (4)                      Data type to cast to.

```

```

415: (4)           casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
416: (8)           Controls what kind of data casting may occur.
417: (10)          * 'no' means the data types should not be cast at all.
418: (10)          * 'equiv' means only byte-order changes are allowed.
419: (10)          * 'safe' means only casts which can preserve values are allowed.
420: (10)          * 'same_kind' means only safe casts or casts within a kind,
421: (12)            like float64 to float32, are allowed.
422: (10)          * 'unsafe' means any data conversions may be done.
423: (4)           Returns
424: (4)           -----
425: (4)           out : bool
426: (8)             True if cast can occur according to the casting rule.
427: (4)           Notes
428: (4)           -----
429: (4)             .. versionchanged:: 1.17.0
430: (7)               Casting between a simple data type and a structured one is possible
only
431: (7)               for "unsafe" casting. Casting to multiple fields is allowed, but
432: (7)               casting from multiple fields is not.
433: (4)             .. versionchanged:: 1.9.0
434: (7)               Casting from numeric to string types in 'safe' casting mode requires
435: (7)               that the string dtype length is long enough to store the maximum
436: (7)               integer/float value converted.

524: (4)     dtype('float64')
525: (4)     >>> np.min_scalar_type(np.arange(4,dtype='f8'))
526: (4)     dtype('float64')
527: (4)     """
528: (4)             return (a,)
529: (0) @array_function_from_c_func_and_dispatcher(_multiarray_umath.result_type)
530: (0) def result_type(*arrays_and_dtypes):
531: (4) """
532: (4)     result_type(*arrays_and_dtypes)
533: (4)     Returns the type that results from applying the NumPy
534: (4)     type promotion rules to the arguments.
535: (4)     Type promotion in NumPy works similarly to the rules in languages
536: (4)     like C++, with some slight differences. When both scalars and
537: (4)     arrays are used, the array's type takes precedence and the actual value
538: (4)     of the scalar is taken into account.
539: (4)     For example, calculating 3*a, where a is an array of 32-bit floats,
540: (4)     intuitively should result in a 32-bit float output. If the 3 is a
541: (4)     32-bit integer, the NumPy rules indicate it can't convert losslessly
542: (4)     into a 32-bit float, so a 64-bit float should be the result type.
543: (4)     By examining the value of the constant, '3', we see that it fits in
544: (4)     an 8-bit integer, which can be cast losslessly into the 32-bit float.
545: (4)     Parameters
546: (4)     -----
547: (4)     arrays_and_dtypes : list of arrays and dtypes
548: (8)         The operands of some operation whose result type is needed.
549: (4)     Returns
549: (4)     -----
550: (4)     out : dtype
551: (4)

```

```

552: (8)           The result type.
553: (4)           See also
554: (4)
555: (4)           -----
556: (4)           dtype, promote_types, min_scalar_type, can_cast
557: (4)
558: (4)           Notes
559: (4)           -----
560: (4)           .. versionadded:: 1.6.0
561: (4)           The specific algorithm used is as follows.
562: (4)           Categories are determined by first checking which of boolean,
563: (4)           integer (int/uint), or floating point (float/complex) the maximum
564: (4)           kind of all the arrays and the scalars are.
565: (4)           If there are only scalars or the maximum category of the scalars
566: (4)           is higher than the maximum category of the arrays,
567: (4)           the data types are combined with :func:`promote_types`  

568: (4)           to produce the return value.
569: (4)           Otherwise, `min_scalar_type` is called on each scalar, and
570: (4)           the resulting data types are all combined with :func:`promote_types`  

571: (4)           to produce the return value.
572: (4)           The set of int values is not a subset of the uint values for types
573: (4)           with the same number of bits, something not reflected in
574: (4)           :func:`min_scalar_type`, but handled as a special case in `result_type`.
575: (4)           Examples
576: (4)           -----
577: (4)           >>> np.result_type(3, np.arange(7, dtype='i1'))
578: (4)           dtype('int8')
579: (4)           >>> np.result_type('i4', 'c8')
580: (4)           dtype('complex128')
581: (4)           >>> np.result_type(3.0, -2)
582: (4)           dtype('float64')
583: (0)           """
584: (0)           return arrays_and_dtypes
585: (4)           @array_function_from_c_func_and_dispatcher(_multiarray_umath.dot)
586: (4)           def dot(a, b, out=None):
587: (4)               """
588: (4)               dot(a, b, out=None)
589: (6)               Dot product of two arrays. Specifically,
590: (4)               - If both `a` and `b` are 1-D arrays, it is inner product of vectors
591: (6)                   (without complex conjugation).
592: (4)               - If both `a` and `b` are 2-D arrays, it is matrix multiplication,
593: (6)                   but using :func:`matmul` or ``a @ b`` is preferred.
594: (4)               - If either `a` or `b` is 0-D (scalar), it is equivalent to
595: (6)                   :func:`multiply` and using ``numpy.multiply(a, b)`` or ``a * b`` is
596: (6)                   preferred.
597: (4)               - If `a` is an N-D array and `b` is a 1-D array, it is a sum product over
598: (6)                   the last axis of `a` and `b`.
599: (6)               - If `a` is an N-D array and `b` is an M-D array (where ``M>=2``), it is a
600: (8)                   sum product over the last axis of `a` and the second-to-last axis of
601: (4)                   `b`::
602: (4)                   dot(a, b)[i,j,k,m] = sum(a[i,j,:] * b[k,:,:m])
603: (4)               It uses an optimized BLAS library when possible (see `numpy.linalg`).
604: (4)               Parameters
605: (8)               a : array_like
606: (4)                   First argument.
607: (8)               b : array_like
608: (4)                   Second argument.
609: (8)               out : ndarray, optional
610: (8)                   Output argument. This must have the exact kind that would be returned
611: (8)                   if it was not used. In particular, it must have the right type, must
612: (8)                   be C-contiguous, and its dtype must be the dtype that would be returned
613: (8)                   for `dot(a,b)`. This is a performance feature. Therefore, if these
614: (8)                   conditions are not met, an exception is raised, instead of attempting
615: (4)                   to be flexible.
616: (4)               Returns
617: (4)               -----
618: (8)               output : ndarray
619: (8)                   Returns the dot product of `a` and `b`. If `a` and `b` are both

```

```

620: (8)                                an array is returned.
621: (8)                                If `out` is given, then it is returned.
622: (4)                                Raises
623: (4)                                -----
624: (4)                                ValueError
625: (8)                                If the last dimension of `a` is not the same size as
626: (8)                                the second-to-last dimension of `b`.
627: (4)                                See Also
628: (4)                                -----
629: (4)                                vdot : Complex-conjugating dot product.
630: (4)                                tensordot : Sum products over arbitrary axes.
631: (4)                                einsum : Einstein summation convention.
632: (4)                                matmul : '@' operator as method with out parameter.
633: (4)                                linalg.multi_dot : Chained dot product.
634: (4)                                Examples
635: (4)                                -----
636: (4)                                >>> np.dot(3, 4)
637: (4)                                12
638: (4)                                Neither argument is complex-conjugated:
639: (4)                                >>> np.dot([2j, 3j], [2j, 3j])
640: (4)                                (-13+0j)
641: (4)                                For 2-D arrays it is the matrix product:
642: (4)                                >>> a = [[1, 0], [0, 1]]
643: (4)                                >>> b = [[4, 1], [2, 2]]
644: (4)                                >>> np.dot(a, b)
645: (4)                                array([[4, 1],
646: (11)                               [2, 2]])
647: (4)                                >>> a = np.arange(3*4*5*6).reshape((3,4,5,6))
648: (4)                                >>> b = np.arange(3*4*5*6)[::-1].reshape((5,4,6,3))
649: (4)                                >>> np.dot(a, b)[2,3,2,1,2,2]
650: (4)                                499128
651: (4)                                >>> sum(a[2,3,2,:]*b[1,2,:,:2])
652: (4)                                499128
653: (4)                                """
654: (4)                                return (a, b, out)
655: (0) @array_function_from_c_func_and_dispatcher(_multiarray_umath.vdot)
656: (0) def vdot(a, b):
657: (4)     """
658: (4)     vdot(a, b, /)
659: (4)     Return the dot product of two vectors.
660: (4)     The vdot(`a`, `b`) function handles complex numbers differently than
661: (4)     dot(`a`, `b`). If the first argument is complex the complex conjugate
662: (4)     of the first argument is used for the calculation of the dot product.
663: (4)     Note that `vdot` handles multidimensional arrays differently than `dot`:
664: (4)     it does *not* perform a matrix product, but flattens input arguments
665: (4)     to 1-D vectors first. Consequently, it should only be used for vectors.
666: (4)     Parameters
667: (4)     -----
668: (4)     a : array_like
669: (8)     If `a` is complex the complex conjugate is taken before calculation
670: (8)     of the dot product.
671: (4)     b : array_like
672: (8)     Second argument to the dot product.
673: (4)     Returns
674: (4)     -----
675: (4)     output : ndarray
676: (8)     Dot product of `a` and `b`. Can be an int, float, or
677: (8)     complex depending on the types of `a` and `b`.
678: (4)     See Also
679: (4)     -----
680: (4)     dot : Return the dot product without using the complex conjugate of the
681: (10)    first argument.
682: (4)     Examples
683: (4)     -----
684: (4)     >>> a = np.array([1+2j, 3+4j])
685: (4)     >>> b = np.array([5+6j, 7+8j])
686: (4)     >>> np.vdot(a, b)
687: (4)     (70-8j)
688: (4)     >>> np.vdot(b, a)

```

```

689: (4) (70+8j)
690: (4) Note that higher-dimensional arrays are flattened!
691: (4) >>> a = np.array([[1, 4], [5, 6]])
692: (4) >>> b = np.array([[4, 1], [2, 2]])
693: (4) >>> np.vdot(a, b)
694: (4) 30
695: (4) >>> np.vdot(b, a)
696: (4) 30
697: (4) >>> 1*4 + 4*1 + 5*2 + 6*2
698: (4) 30
699: (4) """
700: (4)     return (a, b)
701: (0) @array_function_from_c_func_and_dispatcher(_multiarray_umath.bincount)
702: (0) def bincount(x, weights=None, minlength=None):
703: (4) """
704: (4)     bincount(x, /, weights=None, minlength=0)
705: (4)     Count number of occurrences of each value in array of non-negative ints.
706: (4)     The number of bins (of size 1) is one larger than the largest value in
707: (4)     `x`. If `minlength` is specified, there will be at least this number
708: (4)     of bins in the output array (though it will be longer if necessary,
709: (4)     depending on the contents of `x`).
710: (4)     Each bin gives the number of occurrences of its index value in `x`.
711: (4)     If `weights` is specified the input array is weighted by it, i.e. if a
712: (4)     value ``n`` is found at position ``i``, ``out[n] += weight[i]`` instead
713: (4)     of ``out[n] += 1``.
714: (4)     Parameters
715: (4)     -----
716: (4)     x : array_like, 1 dimension, nonnegative ints
717: (8)         Input array.
718: (4)     weights : array_like, optional
719: (8)         Weights, array of the same shape as `x`.
720: (4)     minlength : int, optional
721: (8)         A minimum number of bins for the output array.
722: (8)         .. versionadded:: 1.6.0
723: (4)     Returns
724: (4)     -----
725: (4)     out : ndarray of ints
726: (8)         The result of binning the input array.
727: (8)         The length of `out` is equal to ``np.amax(x)+1``.
728: (4)     Raises
729: (4)     -----
730: (4)     ValueError
731: (8)         If the input is not 1-dimensional, or contains elements with negative
732: (8)         values, or if `minlength` is negative.
733: (4)     TypeError
734: (8)         If the type of the input is float or complex.
735: (4)     See Also
736: (4)     -----
737: (4)     histogram, digitize, unique
738: (4)     Examples
739: (4)     -----
740: (4)     >>> np.bincount(np.arange(5))
741: (4)     array([1, 1, 1, 1, 1])
742: (4)     >>> np.bincount(np.array([0, 1, 1, 3, 2, 1, 7]))
743: (4)     array([1, 3, 1, 1, 0, 0, 0, 1])
744: (4)     >>> x = np.array([0, 1, 1, 3, 2, 1, 7, 23])
745: (4)     >>> np.bincount(x).size == np.amax(x)+1
746: (4)     True
747: (4)     The input array needs to be of integer dtype, otherwise a
748: (4)     TypeError is raised:
749: (4)     >>> np.bincount(np.arange(5, dtype=float))
750: (4)     Traceback (most recent call last):
751: (6)     ...
752: (4)     TypeError: Cannot cast array data from dtype('float64') to dtype('int64')
753: (4)     according to the rule 'safe'
754: (4)     A possible use of ``bincount`` is to perform sums over
755: (4)     variable-size chunks of an array, using the ``weights`` keyword.
756: (4)     >>> w = np.array([0.3, 0.5, 0.2, 0.7, 1., -0.6]) # weights
757: (4)     >>> x = np.array([0, 1, 1, 2, 2, 2])

```

```

758: (4)             >>> np.bincount(x, weights=w)
759: (4)             array([ 0.3,  0.7,  1.1])
760: (4)             """
761: (4)             return (x, weights)
762: (0)

@array_function_from_c_func_and_dispatcher(_multiarray_umath.ravel_multi_index)

881: (4)          >>> A
882: (4)          array([1, 2, 3])
883: (4)          >>> A = np.array([[1, 2, 3], [4, 5, 6]])
884: (4)          >>> B = [[4, 5, 6], [7, 8, 9]]
885: (4)          >>> np.copyto(A, B)
886: (4)          >>> A
887: (4)          array([[4, 5, 6],
888: (11)            [7, 8, 9]])
889: (4)          """
890: (4)          return (dst, src, where)
891: (0)          @array_function_from_c_func_and_dispatcher(_multiarray_umath.putmask)
892: (0)          def putmask(a, /, mask, values):
893: (4)          """
894: (4)          putmask(a, mask, values)

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

895: (4)          Changes elements of an array based on conditional and input values.
896: (4)          Sets ``a.flat[n] = values[n]`` for each n where ``mask.flat[n]==True``.
897: (4)          If `values` is not the same size as `a` and `mask` then it will repeat.
898: (4)          This gives behavior different from ``a[mask] = values``.
899: (4)          Parameters
900: (4)          -----
901: (4)          a : ndarray
902: (8)          Target array.
903: (4)          mask : array_like
904: (8)          Boolean mask array. It has to be the same shape as `a`.
905: (4)          values : array_like
906: (8)          Values to put into `a` where `mask` is True. If `values` is smaller
907: (8)          than `a` it will be repeated.
908: (4)          See Also
909: (4)          -----
910: (4)          place, put, take, copyto
911: (4)          Examples
912: (4)          -----
913: (4)          >>> x = np.arange(6).reshape(2, 3)
914: (4)          >>> np.putmask(x, x>2, x**2)
915: (4)          >>> x
916: (4)          array([[ 0,  1,  2],
917: (11)             [ 9, 16, 25]])
918: (4)          If `values` is smaller than `a` it is repeated:
919: (4)          >>> x = np.arange(5)
920: (4)          >>> np.putmask(x, x>1, [-33, -44])
921: (4)          >>> x
922: (4)          array([ 0,  1, -33, -44, -33])
923: (4)          """
924: (4)          return (a, mask, values)
925: (0)          @array_function_from_c_func_and_dispatcher(_multiarray_umath.packbits)
926: (0)          def packbits(a, axis=None, bitorder='big'):
927: (4)          """
928: (4)          packbits(a, /, axis=None, bitorder='big')
929: (4)          Packs the elements of a binary-valued array into bits in a uint8 array.
930: (4)          The result is padded to full bytes by inserting zero bits at the end.
931: (4)          Parameters
932: (4)          -----
933: (4)          a : array_like
934: (8)          An array of integers or booleans whose elements should be packed to
935: (8)          bits.
936: (4)          axis : int, optional
937: (8)          The dimension over which bit-packing is done.
938: (8)          ``None`` implies packing the flattened array.
939: (4)          bitorder : {'big', 'little'}, optional
940: (8)          The order of the input bits. 'big' will mimic bin(val),
941: (8)          ``[0, 0, 0, 0, 0, 1, 1] => 3 = 0b00000011``, 'little' will
942: (8)          reverse the order so ``[1, 1, 0, 0, 0, 0, 0] => 3``.
943: (8)          Defaults to 'big'.
944: (8)          .. versionadded:: 1.17.0
945: (4)          Returns
946: (4)          -----
947: (4)          packed : ndarray
948: (8)          Array of type uint8 whose elements represent bits corresponding to the
949: (8)          logical (0 or nonzero) value of the input elements. The shape of
950: (8)          `packed` has the same number of dimensions as the input (unless `axis`
951: (8)          is None, in which case the output is 1-D).

    and 32 = 0010 0000.
    """
    return (a,)
@array_function_from_c_func_and_dispatcher(_multiarray_umath.unpackbits)
def unpackbits(a, axis=None, count=None, bitorder='big'):
    """
    unpackbits(a, /, axis=None, count=None, bitorder='big')
    Unpacks elements of a uint8 array into a binary-valued output array.
    Each element of `a` represents a bit-field that should be unpacked
    into a binary-valued output array. The shape of the output array is
    either 1-D (if `axis` is ``None``) or the same shape as the input
    array with unpacking done along the axis specified.

    Parameters
    -----
    a : ndarray, uint8 type
        Input array.
    axis : int, optional
        The dimension over which bit-unpacking is done.
        ``None`` implies unpacking the flattened array.
    count : int or None, optional
        The number of elements to unpack along `axis`, provided as a way
        of undoing the effect of packing a size that is not a multiple
        of eight. A non-negative number means to only unpack `count`
        bits. A negative number means to trim off that many bits from
        the end. ``None`` means to unpack the entire array (the
        default). Counts larger than the available number of bits will
        add zero padding to the output. Negative counts must not
        exceed the available number of bits.
        .. versionadded:: 1.17.0
    bitorder : {'big', 'little'}, optional
        The order of the returned bits. 'big' will mimic bin(val),
        ``3 = 0b00000011 => [0, 0, 0, 0, 0, 1, 1]``, 'little' will reverse
        the order to ``[1, 1, 0, 0, 0, 0, 0]``.
        Defaults to 'big'.
        .. versionadded:: 1.17.0
    Returns
    -----
    unpacked : ndarray, uint8 type
        The elements are binary-valued (0 or 1).
    See Also
    -----
    packbits : Packs the elements of a binary-valued array into bits in
               a uint8 array.
    Examples
    -----
    >>> a = np.array([[2], [7], [23]], dtype=np.uint8)
    >>> a
    array([[ 2],
           [ 7],
           [23]], dtype=uint8)
    >>> b = np.unpackbits(a, axis=1)
    >>> b
    array([[0, 0, 0, 0, 0, 0, 1, 0],
           [0, 0, 0, 0, 0, 1, 1, 1],
           [0, 0, 0, 1, 0, 1, 1, 1]], dtype=uint8)
    >>> c = np.unpackbits(a, axis=1, count=-3)
    >>> c
    array([[0, 0, 0, 0, 0],
           [0, 0, 0, 0, 0],
           [0, 0, 0, 1, 0]], dtype=uint8)
    >>> p = np.packbits(b, axis=0)
    >>> np.unpackbits(p, axis=0)
    array([[0, 0, 0, 0, 0, 0, 1, 0],
           [0, 0, 0, 0, 0, 1, 1, 1],
           [0, 0, 0, 1, 0, 1, 1, 1]], dtype=uint8)

1038: (11) [0, 0, 0, 0, 0, 0, 0, 0, 0], dtype=uint8)
1039: (4)     >>> np.array_equal(b, np.unpackbits(p, axis=0, count=b.shape[0]))
1040: (4)     True
1041: (4)     """
1042: (4)         return (a,)
1043: (0) @array_function_from_c_func_and_dispatcher(_multiarray_umath.shares_memory)
1044: (0) def shares_memory(a, b, max_work=None):
1045: (4)     """
1046: (4)         shares_memory(a, b, /, max_work=None)
1047: (4)         Determine if two arrays share memory.
1048: (4)         .. warning::
1049: (7)             This function can be exponentially slow for some inputs, unless
1050: (7)             `max_work` is set to a finite number or ``MAY_SHARE_BOUNDS``.
1051: (7)             If in doubt, use `numpy.may_share_memory` instead.
1052: (4)     Parameters
1053: (4)     -----
1054: (4)         a, b : ndarray
1055: (8)             Input arrays
1056: (4)         max_work : int, optional
1057: (8)             Effort to spend on solving the overlap problem (maximum number
1058: (8)             of candidate solutions to consider). The following special
1059: (8)             values are recognized:
1060: (8)             max_work=MAY_SHARE_EXACT (default)
1061: (12)                 The problem is solved exactly. In this case, the function returns
1062: (12)                 True only if there is an element shared between the arrays.
Finding
1063: (12)                 the exact solution may take extremely long in some cases.
1064: (8)             max_work=MAY_SHARE_BOUNDS
1065: (12)                 Only the memory bounds of a and b are checked.
1066: (4)     Raises
1067: (4)     -----
1068: (4)         numpy.exceptions.TooHardError
1069: (8)             Exceeded max_work.
1070: (4)     Returns
1071: (4)     -----
1072: (4)         out : bool
1073: (4)     See Also
1074: (4)     -----
1075: (4)         may_share_memory
1076: (4)     Examples
1077: (4)     -----
1078: (4)     >>> x = np.array([1, 2, 3, 4])
1079: (4)     >>> np.shares_memory(x, np.array([5, 6, 7]))
1080: (4)     False
1081: (4)     >>> np.shares_memory(x[:2], x)
1082: (4)     True
1083: (4)     >>> np.shares_memory(x[:2], x[1::2])
1084: (4)     False
1085: (4)     Checking whether two arrays share memory is NP-complete, and
1086: (4)     runtime may increase exponentially in the number of
1087: (4)     dimensions. Hence, `max_work` should generally be set to a finite
1088: (4)     number, as it is possible to construct examples that take
1089: (4)     extremely long to run:
1090: (4)     >>> from numpy.lib.stride_tricks import as_strided
1091: (4)     >>> x = np.zeros([192163377], dtype=np.int8)
1092: (4)     >>> x1 = as_strided(x, strides=(36674, 61119, 85569), shape=(1049, 1049,
1049))
1093: (4)     >>> x2 = as_strided(x[64023025:], strides=(12223, 12224, 1), shape=(1049,
1049, 1))
1094: (4)     >>> np.shares_memory(x1, x2, max_work=1000)
Traceback (most recent call last):
...
numpy.exceptions.TooHardError: Exceeded max_work
Running ``np.shares_memory(x1, x2)`` without `max_work` set takes

```

1140: (4)           Calculates which of the given dates are valid days, and which are not.
1141: (4)           .. versionadded:: 1.7.0
1142: (4)           Parameters
1143: (8)               -----
1144: (4)               dates : array_like of datetime64[D]
1145: (8)                   The array of dates to process.
1146: (8)               weekmask : str or array_like of bool, optional
1147: (8)                   A seven-element array indicating which of Monday through Sunday are
1148: (8)                   valid days. May be specified as a length-seven list or array, like
1149: (8)                   [1,1,1,1,1,0,0]; a length-seven string, like '1111100'; or a string
1150: (8)                   like "Mon Tue Wed Thu Fri", made up of 3-character abbreviations for
1151: (8)                   weekdays, optionally separated by white space. Valid abbreviations
1152: (8)                   are: Mon Tue Wed Thu Fri Sat Sun
1153: (8)               holidays : array_like of datetime64[D], optional
1154: (8)                   An array of dates to consider as invalid dates. They may be
1155: (8)                   specified in any order, and NaT (not-a-time) dates are ignored.
1156: (4)                   This list is saved in a normalized form that is suited for
1157: (8)                   fast calculations of valid days.
1158: (8)               busdaycal : busdaycalendar, optional
1159: (8)                   A `busdaycalendar` object which specifies the valid days. If this
1160: (8)                   parameter is provided, neither weekmask nor holidays may be
1161: (8)                   provided.
1162: (4)               out : array of bool, optional
1163: (4)                   If provided, this array is filled with the result.
1164: (4)           Returns
1165: (8)               -----
1166: (8)               out : array of bool
1167: (8)                   An array with the same shape as ``dates``, containing True for
1168: (8)                   each valid day, and False for each invalid day.

-----  

busdaycalendar : An object that specifies a custom set of valid days.  

is_busday : Returns a boolean array indicating valid days.  

busday_count : Counts how many valid days are in a half-open date range.  

Examples  

-----  

>>> # First business day in October 2011 (not accounting for holidays)  

... np.busday_offset('2011-10', 0, roll='forward')  

numpy.datetime64('2011-10-03')  

>>> # Last business day in February 2012 (not accounting for holidays)  

... np.busday_offset('2012-03', -1, roll='forward')  

numpy.datetime64('2012-02-29')  

>>> # Third Wednesday in January 2011  

... np.busday_offset('2011-01', 2, roll='forward', weekmask='Wed')  

numpy.datetime64('2011-01-19')  

>>> # 2012 Mother's Day in Canada and the U.S.  

... np.busday_offset('2012-05', 1, roll='forward', weekmask='Sun')  

numpy.datetime64('2012-05-13')  

>>> # First business day on or after a date  

... np.busday_offset('2011-03-20', 0, roll='forward')  

numpy.datetime64('2011-03-21')  

>>> np.busday_offset('2011-03-22', 0, roll='forward')  

numpy.datetime64('2011-03-22')  

>>> # First business day after a date  

... np.busday_offset('2011-03-20', 1, roll='backward')  

numpy.datetime64('2011-03-21')  

>>> np.busday_offset('2011-03-22', 1, roll='backward')  

numpy.datetime64('2011-03-23')  

"""  

    return (dates, offsets, weekmask, holidays, out)
@array_function_from_c_func_and_dispatcher(_multiarray_umath.busday_count)
def busday_count(begindates, enddates, weekmask=None, holidays=None,
                 busdaycal=None, out=None):
    """  

    busday_count(begindates, enddates, weekmask='1111100', holidays=[],  

    busdaycal=None, out=None)  

Counts the number of valid days between `begindates` and  

`enddates`, not including the day of `enddates`.  

If ``enddates`` specifies a date value that is earlier than the  

corresponding ``begindates`` date value, the count will be negative.  

.. versionadded:: 1.7.0  

Parameters  

-----  

begindates : array_like of datetime64[D]  

    The array of the first dates for counting.  

enddates : array_like of datetime64[D]  

    The array of the end dates for counting, which are excluded  

    from the count themselves.  

weekmask : str or array_like of bool, optional  

    A seven-element array indicating which of Monday through Sunday are  

    valid days. May be specified as a length-seven list or array, like  

    [1,1,1,1,1,0,0]; a length-seven string, like '1111100'; or a string  

    like "Mon Tue Wed Thu Fri", made up of 3-character abbreviations for  

    weekdays, optionally separated by white space. Valid abbreviations  

    are: Mon Tue Wed Thu Fri Sat Sun  

holidays : array_like of datetime64[D], optional  

    An array of dates to consider as invalid dates. They may be  

    specified in any order, and NaT (not-a-time) dates are ignored.  

    This list is saved in a normalized form that is suited for  

    fast calculations of valid days.  

busdaycal : busdaycalendar, optional  

    A `busdaycalendar` object which specifies the valid days. If this  

    parameter is provided, neither weekmask nor holidays may be  

    provided.  

out : array of int, optional  

    If provided, this array is filled with the result.  

Returns  

-----  

out : array of int

283: (8)              The shape and data-type of `a` define these same attributes of
284: (8)              the returned array.
285: (4)          fill_value : array_like
286: (8)              Fill value.
287: (4)          dtype : data-type, optional
288: (8)              Overrides the data type of the result.
289: (4)          order : {'C', 'F', 'A', or 'K'}, optional
290: (8)              Overrides the memory layout of the result. 'C' means C-order,
291: (8)              'F' means F-order, 'A' means 'F' if `a` is Fortran contiguous,
292: (8)              'C' otherwise. 'K' means match the layout of `a` as closely
293: (4)              as possible.
294: (8)          subok : bool, optional.
295: (8)              If True, then the newly created array will use the sub-class
296: (8)              type of `a`, otherwise it will be a base-class array. Defaults
297: (4)              to True.
298: (8)          shape : int or sequence of ints, optional.
299: (8)              Overrides the shape of the result. If order='K' and the number of
300: (8)              dimensions is unchanged, will try to keep order, otherwise,
301: (8)              order='C' is implied.
302: (4)              .. versionadded:: 1.17.0
303: (4)          Returns
304: (4)          -----
305: (4)          out : ndarray
306: (8)              Array of `fill_value` with the same shape and type as `a`.
307: (4)          See Also
308: (4)          -----
309: (4)          empty_like : Return an empty array with shape and type of input.
310: (4)          ones_like : Return an array of ones with shape and type of input.
311: (4)          zeros_like : Return an array of zeros with shape and type of input.
312: (4)          full : Return a new array of given shape filled with value.
313: (4)          Examples
314: (4)          -----
315: (4)          >>> x = np.arange(6, dtype=int)
316: (4)          >>> np.full_like(x, 1)
317: (4)          array([1, 1, 1, 1, 1, 1])
318: (4)          >>> np.full_like(x, 0.1)
319: (4)          array([0, 0, 0, 0, 0, 0])
320: (4)          >>> np.full_like(x, 0.1, dtype=np.double)
321: (4)          array([0.1, 0.1, 0.1, 0.1, 0.1, 0.1])
322: (4)          >>> np.full_like(x, np.nan, dtype=np.double)
323: (4)          array([nan, nan, nan, nan, nan, nan])
324: (4)          >>> y = np.arange(6, dtype=np.double)
325: (4)          >>> np.full_like(y, 0.1)
326: (4)          array([0.1, 0.1, 0.1, 0.1, 0.1, 0.1])

def _count_nonzero_dispatcher(a, axis=None, *, keepdims=None):
    return (a,)

@array_function_dispatch(_count_nonzero_dispatcher)
def count_nonzero(a, axis=None, *, keepdims=False):
    """
    Counts the number of non-zero values in the array ``a``.
    The word "non-zero" is in reference to the Python 2.x
    built-in method ``__nonzero__()`` (renamed ``__bool__()``)
    in Python 3.x) of Python objects that tests an object's
    "truthfulness". For example, any number is considered
    truthful if it is nonzero, whereas any string is considered
    truthful if it is not the empty string. Thus, this function
    (recursively) counts how many elements in ``a`` (and in
    sub-arrays thereof) have their ``__nonzero__()`` or ``__bool__()``
    method evaluated to ``True``.

    Parameters
    -----
    a : array_like
        The array for which to count non-zeros.
    axis : int or tuple, optional
        Axis or tuple of axes along which to count non-zeros.
        Default is None, meaning that non-zeros will be counted
        along a flattened version of ``a``.
        .. versionadded:: 1.12.0
    keepdims : bool, optional
        If this is set to True, the axes that are counted are left
        in the result as dimensions with size one. With this option,
        the result will broadcast correctly against the input array.
        .. versionadded:: 1.19.0

    Returns
    -----
    count : int or array of int
        Number of non-zero values in the array along a given axis.
        Otherwise, the total number of non-zero values in the array
        is returned.

    See Also
    -----
    nonzero : Return the coordinates of all the non-zero values.

    Examples
    -----
    >>> np.count_nonzero(np.eye(4))
    4
    >>> a = np.array([[0, 1, 7, 0],
    ...                  [3, 0, 2, 19]])
    >>> np.count_nonzero(a)
    5
    >>> np.count_nonzero(a, axis=0)
    array([1, 1, 2, 1])
    >>> np.count_nonzero(a, axis=1)
    array([2, 3])
    >>> np.count_nonzero(a, axis=1, keepdims=True)
    array([[2],
           [3]])
    """

510: (4)              ravel : Return a 1-D array containing the elements of the input array.
511: (4)              Examples
512: (4)              -----
513: (4)              >>> x = np.arange(-2, 3)
514: (4)              >>> x
515: (4)              array([-2, -1, 0, 1, 2])
516: (4)              >>> np.flatnonzero(x)
517: (4)              array([0, 1, 3, 4])
518: (4)              Use the indices of the non-zero elements as an index array to extract these elements:
519: (4)              >>> x.ravel()[np.flatnonzero(x)]
520: (4)              array([-2, -1, 1, 2])
521: (4)              """
522: (4)
523: (4)              return np.nonzero(np.ravel(a))[0]
524: (0)          def _correlate_dispatcher(a, v, mode=None):
525: (4)              return (a, v)
526: (0)          @array_function_dispatch(_correlate_dispatcher)
527: (0)          def correlate(a, v, mode='valid'):
528: (4)              """
529: (4)              Cross-correlation of two 1-dimensional sequences.
530: (4)              This function computes the correlation as generally defined in signal processing texts:
531: (4)

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

532: (4) .. math:: c_k = \sum_n a_{n+k} \cdot \overline{v}_n
533: (4) with a and v sequences being zero-padded where necessary and
534: (4) :math:`\overline{x}` denoting complex conjugation.
535: (4) Parameters
536: (4) -----
537: (4) a, v : array_like
538: (8) Input sequences.
539: (4) mode : {'valid', 'same', 'full'}, optional
540: (8) Refer to the `convolve` docstring. Note that the default
541: (8) is 'valid', unlike `convolve`, which uses 'full'.
542: (4) old_behavior : bool
543: (8) `old_behavior` was removed in NumPy 1.10. If you need the old
544: (8) behavior, use `multiarray.correlate`.
545: (4) Returns
546: (4) -----
547: (4) out : ndarray
548: (8) Discrete cross-correlation of `a` and `v`.
549: (4) See Also
550: (4) -----
551: (4) convolve : Discrete, linear convolution of two one-dimensional sequences.
552: (4) multiarray.correlate : Old, no conjugate, version of correlate.
553: (4) scipy.signal.correlate : uses FFT which has superior performance on large
arrays.
554: (4) Notes
555: (4) -----
556: (4) The definition of correlation above is not unique and sometimes
correlation
557: (4) may be defined differently. Another common definition is:
558: (4) .. math:: c'_k = \sum_n a_{\{n\}} \cdot \overline{v}_{\{n+k\}}
559: (4) which is related to :math:`c_k` by :math:`c'_k = c_{-k}`.
560: (4) `numpy.correlate` may perform slowly in large arrays (i.e. n = 1e5)
because it does
561: (4) not use the FFT to compute the convolution; in that case,
`scipy.signal.correlate` might
562: (4) be preferable.
563: (4) Examples
564: (4) -----
565: (4) >>> np.correlate([1, 2, 3], [0, 1, 0.5])
566: (4) array([3.5])
567: (4) >>> np.correlate([1, 2, 3], [0, 1, 0.5], "same")
568: (4) array([2., 3.5, 3.])
569: (4) >>> np.correlate([1, 2, 3], [0, 1, 0.5], "full")
570: (4) array([0.5, 2., 3.5, 3., 0.])
571: (4) Using complex sequences:
572: (4) >>> np.correlate([1+1j, 2, 3-1j], [0, 1, 0.5j], 'full')
573: (4) array([ 0.5-0.5j, 1.0+0.j, 1.5-1.5j, 3.0-1.j, 0.0+0.j])
574: (4) Note that you get the time reversed, complex conjugated result
575: (4) (:math:`\overline{c}_{-k}`) when the two input sequences a and v change
places:
576: (4) >>> np.correlate([0, 1, 0.5j], [1+1j, 2, 3-1j], 'full')
577: (4) array([ 0.0+0.j, 3.0+1.j, 1.5+1.5j, 1.0+0.j, 0.5+0.5j])
578: (4) """
579: (4) return multiarray.correlate2(a, v, mode)
580: (4) def _convolve_dispatcher(a, v, mode=None):
581: (0)     return (a, v)
582: (4) @array_function_dispatch(_convolve_dispatcher)
583: (0) def convolve(a, v, mode='full'):
584: (0)     """
585: (4) Returns the discrete, linear convolution of two one-dimensional sequences.
586: (4) The convolution operator is often seen in signal processing, where it
587: (4) models the effect of a linear time-invariant system on a signal [1]_. In
588: (4) probability theory, the sum of two independent random variables is
589: (4) distributed according to the convolution of their individual
590: (4) distributions.
591: (4) If `v` is longer than `a`, the arrays are swapped before computation.
592: (4) Parameters
593: (4) -----
594: (4) a : (N,) array_like
595: (4) First one-dimensional input array.
596: (8)
```

```

597: (4)           v : (M,) array_like
598: (8)             Second one-dimensional input array.
599: (4)           mode : {'full', 'valid', 'same'}, optional
600: (8)             'full':
601: (10)            By default, mode is 'full'. This returns the convolution
602: (10)            at each point of overlap, with an output shape of (N+M-1,). At
603: (10)            the end-points of the convolution, the signals do not overlap
604: (10)            completely, and boundary effects may be seen.
605: (8)           'same':
606: (10)            Mode 'same' returns output of length ``max(M, N)` `. Boundary
607: (10)            effects are still visible.
608: (8)           'valid':
609: (10)            Mode 'valid' returns output of length
610: (10)            ``max(M, N) - min(M, N) + 1`` . The convolution product is only
given
611: (10)            for points where the signals overlap completely. Values outside
612: (10)            the signal boundary have no effect.
613: (4)           Returns
614: (4)           -----
615: (4)           out : ndarray
616: (8)             Discrete, linear convolution of `a` and `v` .
617: (4)           See Also
618: (4)           -----
619: (4)           scipy.signal.fftconvolve : Convolve two arrays using the Fast Fourier
620: (31)             Transform.
621: (4)           scipy.linalg.toeplitz : Used to construct the convolution operator.
622: (4)           polymul : Polynomial multiplication. Same output as convolve, but also
623: (14)             accepts poly1d objects as input.
624: (4)           Notes
625: (4)           -----
626: (4)             The discrete convolution operation is defined as
627: (4)             .. math:: (a * v)_n = \sum_{m = -\infty}^{\infty} a_m v_{n - m}
628: (4)             It can be shown that a convolution :math:`x(t) * y(t)` in time/space
629: (4)             is equivalent to the multiplication :math:`X(f) Y(f)` in the Fourier
630: (4)             domain, after appropriate padding (padding is necessary to prevent
631: (4)             circular convolution). Since multiplication is more efficient (faster)
632: (4)             than convolution, the function `scipy.signal.fftconvolve` exploits the
633: (4)             FFT to calculate the convolution of large data-sets.
634: (4)           References
635: (4)           -----
636: (4)             .. [1] Wikipedia, "Convolution",
637: (8)               https://en.wikipedia.org/wiki/Convolution
638: (4)           Examples
639: (4)           -----
640: (4)             Note how the convolution operator flips the second array
641: (4)             before "sliding" the two across one another:
642: (4)             >>> np.convolve([1, 2, 3], [0, 1, 0.5])
643: (4)             array([0. , 1. , 2.5, 4. , 1.5])
644: (4)             Only return the middle values of the convolution.
645: (4)             Contains boundary effects, where zeros are taken
646: (4)             into account:
647: (4)             >>> np.convolve([1,2,3],[0,1,0.5], 'same')
648: (4)             array([1. , 2.5, 4. ])
649: (4)             The two arrays are of the same length, so there
650: (4)             is only one position where they completely overlap:
651: (4)             >>> np.convolve([1,2,3],[0,1,0.5], 'valid')
652: (4)             array([2.5])
653: (4)             """
654: (4)             a, v = array(a, copy=False, ndmin=1), array(v, copy=False, ndmin=1)
655: (4)             if (len(v) > len(a)):
656: (8)                 a, v = v, a
657: (4)             if len(a) == 0:
658: (8)                 raise ValueError('a cannot be empty')
659: (4)             if len(v) == 0:
660: (8)                 raise ValueError('v cannot be empty')
661: (4)             return multiarray.correlate(a, v[::-1], mode)

def outer(a, b, out=None):
    """
    Compute the outer product of two vectors.
    Given two vectors `a` and `b` of length ``M`` and ``N``, respectively,
    the outer product [1]_ is::
        [[a_0*b_0  a_0*b_1 ... a_0*b_{N-1} ]
         [a_1*b_0      .
         [ ...
         [a_{M-1}*b_0          a_{M-1}*b_{N-1} ]]
    Parameters
    -----
    a : (M,) array_like
        First input vector. Input is flattened if
        not already 1-dimensional.
    b : (N,) array_like
        Second input vector. Input is flattened if
        not already 1-dimensional.
    out : (M, N) ndarray, optional
        A location where the result is stored
        .. versionadded:: 1.9.0
    Returns
    -----
    out : (M, N) ndarray
        ``out[i, j] = a[i] * b[j]``
    See also
    -----
    inner
    einsum : ``einsum('i,j->ij', a.ravel(), b.ravel())`` is the equivalent.
    ufunc.outer : A generalization to dimensions other than 1D and other
                  operations. ``np.multiply.outer(a.ravel(), b.ravel())`` is the equivalent.
    tensordot : ``np.tensordot(a.ravel(), b.ravel(), axes=(((), ()))`` is the equivalent.

           pg. 8.
    Examples
    -----
    Make a (*very* coarse) grid for computing a Mandelbrot set:
    >>> rl = np.outer(np.ones((5,)), np.linspace(-2, 2, 5))
    >>> rl
    array([[-2., -1.,  0.,  1.,  2.],
           [-2., -1.,  0.,  1.,  2.],
           [-2., -1.,  0.,  1.,  2.],
           [-2., -1.,  0.,  1.,  2.],
           [-2., -1.,  0.,  1.,  2.]])
    >>> im = np.outer(1j*np.linspace(2, -2, 5), np.ones((5,)))
    >>> im
    array([[0.+2.j, 0.+2.j, 0.+2.j, 0.+2.j, 0.+2.j],
           [0.+1.j, 0.+1.j, 0.+1.j, 0.+1.j, 0.+1.j],
           [0.+0.j, 0.+0.j, 0.+0.j, 0.+0.j, 0.+0.j],
           [0.-1.j, 0.-1.j, 0.-1.j, 0.-1.j, 0.-1.j],
           [0.-2.j, 0.-2.j, 0.-2.j, 0.-2.j, 0.-2.j]])
    >>> grid = rl + im
    >>> grid
    array([[-2.+2.j, -1.+2.j,  0.+2.j,  1.+2.j,  2.+2.j],
           [-2.+1.j, -1.+1.j,  0.+1.j,  1.+1.j,  2.+1.j],
           [-2.+0.j, -1.+0.j,  0.+0.j,  1.+0.j,  2.+0.j],
           [-2.-1.j, -1.-1.j,  0.-1.j,  1.-1.j,  2.-1.j],
           [-2.-2.j, -1.-2.j,  0.-2.j,  1.-2.j,  2.-2.j]])
    An example using a "vector" of letters:
    >>> x = np.array(['a', 'b', 'c'], dtype=object)
    >>> np.outer(x, [1, 2, 3])
    array([['a', 'aa', 'aaa'],
           ['b', 'bb', 'bbb'],
           ['c', 'cc', 'ccc']], dtype=object)
    """

741: (4)                 """
742: (4)                 Compute tensor dot product along specified axes.
743: (4)                 Given two tensors, `a` and `b`, and an array_like object containing
744: (4)                 two array_like objects, ``(a_axes, b_axes)``, sum the products of
745: (4)                 `a`'s and `b`'s elements (components) over the axes specified by
746: (4)                 ``a_axes`` and ``b_axes``. The third argument can be a single non-negative
747: (4)                 integer_like scalar, ``N``; if it is such, then the last ``N`` dimensions
748: (4)                 of `a` and the first ``N`` dimensions of `b` are summed over.
749: (4)                 Parameters
750: (4)                 -----
751: (4)                 a, b : array_like
752: (8)                     Tensors to "dot".
753: (4)                 axes : int or (2,) array_like
754: (8)                     * integer_like
755: (10)                    If an int N, sum over the last N axes of `a` and the first N axes
756: (10)                    of `b` in order. The sizes of the corresponding axes must match.
757: (8)                     * (2,) array_like
758: (10)                    Or, a list of axes to be summed over, first sequence applying to
`a`,
759: (10)                    second to `b`. Both elements array_like must be of the same length.
760: (4)             Returns
761: (4)             -----
762: (4)             output : ndarray
763: (8)                 The tensor dot product of the input.
764: (4)             See Also
765: (4)             -----
766: (4)             dot, einsum
767: (4)             Notes
768: (4)             -----
769: (4)             Three common use cases are:
770: (8)                 * ``axes = 0`` : tensor product :math:`a \otimes b`
771: (8)                 * ``axes = 1`` : tensor dot product :math:`a \cdot b`
772: (8)                 * ``axes = 2`` : (default) tensor double contraction :math:`a:b`
773: (4)             When `axes` is integer_like, the sequence for evaluation will be: first
774: (4)             the -Nth axis in `a` and 0th axis in `b`, and the -1th axis in `a` and
775: (4)             Nth axis in `b` last.
776: (4)             When there is more than one axis to sum over - and they are not the last
777: (4)             (first) axes of `a` (`b`) - the argument `axes` should consist of
778: (4)             two sequences of the same length, with the first axis to sum over given
779: (4)             first in both sequences, the second axis second, and so forth.
780: (4)             The shape of the result consists of the non-contracted axes of the
781: (4)             first tensor, followed by the non-contracted axes of the second.
782: (4)             Examples
783: (4)             -----
784: (4)             A "traditional" example:
785: (4)             >>> a = np.arange(60.).reshape(3,4,5)
786: (4)             >>> b = np.arange(24.).reshape(4,3,2)
787: (4)             >>> c = np.tensordot(a,b, axes=[1,0],[0,1]))
788: (4)             >>> c.shape
789: (4)             (5, 2)
790: (4)             >>> c
791: (4)             array([[4400., 4730.],
792: (11)                 [4532., 4874.],
793: (11)                 [4664., 5018.],
794: (11)                 [4796., 5162.],
795: (11)                 [4928., 5306.]])
796: (4)             >>> # A slower but equivalent way of computing the same...
797: (4)             >>> d = np.zeros((5,2))
798: (4)             >>> for i in range(5):
799: (4)                 ...     for j in range(2):
800: (4)                     ...         for k in range(3):
801: (4)                         ...             for n in range(4):

```

```

802: (4)          ...
803: (4)          ...      d[i,j] += a[k,n,i] * b[n,k,j]
804: (4)          >>> c == d
805: (11)         array([[ True,  True],
806: (11)             [ True,  True],
807: (11)             [ True,  True],
808: (11)             [ True,  True]])
809: (4)          An extended example taking advantage of the overloading of + and \\*:
810: (4)          >>> a = np.array(range(1, 9))
811: (4)          >>> a.shape = (2, 2, 2)
812: (4)          >>> A = np.array(['a', 'b', 'c', 'd'), dtype=object)
813: (4)          >>> A.shape = (2, 2)
814: (4)          >>> a; A
815: (4)          array([[[1, 2],
816: (12)            [3, 4]],
817: (11)            [[5, 6],
818: (12)              [7, 8]]])
819: (4)          array([[['a', 'b'],
820: (11)            ['c', 'd']], dtype=object)
821: (4)          >>> np.tensordot(a, A) # third argument default is 2 for double-
contraction
822: (4)          array(['abbcccddd', 'aaaaabbbbbcccccddd'], dtype=object)
823: (4)          >>> np.tensordot(a, A, 1)
824: (4)          array([[[['acc', 'bdd'],
825: (12)            ['aaacccc', 'bbbdddd'],
826: (11)              ['aaaaaccccc', 'bbbbbddddd'],
827: (12)                ['aaaaaaaaaccccccc', 'bbbbbbbddd'], dtype=object)
828: (4)          >>> np.tensordot(a, A, 0) # tensor product (result too long to incl.)
829: (4)          array([[[[['a', 'b'],
830: (14)            ['c', 'd']],
831: (14)              ...
832: (4)          >>> np.tensordot(a, A, (0, 1))

    a : ndarray
        Input array.
    axis : int
        The axis to be rolled. The positions of the other axes do not
        change relative to one another.
    start : int, optional
        When ``start <= axis``, the axis is rolled back until it lies in
        this position. When ``start > axis``, the axis is rolled until it
        lies before this position. The default, 0, results in a "complete"
        roll. The following table describes how negative values of ``start``
        are interpreted:
        .. table::
            :align: left
            +-----+-----+
            | ``start`` | Normalized ``start`` |
            +=====+=====+
            | ``-(arr.ndim+1)`` | raise ``AxisError`` |
            +-----+-----+
            | ``-arr.ndim`` | 0 |
            +-----+-----+
            | |vdots| | |vdots| |
            +-----+-----+
            | ``-1`` | ``arr.ndim-1`` |
            +-----+-----+
            | ``0`` | ``0`` |
            +-----+-----+
            | |vdots| | |vdots| |
            +-----+-----+
            | ``arr.ndim`` | ``arr.ndim`` |
            +-----+-----+
            | ``arr.ndim + 1`` | raise ``AxisError`` |
            +-----+-----+
        .. |vdots| unicode:: U+22EE .. Vertical Ellipsis
    Returns
    -----
    res : ndarray
        For NumPy >= 1.10.0 a view of `a` is always returned. For earlier
        NumPy versions a view of `a` is returned only if the order of the
        axes is changed, otherwise the input array is returned.
    See Also
    -----
    moveaxis : Move array axes to new positions.
    roll : Roll the elements of an array by a number of positions along a
           given axis.
    Examples
    -----
    >>> a = np.ones((3,4,5,6))
    >>> np.rollaxis(a, 3, 1).shape
    (3, 6, 4, 5)
    >>> np.rollaxis(a, 2).shape

def normalize_axis_tuple(axis, ndim, argname=None, allow_duplicate=False):
    """
    Normalizes an axis argument into a tuple of non-negative integer axes.
    This handles shorthands such as ``1`` and converts them to ``(1,)``,
    as well as performing the handling of negative indices covered by
    `normalize_axis_index`.
    By default, this forbids axes from being specified multiple times.
    Used internally by multi-axis-checking logic.
    .. versionadded:: 1.13.0
    Parameters
    -----
    axis : int, iterable of int
        The un-normalized index or indices of the axis.
    ndim : int
        The number of dimensions of the array that `axis` should be normalized
        against.
    argname : str, optional
        A prefix to put before the error message, typically the name of the
        argument.
    allow_duplicate : bool, optional
        If False, the default, disallow an axis from being specified twice.
    Returns
    -----
    normalized_axes : tuple of int
        The normalized axis index, such that `0 <= normalized_axis < ndim`
    Raises
    -----
    AxisError
        If any axis provided is out of range
    ValueError
        If an axis is repeated
    See also
    -----
    normalize_axis_index : normalizing a single scalar axis
    """

    """
    Move axes of an array to new positions.
    Other axes remain in their original order.
    .. versionadded:: 1.11.0
    Parameters
    -----
    a : np.ndarray
        The array whose axes should be reordered.
    source : int or sequence of int
        Original positions of the axes to move. These must be unique.
    destination : int or sequence of int
        Destination positions for each of the original axes. These must also
        be
        unique.
    Returns
    -----
    result : np.ndarray
        Array with moved axes. This array is a view of the input array.

1342: (4)                     Return an array representing the indices of a grid.
1343: (4)                     Compute an array where the subarrays contain index values 0, 1, ...
1344: (4)                     varying only along the corresponding axis.
1345: (4)                     Parameters
1346: (4)                         -----
1347: (4)                         dimensions : sequence of ints
1348: (8)                             The shape of the grid.
1349: (4)                         dtype : dtype, optional
1350: (8)                             Data type of the result.

```

```

1351: (4) sparse : boolean, optional
1352: (8)     Return a sparse representation of the grid instead of a dense
1353: (8)     representation. Default is False.
1354: (8)     .. versionadded:: 1.17
1355: (4) Returns -----
1356: (4) grid : one ndarray or tuple of ndarrays
1357: (4)     If sparse is False:
1358: (8)         Returns one array of grid indices,
1359: (12)         ``grid.shape = (len(dimensions),) + tuple(dimensions)``.
1360: (12)
1361: (8)     If sparse is True:
1362: (12)         Returns a tuple of arrays, with
1363: (12)         ``grid[i].shape = (1, ..., 1, dimensions[i], 1, ..., 1)`` with
1364: (12)         dimensions[i] in the ith place
1365: (4) See Also -----
1366: (4) mgrid, ogrid, meshgrid
1368: (4) Notes -----
1369: (4) The output shape in the dense case is obtained by prepending the number
1370: (4) of dimensions in front of the tuple of dimensions, i.e. if `dimensions`
1371: (4) is a tuple ``r0, ..., rN-1`` of length ``N``, the output shape is
1372: (4) ``N, r0, ..., rN-1``.
1373: (4) The subarrays ``grid[k]`` contains the N-D array of indices along the
1374: (4) ``k-th`` axis. Explicitly::
1375: (4)     grid[k, i0, i1, ..., iN-1] = ik
1376: (8)
1377: (4) Examples -----
1378: (4)
1379: (4) >>> grid = np.indices((2, 3))
1380: (4) >>> grid.shape
1381: (4) (2, 2, 3)
1382: (4) >>> grid[0]      # row indices
1383: (4) array([[0, 0, 0],
1384: (11)           [1, 1, 1]])
1385: (4) >>> grid[1]      # column indices
1386: (4) array([[0, 1, 2],
1387: (11)           [0, 1, 2]])
1388: (4) The indices can be used as an index into an array.
1389: (4) >>> x = np.arange(20).reshape(5, 4)
1390: (4) >>> row, col = np.indices((2, 3))
1391: (4) >>> x[row, col]
1392: (4) array([[0, 1, 2],
1393: (11)           [4, 5, 6]])
1394: (4) Note that it would be more straightforward in the above example to
1395: (4) extract the required elements directly with ``x[:2, :3]``.
1396: (4) If sparse is set to true, the grid will be returned in a sparse
1397: (4) representation.
1398: (4) >>> i, j = np.indices((2, 3), sparse=True)
1399: (4) >>> i.shape
1400: (4) (2, 1)
1401: (4) >>> j.shape
1402: (4) (1, 3)
1403: (4) >>> i      # row indices
1404: (4) array([[0],
1405: (11)           [1]])
1406: (4) >>> j      # column indices
1407: (4) array([[0, 1, 2]])
1408: (4) """

@set_array_function_like_doc
@set_module('numpy')
def fromfunction(function, shape, *, dtype=float, like=None, **kwargs):
    """
    Construct an array by executing a function over each coordinate.
    The resulting array therefore has a value ``fn(x, y, z)`` at
    coordinate ``(x, y, z)``.

    Parameters
    -----
    function : callable
        The function is called with N parameters, where N is the rank of
        `shape`. Each parameter represents the coordinates of the array
        varying along a specific axis. For example, if `shape`
        were ``(2, 2)``, then the parameters would be
        ``array([[0, 0], [1, 1]])`` and ``array([[0, 1], [0, 1]])``.
    shape : (N,) tuple of ints
        Shape of the output array, which also determines the shape of
        the coordinate arrays passed to `function`.
    dtype : data-type, optional
        Data-type of the coordinate arrays passed to `function`.
        By default, `dtype` is float.
    ${ARRAY_FUNCTION_LIKE}
        .. versionadded:: 1.20.0

    Returns
    -----
    fromfunction : any
        The result of the call to `function` is passed back directly.
        Therefore the shape of `fromfunction` is completely determined by
        `function`. If `function` returns a scalar value, the shape of
        `fromfunction` would not match the `shape` parameter.

    See Also
    -----
    indices, meshgrid
    Notes
    -----
    Keywords other than `dtype` and `like` are passed to `function`.

    Examples
    -----
    >>> np.fromfunction(lambda i, j: i, (2, 2), dtype=float)
    array([[0., 0.],
           [1., 1.]])
    >>> np.fromfunction(lambda i, j: j, (2, 2), dtype=float)
    array([[0., 1.],
           [0., 1.]])
    >>> np.fromfunction(lambda i, j: i == j, (3, 3), dtype=int)
    array([[ True, False, False],
           [False,  True, False],
           [False, False,  True]])
    >>> np.fromfunction(lambda i, j: i + j, (3, 3), dtype=int)
    array([[0, 1, 2],
           [1, 2, 3],
           [2, 3, 4]])
    """
    if like is not None:
        return _fromfunction_with_like(
            like, function, shape, dtype=dtype, **kwargs)

@set_module('numpy')
def isscalar(element):
    """

```

```

1489: (4)          Returns True if the type of `element` is a scalar type.
1490: (4)          Parameters
1491: (4)          -----
1492: (4)          element : any
1493: (8)          Input argument, can be of any type and shape.
1494: (4)          Returns
1495: (4)          -----
1496: (4)          val : bool
1497: (8)          True if `element` is a scalar type, False if it is not.
1498: (4)          See Also
1499: (4)          -----
1500: (4)          ndim : Get the number of dimensions of an array
1501: (4)          Notes
1502: (4)          -----
1503: (4)          If you need a stricter way to identify a *numerical* scalar, use
1504: (4)          ```isinstance(x, numbers.Number)```, as that returns ``False`` for most
1505: (4)          non-numerical elements such as strings.
1506: (4)          In most cases ``np.ndim(x) == 0`` should be used instead of this function,
1507: (4)          as that will also return true for 0d arrays. This is how numpy overloads
1508: (4)          functions in the style of the ``dx`` arguments to `gradient` and the
1509: ``bins``
1510: (4)          argument to `histogram`. Some key differences:

1542: (4)          >>> np.isscalar('numpy')
1543: (4)          True
1544: (4)          NumPy supports PEP 3141 numbers:
1545: (4)          >>> from fractions import Fraction
1546: (4)          >>> np.isscalar(Fraction(5, 17))
1547: (4)          True
1548: (4)          >>> from numbers import Number
1549: (4)          >>> np.isscalar(Number())
1550: (4)          True
1551: (4)          """
1552: (4)          return (isinstance(element, generic)
1553: (12)          or type(element) in ScalarType
1554: (12)          or isinstance(element, numbers.Number))
1555: (0)          @set_module('numpy')
1556: (0)          def binary_repr(num, width=None):
1557: (4)          """
1558: (4)          Return the binary representation of the input number as a string.
1559: (4)          For negative numbers, if width is not given, a minus sign is added to the
1560: (4)          front. If width is given, the two's complement of the number is
1561: (4)          returned, with respect to that width.
1562: (4)          In a two's-complement system negative numbers are represented by the two's
1563: (4)          complement of the absolute value. This is the most common method of
1564: (4)          representing signed integers on computers [1]_. A N-bit two's-complement
1565: (4)          system can represent every integer in the range
1566: (4)          :math:`-2^{N-1}` to :math:`+2^{N-1}-1`.
1567: (4)          Parameters
1568: (4)          -----
1569: (4)          num : int
1570: (8)          Only an integer decimal number can be used.
1571: (4)          width : int, optional
1572: (8)          The length of the returned string if `num` is positive, or the length
1573: (8)          of the two's complement if `num` is negative, provided that `width` is
1574: (8)          at least a sufficient number of bits for `num` to be represented in
the
1575: (8)          designated form.
1576: (8)          If the `width` value is insufficient, it will be ignored, and `num`
will
1577: (8)          be returned in binary (`num` > 0) or two's complement (`num` < 0) form
1578: (8)          with its width equal to the minimum number of bits needed to represent
1579: (8)          the number in the designated form. This behavior is deprecated and
will
1580: (8)          later raise an error.
1581: (8)          .. deprecate:: 1.12.0
1582: (4)          Returns
1583: (4)          -----
1584: (4)          bin : str
1585: (8)          Binary representation of `num` or two's complement of `num`.
1586: (4)          See Also
1587: (4)          -----
1588: (4)          base_repr: Return a string representation of a number in the given base
1589: (15)          system.
1590: (4)          bin: Python's built-in binary representation generator of an integer.
1591: (4)          Notes
1592: (4)          -----
1593: (4)          `binary_repr` is equivalent to using `base_repr` with base 2, but about
25x
1594: (4)          faster.

-----  

a, b : array_like  

      Input arrays to compare.  

rtol : float  

      The relative tolerance parameter (see Notes).  

atol : float  

      The absolute tolerance parameter (see Notes).  

equal_nan : bool  

      Whether to compare NaN's as equal. If True, NaN's in `a` will be  

      considered equal to NaN's in `b` in the output array.  

>Returns  

-----  

y : array_like  

      Returns a boolean array of where `a` and `b` are equal within the  

      given tolerance. If both `a` and `b` are scalars, returns a single  

      boolean value.  

See Also  

-----  

allclose  

math.isclose  

Notes  

-----  

.. versionadded:: 1.7.0  

For finite values, isclose uses the following equation to test whether  

two floating point values are equivalent.  

$$\text{absolute}(a - b) \leq (\text{atol} + \text{rtol} * \text{absolute}(b))$$
  

Unlike the built-in `math.isclose`, the above equation is not symmetric  

in `a` and `b` -- it assumes `b` is the reference value -- so that  

`isclose(a, b)` might be different from `isclose(b, a)`. Furthermore,  

the default value of atol is not zero, and is used to determine what  

small values should be considered close to zero. The default value is  

appropriate for expected values of order unity: if the expected values  

are significantly smaller than one, it can result in false positives.  

`atol` should be carefully selected for the use case at hand. A zero value  

for `atol` will result in `False` if either `a` or `b` is zero.  

`isclose` is not defined for non-numeric data types.  

`bool` is considered a numeric data-type for this purpose.  

Examples  

-----  

>>> np.isclose([1e10,1e-7], [1.00001e10,1e-8])  

array([ True, False])  

>>> np.isclose([1e10,1e-8], [1.00001e10,1e-9])

293: (4)          -----
294: (4)          out : bool
295: (4)          See Also
296: (4)          -----
297: (4)          :ref:`arrays.scalars` : Overview of the numpy type hierarchy.
298: (4)          isssubtype, issubclass_
299: (4)          Examples
300: (4)          -----
301: (4)          `issubdtype` can be used to check the type of arrays:
302: (4)          >>> ints = np.array([1, 2, 3], dtype=np.int32)
303: (4)          >>> np.issubdtype(ints.dtype, np.integer)
304: (4)          True
305: (4)          >>> np.issubdtype(ints.dtype, np.floating)
306: (4)          False
307: (4)          >>> floats = np.array([1, 2, 3], dtype=np.float32)
308: (4)          >>> np.issubdtype(floats.dtype, np.integer)
309: (4)          False
310: (4)          >>> np.issubdtype(floats.dtype, np.floating)
311: (4)          True
312: (4)          Similar types of different sizes are not subtypes of each other:
313: (4)          >>> np.issubdtype(np.float64, np.float32)
314: (4)          False
315: (4)          >>> np.issubdtype(np.float32, np.float64)
316: (4)          False
317: (4)          but both are subtypes of `floating`:
318: (4)          >>> np.issubdtype(np.float64, np.floating)
319: (4)          True
320: (4)          >>> np.issubdtype(np.float32, np.floating)
321: (4)          True
322: (4)          For convenience, dtype-like objects are allowed too:
323: (4)          >>> np.issubdtype('S1', np.string_)
324: (4)          True
325: (4)          >>> np.issubdtype('i4', np.signedinteger)
326: (4)          True
327: (4)          """

457: (4)     Determine common type following standard coercion rules.
458: (4)     .. deprecated:: NumPy 1.25
459: (8)         This function is deprecated, use `numpy.promote_types` or
460: (8)         `numpy.result_type` instead. To achieve semantics for the
461: (8)         `scalar_types` argument, use `numpy.result_type` and pass the Python
462: (8)         values `0`, `0.0`, or `0j`.
463: (8)         This will give the same results in almost all cases.
464: (8)         More information and rare exception can be found in the
465: (8)         `NumPy 1.25 release notes <https://numpy.org/devdocs/release/1.25.0-notes.html>`_.
466: (4)     Parameters
467: (4)     -----
468: (4)     array_types : sequence
469: (8)         A list of dtypes or dtype convertible objects representing arrays.
470: (4)     scalar_types : sequence
471: (8)         A list of dtypes or dtype convertible objects representing scalars.
472: (4)     Returns
473: (4)     -----

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

474: (4)           datatype : dtype
475: (8)             The common data type, which is the maximum of `array_types` ignoring
476: (8)               `scalar_types`, unless the maximum of `scalar_types` is of a
477: (8)                 different kind (`dtype.kind`). If the kind is not understood, then
478: (8)                   None is returned.
479: (4)           See Also
480: (4)             -----
481: (4)               dtype, common_type, can_cast, mintypecode
482: (4)           Examples
483: (4)             -----
484: (4)               >>> np.find_common_type([], [np.int64, np.float32, complex])
485: (4)               dtype('complex128')
486: (4)               >>> np.find_common_type([np.int64, np.float32], [])
487: (4)               dtype('float64')
488: (4)               The standard casting rules ensure that a scalar cannot up-cast an
489: (4)                 array unless the scalar is of a fundamentally different kind of data
490: (4)                   (i.e. under a different hierarchy in the data type hierarchy) then
491: (4)                     the array:
492: (4)               >>> np.find_common_type([np.float32], [np.int64, np.float64])
493: (4)               dtype('float32')
494: (4)               Complex is of a different type, so it up-casts the float in the
495: (4)                 `array_types` argument:
496: (4)               >>> np.find_common_type([np.float32], [complex])
497: (4)               dtype('complex128')
498: (4)               Type specifier strings are convertible to dtypes and can therefore
499: (4)                 be used instead of dtypes:

85: (4)   See NEP-18 for example usage.
86: (4)   Parameters
87: (4)   -----
88: (4)   dispatcher : callable or None
89: (8)   Function that when called like ``dispatcher(*args, **kwargs)`` with
90: (8)   arguments from the NumPy function call returns an iterable of
91: (8)   array-like arguments to check for ``__array_function__``.
92: (8)   If `None`, the first argument is used as the single `like=` argument
93: (8)   and not passed on. A function implementing `like=` must call its
94: (8)   dispatcher with `like` as the first non-keyword argument.
95: (4)   module : str, optional
96: (8)   __module__ attribute to set on new function, e.g., ``module='numpy'``.
97: (8)   By default, module is copied from the decorated function.
98: (4)   verify : bool, optional
99: (8)   If True, verify the that the signature of the dispatcher and decorated
100: (8)  function signatures match exactly: all required and optional arguments
101: (8)  should appear in order with the same names, but the default values for
102: (8)  all optional arguments should be ``None``. Only disable verification
103: (8)  if the dispatcher's signature needs to deviate for some particular
104: (8)  reason, e.g., because the function has a signature like
105: (8)   ``func(*args, **kwargs)``.
106: (4)   docs_from_dispatcher : bool, optional
107: (8)   If True, copy docs from the dispatcher function onto the dispatched
108: (8)  function, rather than from the implementation. This is useful for
109: (8)  functions defined in C, which otherwise don't have docstrings.
110: (4)   Returns
111: (4)   -----

Record Arrays
=====
Record arrays expose the fields of structured arrays as properties.
Most commonly, ndarrays contain elements of a single type, e.g. floats,
integers, bools etc. However, it is possible for elements to be combinations
of these using structured types, such as::
    >>> a = np.array([(1, 2.0), (1, 2.0)], dtype=[('x', np.int64), ('y',
np.float64)])
    >>> a
    array([(1, 2.), (1, 2.)], dtype=[('x', '<i8'), ('y', '<f8')])
Here, each element consists of two fields: x (and int), and y (a float).
This is known as a structured array. The different fields are analogous
to columns in a spread-sheet. The different fields can be accessed as
one would a dictionary::
    >>> a['x']
    array([1, 1])
    >>> a['y']
    array([2., 2.])
Record arrays allow us to access fields as properties::
    >>> ar = np.rec.array(a)
    >>> ar.x
    array([1, 1])
    >>> ar.y
    array([2., 2.])
"""

```

70: (4)          dtype : dtype
71: (8)          The converted data-type.
72: (4)          Parameters
73: (4)
74: (4)          formats : str or list of str
75: (8)          The format description, either specified as a string with
76: (8)          comma-separated format descriptions in the form ``'f8, i4, a5'``, or
77: (8)          a list of format description strings in the form
78: (8)          ``['f8', 'i4', 'a5']``.
79: (4)          names : str or list/tuple of str
80: (8)          The field names, either specified as a comma-separated string in the
81: (8)          form ``'col1, col2, col3'``, or as a list or tuple of strings in the
82: (8)          form ``['col1', 'col2', 'col3']``.
83: (8)          An empty list can be used, in that case default field names
84: (8)          ('f0', 'f1', ...) are used.
85: (4)          titles : sequence
86: (8)          Sequence of title strings. An empty list can be used to leave titles
87: (8)          out.
88: (4)          aligned : bool, optional
89: (8)          If True, align the fields by padding as the C-compiler would.
90: (8)          Default is False.
91: (4)          byteorder : str, optional
92: (8)          If specified, all the fields will be changed to the
93: (8)          provided byte-order. Otherwise, the default byte-order is
94: (8)          used. For all available string specifiers, see `dtype.newbyteorder`.
95: (4)          See Also
96: (4)
97: (4)          dtype, typename, sctype2char
98: (4)          Examples
99: (4)
100: (4)          >>> np.format_parser(['<f8', '<i4', '<a5'], ['col1', 'col2', 'col3'],
101: (4)                      ...                           ['T1', 'T2', 'T3']).dtype
102: (4)          dtype([('T1', 'col1'), ('<f8'), ('T2', 'col2'), ('<i4'),
103: (4)                      ('T3', 'col3'), ('S5')])]
104: (4)          `names` and/or `titles` can be empty lists. If `titles` is an empty list,
105: (4)          titles will simply not appear. If `names` is empty, default field names
106: (4)          will be used.
107: (4)          >>> np.format_parser(['f8', 'i4', 'a5'], ['col1', 'col2', 'col3'],

232: (4)                 """Construct an ndarray that allows field access using attributes.
233: (4)                 Arrays may have a data-types containing fields, analogous
234: (4)                 to columns in a spread sheet. An example is ``[(x, int), (y, float)]``,
235: (4)                 where each entry in the array is a pair of ``(int, float)``. Normally,
236: (4)                 these attributes are accessed using dictionary lookups such as
237: (4)                 ``arr['x']``.
238: (4)             members
239: (4)             Parameters
240: (4)             -----
241: (4)             shape : tuple
242: (8)                 Shape of output array.
243: (4)             dtype : data-type, optional
244: (8)                 The desired data-type. By default, the data-type is determined
245: (8)                 from `formats`, `names`, `titles`, `aligned` and `byteorder`.
246: (4)             formats : list of data-types, optional
247: (8)                 A list containing the data-types for the different columns, e.g.
248: (8)                 ``['i4', 'f8', 'i4']``. `formats` does *not* support the new
249: (8)                 convention of using types directly, i.e. ``(int, float, int)``.
250: (8)                 Note that `formats` must be a list, not a tuple.
251: (8)                 Given that `formats` is somewhat limited, we recommend specifying
252: (8)                 `dtype` instead.
253: (4)             names : tuple of str, optional
254: (8)                 The name of each column, e.g. ``('x', 'y', 'z')``.
255: (4)             buf : buffer, optional
256: (8)                 By default, a new array is created of the given shape and data-type.
257: (8)                 If `buf` is specified and is an object exposing the buffer interface,
258: (8)                 the array will use the memory from the existing buffer. In this case,
259: (8)                 the `offset` and `strides` keywords are available.
260: (4)             Other Parameters
261: (4)             -----
262: (4)             titles : tuple of str, optional
263: (8)                 Aliases for column names. For example, if `names` were
264: (8)                 ``('x', 'y', 'z')`` and `titles` is
265: (8)                 ``('x_coordinate', 'y_coordinate', 'z_coordinate')``, then
266: (8)                 ``arr['x']`` is equivalent to both ``arr.x`` and ``arr.x_coordinate``.
267: (4)             byteorder : {'<', '>', '='}, optional
268: (8)                 Byte-order for all fields.
269: (4)             aligned : bool, optional
270: (8)                 Align the fields in memory as the C-compiler would.
271: (4)             strides : tuple of ints, optional
272: (8)                 Buffer (`buf`) is interpreted according to these strides (strides

```

```

273: (8)           define how many bytes each array element, row, column, etc.
274: (8)           occupy in memory).
275: (4)           offset : int, optional
276: (8)           Start reading buffer (`buf`) from this offset onwards.
277: (4)           order : {'C', 'F'}, optional
278: (8)           Row-major (C-style) or column-major (Fortran-style) order.
279: (4)           Returns
280: (4)           -----
281: (4)           rec : recarray
282: (8)           Empty array of the given shape and type.
283: (4)           See Also
284: (4)           -----
285: (4)           core.records.fromrecords : Construct a record array from data.
286: (4)           record : fundamental data-type for `recarray`.
287: (4)           format_parser : determine a data-type from formats, names, titles.
288: (4)           Notes
289: (4)           -----
290: (4)           This constructor can be compared to ``empty``: it creates a new record
291: (4)           array but does not fill it with data. To create a record array from data,
292: (4)           use one of the following methods:
293: (4)           1. Create a standard ndarray and convert it to a record array,
294: (7)             using ``arr.view(np.recarray)``
295: (4)           2. Use the `buf` keyword.
296: (4)           3. Use `np.rec.fromrecords`.
297: (4)           Examples
298: (4)           -----
299: (4)           Create an array with two fields, ``x`` and ``y``:
300: (4)           >>> x = np.array([(1.0, 2), (3.0, 4)], dtype=[('x', '<f8'), ('y', '<i8')])
301: (4)           >>> x
302: (4)           array([(1., 2), (3., 4)], dtype=[('x', '<f8'), ('y', '<i8')])
303: (4)           >>> x['x']
304: (4)           array([1., 3.])
305: (4)           View the array as a record array:
306: (4)           >>> x = x.view(np.recarray)
307: (4)           >>> x.x
308: (4)           array([1., 3.])
309: (4)           >>> x.y
310: (4)           array([2, 4])
311: (4)           Create a new, empty record array:
312: (4)           >>> np.recarray((2,),
313: (4)             ... dtype=[('x', int), ('y', float), ('z', int)]) #doctest: +SKIP
314: (4)           rec.array([-1073741821, 1.2249118382103472e-301, 24547520),
315: (11)             (3471280, 1.2134086255804012e-316, 0)],
316: (10)             dtype=[('x', '<i4'), ('y', '<f8'), ('z', '<i4')])
317: (4)             """

    Note that despite the name of this function it does not accept `str` instances.

    Parameters
    -----
    datastring : bytes-like
        Buffer of binary data
    dtype : data-type, optional
        Valid dtype for all arrays
    shape : int or tuple of ints, optional
        Shape of each array.
    offset : int, optional
        Position in the buffer to start reading from.
    formats, names, titles, aligned, byteorder :
        If `dtype` is ``None``, these arguments are passed to
        `numpy.format_parser` to construct a dtype. See that function for
        detailed documentation.

    Returns
    -----
    np.recarray
        Record array view into the data in datastring. This will be readonly
        if `datastring` is readonly.

    See Also
    -----
    numpy.frombuffer

    Examples

434: (4)               """Given array shapes, return the resulting shape and slices prefixes.
435: (4)               These help in nested concatenation.
436: (4)               Returns
437: (4)               -----
438: (4)               shape: tuple of int
439: (8)                 This tuple satisfies::
440: (12)                   shape, _ = _concatenate_shapes([arr.shape for shape in arrs],
axis)
441: (12)                   shape == concatenate(arrs, axis).shape

```

```

442: (4) slice_prefixes: tuple of (slice(start, end), )
443: (8)     For a list of arrays being concatenated, this returns the slice
444: (8)     in the larger array at axis that needs to be sliced into.
445: (8)     For example, the following holds::
446: (12)         ret = concatenate([a, b, c], axis)
447: (12)         _, (sl_a, sl_b, sl_c) = concatenate_slices([a, b, c], axis)
448: (12)         ret[(slice(None),) * axis + sl_a] == a
449: (12)         ret[(slice(None),) * axis + sl_b] == b
450: (12)         ret[(slice(None),) * axis + sl_c] == c
451: (8)     These are called slice prefixes since they are used in the recursive
452: (8)     blocking algorithm to compute the left-most slices during the
453: (8)     recursion. Therefore, they must be prepended to rest of the slice
454: (8)     that was computed deeper in the recursion.
455: (8)     These are returned as tuples to ensure that they can quickly be added
456: (8)     to existing slice tuple without creating a new tuple every time.
457: (4) """

    else:
        yield arrays

@array_function_dispatch(_block_dispatcher)
def block(arrays):
    """
    Assemble an nd-array from nested lists of blocks.
    Blocks in the innermost lists are concatenated (see `concatenate`) along
    the last dimension (-1), then these are concatenated along the
    second-last dimension (-2), and so on until the outermost list is reached.
    Blocks can be of any dimension, but will not be broadcasted using the
    rules. Instead, leading axes of size 1 are inserted, to make
    the same for all blocks. This is primarily useful for working with
    and means that code like ``np.block([v, 1])`` is valid, where
    ``v.ndim == 1``.
    When the nested list is two levels deep, this allows block matrices to be
    constructed from their components.
    .. versionadded:: 1.13.0
    Parameters
    -----
    arrays : nested list of array_like or scalars (but not tuples)
        If passed a single ndarray or scalar (a nested list of depth 0), this
        is returned unmodified (and not copied).
        Elements shapes must match along the appropriate axes (without
        broadcasting), but leading 1s will be prepended to the shape as
        necessary to make the dimensions match.
    Returns
    -----
    block_array : ndarray
        The array assembled from the given blocks.
        The dimensionality of the output is equal to the greatest of:
        * the dimensionality of all the inputs
        * the depth to which the input list is nested
    Raises
    -----
    ValueError
        * If list depths are mismatched - for instance, ``[[a, b], c]`` is
          illegal, and should be spelt ``[[a, b], [c]]``
        * If lists are empty - for instance, ``[[a, b], []]``
    See Also
    -----
    concatenate : Join a sequence of arrays along an existing axis.
    stack : Join a sequence of arrays along a new axis.
    vstack : Stack arrays in sequence vertically (row wise).
    hstack : Stack arrays in sequence horizontally (column wise).
    dstack : Stack arrays in sequence depth wise (along third axis).
    column_stack : Stack 1-D arrays as columns into a 2-D array.
    vsplit : Split an array into multiple sub-arrays vertically (row-wise).

```

```

576: (4)          Notes
577: (4)          -----
578: (4)          When called with only scalars, ``np.block`` is equivalent to an ndarray
579: (4)          call. So ``np.block([[1, 2], [3, 4]])`` is equivalent to
580: (4)          ``np.array([[1, 2], [3, 4]])``.
581: (4)          This function does not enforce that the blocks lie on a fixed grid.
582: (4)          ``np.block([[a, b], [c, d]])`` is not restricted to arrays of the form::
583: (8)          AAAabb
584: (8)          AAAabb
585: (8)          cccDD
586: (4)          But is also allowed to produce, for some ``a, b, c, d``:::
587: (8)          AAAabb
588: (8)          AAAabb
589: (8)          cDDDD
590: (4)          Since concatenation happens along the last axis first, `block` is _not_
591: (4)          capable of producing the following directly:::
592: (8)          AAAabb
593: (8)          cccbb
594: (8)          cccDD
595: (4)          Matlab's "square bracket stacking", ``[A, B, ...; p, q, ...]``, is
596: (4)          equivalent to ``np.block([[A, B, ...], [p, q, ...]])``.
597: (4)          Examples
598: (4)          -----
599: (4)          The most common use of this function is to build a block matrix
600: (4)          >>> A = np.eye(2) * 2
601: (4)          >>> B = np.eye(3) * 3
602: (4)          >>> np.block([
603: (4)              ...      [A,                      np.zeros((2, 3))],
604: (4)              ...      [np.ones((3, 2)), B        ],
605: (4)              ...  ])
606: (4)          array([[2., 0., 0., 0., 0.],
607: (11)             [0., 2., 0., 0., 0.],
608: (11)             [1., 1., 3., 0., 0.],
609: (11)             [1., 1., 0., 3., 0.],
610: (11)             [1., 1., 0., 0., 3.]])
611: (4)          With a list of depth 1, `block` can be used as `hstack`
612: (4)          >>> np.block([1, 2, 3])           # hstack([1, 2, 3])
613: (4)          array([1, 2, 3])
614: (4)          >>> a = np.array([1, 2, 3])
615: (4)          >>> b = np.array([4, 5, 6])
616: (4)          >>> np.block([a, b, 10])       # hstack([a, b, 10])
617: (4)          array([ 1, 2, 3, 4, 5, 6, 10])
618: (4)          >>> A = np.ones((2, 2), int)
619: (4)          >>> B = 2 * A
620: (4)          >>> np.block([A, B])           # hstack([A, B])
621: (4)          array([[1, 1, 2, 2],
622: (11)             [1, 1, 2, 2]])
623: (4)          With a list of depth 2, `block` can be used in place of `vstack`:
624: (4)          >>> a = np.array([1, 2, 3])
625: (4)          >>> b = np.array([4, 5, 6])
626: (4)          >>> np.block([[a], [b]])       # vstack([a, b])
627: (4)          array([[1, 2, 3],
628: (11)             [4, 5, 6]])
629: (4)          >>> A = np.ones((2, 2), int)
630: (4)          >>> B = 2 * A
631: (4)          >>> np.block([[A], [B]])       # vstack([A, B])
632: (4)          array([[1, 1],
633: (11)             [1, 1],
634: (11)             [2, 2],
635: (11)             [2, 2]])
636: (4)          It can also be used in places of `atleast_1d` and `atleast_2d`
637: (4)          >>> a = np.array(0)
638: (4)          >>> b = np.array([1])
639: (4)          >>> np.block([a])           # atleast_1d(a)
640: (4)          array([0])
641: (4)          >>> np.block([b])           # atleast_1d(b)
642: (4)          array([1])
643: (4)          >>> np.block([[a]])        # atleast_2d(a)
644: (4)          array([[0]])

```

```

645: (4)             >>> np.block([[b]])                      # atleast_2d(b)

## File 60 - \_add\_newdocs.py:

```

1: (0)      """
2: (0)      This is only meant to add docs to objects defined in C-extension modules.
3: (0)      The purpose is to allow easier editing of the docstrings without
4: (0)      requiring a re-compile.
5: (0)      NOTE: Many of the methods of ndarray have corresponding functions.
6: (6)          If you update these docstrings, please keep also the ones in
7: (6)          core/fromnumeric.py, core/defmatrix.py up-to-date.
8: (0)      """
9: (0)      from numpy.core.function_base import add_newdoc
10: (0)      from numpy.core.overrides import array_function_like_doc
11: (0)      add_newdoc('numpy.core', 'flatiter',
12: (4)          """
13: (4)          Flat iterator object to iterate over arrays.
14: (4)          A `flatiter` iterator is returned by ``x.flat`` for any array `x`.
15: (4)          It allows iterating over the array as if it were a 1-D array,
16: (4)          either in a for-loop or by calling its `next` method.
17: (4)          Iteration is done in row-major, C-style order (the last
18: (4)          index varying the fastest). The iterator can also be indexed using
19: (4)          basic slicing or advanced indexing.
20: (4)          See Also
21: (4)          -----
22: (4)          ndarray.flat : Return a flat iterator over an array.
23: (4)          ndarray.flatten : Returns a flattened copy of an array.
24: (4)          Notes
25: (4)          -----
26: (4)          A `flatiter` iterator can not be constructed directly from Python code
27: (4)          by calling the `flatiter` constructor.
28: (4)          Examples
29: (4)          -----
30: (4)          >>> x = np.arange(6).reshape(2, 3)
31: (4)          >>> f1 = x.flat
32: (4)          >>> type(f1)
33: (4)          <class 'numpy.flatiter'>
34: (4)          >>> for item in f1:
35: (4)              ...      print(item)
36: (4)              ...
37: (4)              0
38: (4)              1
39: (4)              2
40: (4)              3

97: (4)              [3, 4, 5]])
98: (4)          >>> f1 = x.flat
99: (4)          >>> f1.copy()
100: (4)          array([0, 1, 2, 3, 4, 5])
101: (4)          ""))
102: (0)      add_newdoc('numpy.core', 'nditer',
103: (4)          """
104: (4)          nditer(op, flags=None, op_flags=None, op_dtypes=None, order='K',
casting='safe', op_axes=None, itershape=None, buffersize=0)
105: (4)          Efficient multi-dimensional iterator object to iterate over arrays.
106: (4)          To get started using this object, see the
107: (4)          :ref:`introductory guide to array iteration <arrays.nditer>`.
108: (4)          Parameters
109: (4)          -----
110: (8)          op : ndarray or sequence of array_like
111: (4)          The array(s) to iterate over.
112: (10)         flags : sequence of str, optional
113: (4)          Flags to control the behavior of the iterator.

```

```

113: (10) * ``buffered`` enables buffering when required.
114: (10) * ``c_index`` causes a C-order index to be tracked.
115: (10) * ``f_index`` causes a Fortran-order index to be tracked.
116: (10) * ``multi_index`` causes a multi-index, or a tuple of indices
117: (12) with one per iteration dimension, to be tracked.
118: (10) * ``common_dtype`` causes all the operands to be converted to
119: (12) a common data type, with copying or buffering as necessary.
120: (10) * ``copy_if_overlap`` causes the iterator to determine if read
121: (12) operands have overlap with write operands, and make temporary
122: (12) copies as necessary to avoid overlap. False positives (needless
123: (12) copying) are possible in some cases.
124: (10) * ``delay_bufalloc`` delays allocation of the buffers until
125: (12) a reset() call is made. Allows ``allocate`` operands to
126: (12) be initialized before their values are copied into the buffers.
127: (10) * ``external_loop`` causes the ``values`` given to be
128: (12) one-dimensional arrays with multiple values instead of
129: (12) zero-dimensional arrays.
130: (10) * ``grow_inner`` allows the ``value`` array sizes to be made
131: (12) larger than the buffer size when both ``buffered`` and
132: (12) ``external_loop`` is used.
133: (10) * ``ranged`` allows the iterator to be restricted to a sub-range
134: (12) of the iterindex values.
135: (10) * ``refs_ok`` enables iteration of reference types, such as
136: (12) object arrays.
137: (10) * ``reduce_ok`` enables iteration of ``readwrite`` operands
138: (12) which are broadcasted, also known as reduction operands.
139: (10) * ``zerosize_ok`` allows `itersize` to be zero.

op_flags : list of list of str, optional
    This is a list of flags for each operand. At minimum, one of
    ``readonly``, ``readwrite``, or ``writeonly`` must be specified.
    * ``readonly`` indicates the operand will only be read from.
    * ``readwrite`` indicates the operand will be read from and written
    to.
    * ``writeonly`` indicates the operand will only be written to.
    * ``no_broadcast`` prevents the operand from being broadcasted.
    * ``contig`` forces the operand data to be contiguous.
    * ``aligned`` forces the operand data to be aligned.
    * ``nbo`` forces the operand data to be in native byte order.
    * ``copy`` allows a temporary read-only copy if required.
    * ``updateifcopy`` allows a temporary read-write copy if required.
    * ``allocate`` causes the array to be allocated if it is None
    in the ``op`` parameter.
    * ``no_subtype`` prevents an ``allocate`` operand from using a
    subtype.
    * ``arraymask`` indicates that this operand is the mask to use
    for selecting elements when writing to operands with the
    'writemasked' flag set. The iterator does not enforce this,
    but when writing from a buffer back to the array, it only
    copies those elements indicated by this mask.
    * ``writemasked`` indicates that only elements where the chosen
    ``arraymask`` operand is True will be written to.
    * ``overlap_assume_elementwise`` can be used to mark operands that
    accessed only in the iterator order, to allow less conservative
    copying when ``copy_if_overlap`` is present.

op_dtotypes : dtype or tuple of dtype(s), optional
    The required data type(s) of the operands. If copying or buffering
    is enabled, the data will be converted to/from their original types.

order : {'C', 'F', 'A', 'K'}, optional
    Controls the iteration order. 'C' means C order, 'F' means
    Fortran order, 'A' means 'F' order if all the arrays are Fortran
    contiguous, 'C' order otherwise, and 'K' means as close to the
    order the array elements appear in memory as possible. This also
    affects the element memory order of ``allocate`` operands, as they
    are allocated to be compatible with iteration order.
    Default is 'K'.

casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
    Controls what kind of data casting may occur when making a copy
    or buffering. Setting this to 'unsafe' is not recommended,

```

```

179: (8)           as it can adversely affect accumulations.
180: (8)           * 'no' means the data types should not be cast at all.
181: (8)           * 'equiv' means only byte-order changes are allowed.
182: (8)           * 'safe' means only casts which can preserve values are allowed.
183: (8)           * 'same_kind' means only safe casts or casts within a kind,
184: (10)          like float64 to float32, are allowed.
185: (8)           * 'unsafe' means any data conversions may be done.
186: (4)            op_axes : list of list of ints, optional
187: (8)              If provided, is a list of ints or None for each operands.
188: (8)              The list of axes for an operand is a mapping from the dimensions
189: (8)              of the iterator to the dimensions of the operand. A value of
190: (8)              -1 can be placed for entries, causing that dimension to be
191: (8)              treated as `newaxis`.
192: (4)            iitershape : tuple of ints, optional
193: (8)              The desired shape of the iterator. This allows ``allocate`` operands
194: (8)              with a dimension mapped by op_axes not corresponding to a dimension
195: (8)              of a different operand to get a value not equal to 1 for that
196: (8)              dimension.
197: (4)            buffersize : int, optional
198: (8)              When buffering is enabled, controls the size of the temporary
199: (8)              buffers. Set to 0 for the default value.
200: (4)            Attributes
201: (4)            -----
202: (4)            dtypes : tuple of dtype(s)
203: (8)              The data types of the values provided in `value`. This may be
204: (8)              different from the operand data types if buffering is enabled.
205: (8)              Valid only before the iterator is closed.
206: (4)            finished : bool
207: (8)              Whether the iteration over the operands is finished or not.
208: (4)            has_delayed_bufalloc : bool
209: (8)              If True, the iterator was created with the ``delay_bufalloc`` flag,
210: (8)              and no reset() function was called on it yet.
211: (4)            has_index : bool
212: (8)              If True, the iterator was created with either the ``c_index`` or
213: (8)              the ``f_index`` flag, and the property `index` can be used to
214: (8)              retrieve it.
215: (4)            has_multi_index : bool
216: (8)              If True, the iterator was created with the ``multi_index`` flag,
217: (8)              and the property `multi_index` can be used to retrieve it.
218: (4)            index
219: (8)              When the ``c_index`` or ``f_index`` flag was used, this property
220: (8)              provides access to the index. Raises a ValueError if accessed
221: (8)              and ``has_index`` is False.
222: (4)            iterationneedsapi : bool
223: (8)              Whether iteration requires access to the Python API, for example
224: (8)              if one of the operands is an object array.
225: (4)            iterindex : int
226: (8)              An index which matches the order of iteration.
227: (4)            itersize : int
228: (8)              Size of the iterator.
229: (4)            itviews
230: (8)              Structured view(s) of `operands` in memory, matching the reordered
231: (8)              and optimized iterator access pattern. Valid only before the iterator
232: (8)              is closed.
233: (4)            multi_index
234: (8)              When the ``multi_index`` flag was used, this property
235: (8)              provides access to the index. Raises a ValueError if accessed
236: (8)              accessed and ``has_multi_index`` is False.
237: (4)            ndim : int
238: (8)              The dimensions of the iterator.
239: (4)            nops : int
240: (8)              The number of iterator operands.
241: (4)            operands : tuple of operand(s)
242: (8)              The array(s) to be iterated over. Valid only before the iterator is
243: (8)              closed.
244: (4)            shape : tuple of ints
245: (8)              Shape tuple, the shape of the iterator.
246: (4)            value
247: (8)              Value of ``operands`` at current iteration. Normally, this is a

```

```

248: (8)          tuple of array scalars, but if the flag ``external_loop`` is used,
249: (8)          it is a tuple of one dimensional arrays.
250: (4)          Notes
251: (4)          -----
252: (4)          `nditer` supersedes `flatiter`. The iterator implementation behind
253: (4)          `nditer` is also exposed by the NumPy C API.
254: (4)          The Python exposure supplies two iteration interfaces, one which follows
255: (4)          the Python iterator protocol, and another which mirrors the C-style
256: (4)          do-while pattern. The native Python approach is better in most cases, but
257: (4)          if you need the coordinates or index of an iterator, use the C-style
pattern.
258: (4)          Examples
259: (4)          -----
260: (4)          Here is how we might write an ``iter_add`` function, using the
261: (4)          Python iterator protocol:
262: (4)          >>> def iter_add_py(x, y, out=None):
263: (4)              ...      addop = np.add
264: (4)              ...      it = np.nditer([x, y, out], [],
265: (4)                          ...                  [['readonly']], ['readonly'],
['writeonly','allocate']])
266: (4)              ...      with it:
267: (4)                  ...          for (a, b, c) in it:
268: (4)                      ...              addop(a, b, out=c)
269: (4)                      ...          return it.operands[2]
270: (4)          Here is the same function, but following the C-style pattern:
271: (4)          >>> def iter_add(x, y, out=None):
272: (4)              ...      addop = np.add
273: (4)              ...      it = np.nditer([x, y, out], [],
274: (4)                          ...                  [['readonly']], ['readonly'],
['writeonly','allocate']))
275: (4)              ...      with it:
276: (4)                  ...          while not it.finished:
277: (4)                      ...              addop(it[0], it[1], out=it[2])
278: (4)                      ...              it.iternext()
279: (4)                  ...          return it.operands[2]
280: (4)          Here is an example outer product function:
281: (4)          >>> def outer_it(x, y, out=None):
282: (4)              ...      mulop = np.multiply
283: (4)              ...      it = np.nditer([x, y, out], ['external_loop'],
284: (4)                          ...                  [['readonly']], ['readonly'],
['writeonly', 'allocate']],
285: (4)                          ...                  op_axes=[list(range(x.ndim)) + [-1] * y.ndim,
286: (4)  ...                               [-1] * x.ndim + list(range(y.ndim)),
287: (4)  ...                               None])
288: (4)              ...      with it:
289: (4)                  ...          for (a, b, c) in it:
290: (4)                      ...              mulop(a, b, out=c)
291: (4)                      ...          return it.operands[2]
292: (4)          >>> a = np.arange(2)+1
293: (4)          >>> b = np.arange(3)+1
294: (4)          >>> outer_it(a,b)
295: (4)          array([[1, 2, 3],
296: (11)             [2, 4, 6]])
297: (4)          Here is an example function which operates like a "lambda" ufunc:
298: (4)          >>> def luf(lamdaexpr, *args, **kwargs):
299: (4)              ...      '''luf(lambdaexpr, op1, ..., opn, out=None, order='K',
casting='safe', buffersize=0)'''
300: (4)                  ...      nargs = len(args)
301: (4)                  ...      op = (kwargs.get('out',None),) + args
302: (4)                  ...      it = np.nditer(op, ['buffered','external_loop'],
303: (4)                          ...                  [['writeonly','allocate','no_broadcast']] +
304: (4)   ...                  [['readonly','nbo','aligned']]*nargs,
305: (4)   ...                  order=kwargs.get('order','K'),
306: (4)   ...                  casting=kwargs.get('casting','safe'),
307: (4)   ...                  buffersize=kwargs.get('buffersize',0))
308: (4)                  ...      while not it.finished:
309: (4)                      ...          it[0] = lamdaexpr(*it[1:])
310: (4)                      ...          it.iternext()
311: (4)                  ...          return it.operands[0]
312: (4)          >>> a = np.arange(5)
313: (4)          >>> b = np.ones(5)

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

314: (4)          >>> luf(lambda i,j:i*i + j/2, a, b)
315: (4)          array([ 0.5,  1.5,  4.5,  9.5, 16.5])
316: (4)          If operand flags ``"writeonly"`` or ``"readwrite"`` are used the
317: (4)          operands may be views into the original data with the
318: (4)          ``WRITEREADBACKIFCOPY`` flag. In this case `nditer` must be used as a
319: (4)          context manager or the `nditer.close` method must be called before
320: (4)          using the result. The temporary data will be written back to the
321: (4)          original data when the `__exit__` function is called but not before:
322: (4)          >>> a = np.arange(6, dtype='i4')[::-2]
323: (4)          >>> with np.nditer(a, []),
324: (4)              ...      [['writeonly', 'updateifcopy']],
325: (4)              ...      casting='unsafe',
326: (4)              ...      op_dtypes=[np.dtype('f4')]) as i:
327: (4)              ...      x = i.operands[0]
328: (4)              ...      x[:] = [-1, -2, -3]
329: (4)              ...      # a still unchanged here
330: (4)          >>> a, x
331: (4)          (array([-1, -2, -3], dtype=int32), array([-1., -2., -3.], dtype=float32))
332: (4)          It is important to note that once the iterator is exited, dangling
333: (4)          references (like `x` in the example) may or may not share data with
334: (4)          the original data `a`. If writeback semantics were active, i.e. if
335: (4)          `x.base.flags.writebackifcopy` is `True`, then exiting the iterator
336: (4)          will sever the connection between `x` and `a`, writing to `x` will
337: (4)          no longer write to `a`. If writeback semantics are not active, then
338: (4)          `x.data` will still point at some part of `a.data`, and writing to
339: (4)          one will affect the other.
340: (4)          Context management and the `close` method appeared in version 1.15.0.
341: (4)          """
342: (0)          add_newdoc('numpy.core', 'nditer', ('copy',
343: (4)              """
344: (4)              copy()
345: (4)              Get a copy of the iterator in its current state.
346: (4)              Examples
347: (4)              -----
348: (4)              >>> x = np.arange(10)
349: (4)              >>> y = x + 1
350: (4)              >>> it = np.nditer([x, y])
351: (4)              >>> next(it)
352: (4)              (array(0), array(1))
353: (4)              >>> it2 = it.copy()
354: (4)              >>> next(it2)
355: (4)              (array(1), array(2))
356: (4)              """
357: (0)          add_newdoc('numpy.core', 'nditer', ('operands',
358: (4)              """
359: (4)              operands['Slice']
360: (4)              The array(s) to be iterated over. Valid only before the iterator is
closed.
361: (4)              """
362: (0)          add_newdoc('numpy.core', 'nditer', ('debug_print',
363: (4)              """
364: (4)              debug_print()
365: (4)              Print the current state of the `nditer` instance and debug info to stdout.
366: (4)              """
367: (0)          add_newdoc('numpy.core', 'nditer', ('enable_external_loop',
368: (4)              """
369: (4)              enable_external_loop()
370: (4)              When the "external_loop" was not used during construction, but
371: (4)              is desired, this modifies the iterator to behave as if the flag
372: (4)              was specified.
373: (4)              """
374: (0)          add_newdoc('numpy.core', 'nditer', ('iternext',
375: (4)              """
376: (4)              iternext()
377: (4)              Check whether iterations are left, and perform a single internal iteration
378: (4)              without returning the result. Used in the C-style pattern do-while
379: (4)              pattern. For an example, see `nditer`.
380: (4)              Returns
381: (4)              -----

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

382: (4)         iternext : bool
383: (8)           Whether or not there are iterations left.
384: (4)
385: (0)         add_newdoc('numpy.core', 'nditer', ('remove_axis',
386: (4)           """
387: (4)             remove_axis(i, /)
388: (4)             Removes axis `i` from the iterator. Requires that the flag "multi_index"
389: (4)             be enabled.
390: (4)             """
391: (0)         add_newdoc('numpy.core', 'nditer', ('remove_multi_index',

393: (4)             remove_multi_index()
394: (4)             When the "multi_index" flag was specified, this removes it, allowing
395: (4)             the internal iteration structure to be optimized further.
396: (4)             """
397: (0)         add_newdoc('numpy.core', 'nditer', ('reset',
398: (4)           """
399: (4)             reset()
400: (4)             Reset the iterator to its initial state.
401: (4)             """
402: (0)         add_newdoc('numpy.core', 'nested_iters',
403: (4)           """
404: (4)             nested_iters(op, axes, flags=None, op_flags=None, op_dtypes=None, \
405: (4)               order="K", casting="safe", buffersize=0)
406: (4)             Create nditers for use in nested loops
407: (4)             Create a tuple of `nditer` objects which iterate in nested loops over
408: (4)             different axes of the op argument. The first iterator is used in the
409: (4)             outermost loop, the last in the innermost loop. Advancing one will change
410: (4)             the subsequent iterators to point at its new element.
411: (4)             Parameters
412: (4)             -----
413: (4)             op : ndarray or sequence of array_like
414: (8)               The array(s) to iterate over.
415: (4)             axes : list of list of int
416: (8)               Each item is used as an "op_axes" argument to an nditer
417: (4)               flags, op_flags, op_dtypes, order, casting, buffersize (optional)
418: (8)                 See `nditer` parameters of the same name
419: (4)             Returns
420: (4)             -----
421: (4)             iter : tuple of nditer
422: (8)               An nditer for each item in `axes`, outermost first
423: (4)             See Also
424: (4)             -----
425: (4)             nditer
426: (4)             Examples
427: (4)             -----
428: (4)             Basic usage. Note how y is the "flattened" version of
429: (4)             [a[:, 0, :], a[:, 1, 0], a[:, 2, :]] since we specified
430: (4)             the first iter's axes as [1]
431: (4)             >>> a = np.arange(12).reshape(2, 3, 2)
432: (4)             >>> i, j = np.nested_iters(a, [[1], [0, 2]], flags=["multi_index"])
433: (4)             >>> for x in i:
434: (4)               ...     print(i.multi_index)
435: (4)               ...     for y in j:
436: (4)                 ...         print('', j.multi_index, y)
437: (4)             (0,)
438: (5)               (0, 0) 0
439: (5)               (0, 1) 1
440: (5)               (1, 0) 6
441: (5)               (1, 1) 7

445: (5)               (1, 0) 8
446: (5)               (1, 1) 9
447: (4)               (2,)
448: (5)               (0, 0) 4
449: (5)               (0, 1) 5
450: (5)               (1, 0) 10

```

```

451: (5)          (1, 1) 11
452: (4)          """
453: (0)          add_newdoc('numpy.core', 'nditer', ('close',
454: (4)          """"
455: (4)          close()
456: (4)          Resolve all writeback semantics in writeable operands.
457: (4)          .. versionadded:: 1.15.0
458: (4)          See Also
459: (4)          -----
460: (4)          :ref:`nditer-context-manager`"
461: (4)          """")
462: (0)          add_newdoc('numpy.core', 'broadcast',
463: (4)          """
464: (4)          Produce an object that mimics broadcasting.
465: (4)          Parameters
466: (4)          -----
467: (4)          in1, in2, ... : array_like
468: (8)          Input parameters.
469: (4)          Returns
470: (4)          -----
471: (4)          b : broadcast object
472: (8)          Broadcast the input parameters against one another, and
473: (8)          return an object that encapsulates the result.
474: (8)          Amongst others, it has ``shape`` and ``nd`` properties, and
475: (8)          may be used as an iterator.
476: (4)          See Also
477: (4)          -----
478: (4)          broadcast_arrays
479: (4)          broadcast_to
480: (4)          broadcast_shapes
481: (4)          Examples
482: (4)          -----
483: (4)          Manually adding two vectors, using broadcasting:
484: (4)          >>> x = np.array([[1], [2], [3]])
485: (4)          >>> y = np.array([4, 5, 6])
486: (4)          >>> b = np.broadcast(x, y)
487: (4)          >>> out = np.empty(b.shape)
488: (4)          >>> out.flat = [u+v for (u,v) in b]
489: (4)          >>> out
490: (4)          array([[5.,  6.,  7.],
491: (11)           [6.,  7.,  8.],
492: (11)           [7.,  8.,  9.]])
493: (4)          Compare against built-in broadcasting:
494: (4)          >>> x + y
495: (4)          array([[5, 6, 7],
496: (11)           [6, 7, 8],
497: (11)           [7, 8, 9]])
498: (4)          """
499: (0)          add_newdoc('numpy.core', 'broadcast', ('index',
500: (4)          """
501: (4)          current index in broadcasted result
502: (4)          Examples
503: (4)          -----
504: (4)          >>> x = np.array([[1], [2], [3]])

add_newdoc('numpy.core.multiarray', 'array',
"""
array(object, dtype=None, *, copy=True, order='K', subok=False, ndmin=0,
      like=None)
Create an array.
Parameters
-----
object : array_like
    An array, any object exposing the array interface, an object whose
    ``__array__`` method returns an array, or any (nested) sequence.
    If object is a scalar, a 0-dimensional array containing object is
    returned.
dtype : data-type, optional
    The desired data-type for the array. If not given, NumPy will try to
    a default ``dtype`` that can represent the values (by applying
    rules when necessary.)
copy : bool, optional
    If true (default), then the object is copied. Otherwise, a copy will
    only be made if ``__array__`` returns a copy, if obj is a nested
    sequence, or if a copy is needed to satisfy any of the other
    requirements (``dtype``, ``order``, etc.).
order : {'K', 'A', 'C', 'F'}, optional
    Specify the memory layout of the array. If object is not an array, the
    newly created array will be in C order (row major) unless 'F' is
    specified, in which case it will be in Fortran order (column major).
    If object is an array the following holds.
=====
order no copy                  copy=True
=====
'K'   unchanged F & C order preserved, otherwise most similar order
'A'   unchanged F order if input is F and not C, otherwise C order
'C'   C order   C order
'F'   F order   F order
=====
When ``copy=False`` and a copy is made for other reasons, the result
is
    the same as if ``copy=True``, with some exceptions for 'A', see the
    Notes section. The default order is 'K'.
subok : bool, optional
    If True, then sub-classes will be passed-through, otherwise
    the returned array will be forced to be a base-class array (default).
ndmin : int, optional
    Specifies the minimum number of dimensions that the resulting

```

```

655: (8)                                array should have. Ones will be prepended to the shape as
656: (8)                                needed to meet this requirement.
657: (4)                                ${ARRAY_FUNCTION_LIKE}
658: (8)                                .. versionadded:: 1.20.0
659: (4)                                Returns
660: (4)                                -----
661: (4)                                out : ndarray
662: (8)                                An array object satisfying the specified requirements.
663: (4)                                See Also
664: (4)                                -----
665: (4)                                empty_like : Return an empty array with shape and type of input.
666: (4)                                ones_like : Return an array of ones with shape and type of input.
667: (4)                                zeros_like : Return an array of zeros with shape and type of input.
668: (4)                                full_like : Return a new array with shape of input filled with value.
669: (4)                                empty : Return a new uninitialized array.
670: (4)                                ones : Return a new array setting values to one.
671: (4)                                zeros : Return a new array setting values to zero.
672: (4)                                full : Return a new array of given shape filled with value.
673: (4)                                Notes
674: (4)                                -----
675: (4)                                When order is 'A' and ``object`` is an array in neither 'C' nor 'F' order,
676: (4)                                and a copy is forced by a change in dtype, then the order of the result is
677: (4)                                not necessarily 'C' as expected. This is likely a bug.
678: (4)                                Examples
679: (4)                                -----
680: (4)                                >>> np.array([1, 2, 3])
681: (4)                                array([1, 2, 3])
682: (4)                                Upcasting:
683: (4)                                >>> np.array([1, 2, 3.0])
684: (4)                                array([ 1.,  2.,  3.])
685: (4)                                More than one dimension:

713: (4)                                Convert the input to an array.
714: (4)                                Parameters
715: (4)                                -----
716: (4)                                a : array_like
717: (8)                                Input data, in any form that can be converted to an array. This
718: (8)                                includes lists, lists of tuples, tuples, tuples of tuples, tuples
719: (8)                                of lists and ndarrays.
720: (4)                                dtype : data-type, optional
721: (8)                                By default, the data-type is inferred from the input data.
722: (4)                                order : {'C', 'F', 'A', 'K'}, optional
723: (8)                                Memory layout. 'A' and 'K' depend on the order of input array a.

```

```

724: (8)           'C' row-major (C-style),
725: (8)           'F' column-major (Fortran-style) memory representation.
726: (8)           'A' (any) means 'F' if `a` is Fortran contiguous, 'C' otherwise
727: (8)           'K' (keep) preserve input order
728: (8)           Defaults to 'K'.
729: (4)           ${ARRAY_FUNCTION_LIKE}
730: (8)           .. versionadded:: 1.20.0
731: (4)           Returns
732: (4)
733: (4)           out : ndarray
734: (8)           Array interpretation of `a`. No copy is performed if the input
735: (8)           is already an ndarray with matching dtype and order. If `a` is a
736: (8)           subclass of ndarray, a base class ndarray is returned.
737: (4)           See Also
738: (4)
739: (4)           asanyarray : Similar function which passes through subclasses.
740: (4)           ascontiguousarray : Convert input to a contiguous array.
741: (4)           asfarray : Convert input to a floating point ndarray.
742: (4)           asfortranarray : Convert input to an ndarray with column-major
743: (21)             memory order.
744: (4)           asarray_chkfinite : Similar function which checks input for NaNs and Infs.
745: (4)           fromiter : Create an array from an iterator.
746: (4)           fromfunction : Construct an array by executing a function on grid
747: (19)             positions.
748: (4)           Examples
749: (4)
750: (4)           Convert a list into an array:
751: (4)           >>> a = [1, 2]
752: (4)           >>> np.asarray(a)
753: (4)           array([1, 2])
754: (4)           Existing arrays are not copied:
755: (4)           >>> a = np.array([1, 2])
756: (4)           >>> np.asarray(a) is a
757: (4)           True
758: (4)           If `dtype` is set, array is copied only if dtype does not match:
759: (4)           >>> a = np.array([1, 2], dtype=np.float32)
760: (4)           >>> np.asarray(a, dtype=np.float32) is a
761: (4)           True
762: (4)           >>> np.asarray(a, dtype=np.float64) is a
763: (4)           False
764: (4)           Contrary to `asanyarray`, ndarray subclasses are not passed through:
765: (4)           >>> issubclass(np.recarray, np.ndarray)
766: (4)           True
767: (4)           >>> a = np.array([(1.0, 2), (3.0, 4)], dtype='f4,i4').view(np.recarray)
768: (4)           >>> np.asarray(a) is a
769: (4)           False
770: (4)           >>> np.asanyarray(a) is a
771: (4)           True
772: (4)           """".replace(
773: (8)             "${ARRAY_FUNCTION_LIKE}",
774: (8)             array_function_like_doc,
775: ())
776: (0)           add_newdoc('numpy.core.multiarray', 'asanyarray',
777: (4)             """
778: (4)               asanyarray(a, dtype=None, order=None, *, like=None)
779: (4)               Convert the input to an ndarray, but pass ndarray subclasses through.
780: (4)               Parameters
781: (4)
782: (4)               a : array_like
783: (8)                 Input data, in any form that can be converted to an array. This
784: (8)                 includes scalars, lists, lists of tuples, tuples, tuples of tuples,
785: (8)                 tuples of lists, and ndarrays.
786: (4)               dtype : data-type, optional
787: (8)                 By default, the data-type is inferred from the input data.
788: (4)               order : {'C', 'F', 'A', 'K'}, optional
789: (8)                 Memory layout. 'A' and 'K' depend on the order of input array a.
790: (8)                 'C' row-major (C-style),
791: (8)                 'F' column-major (Fortran-style) memory representation.
792: (8)                 'A' (any) means 'F' if `a` is Fortran contiguous, 'C' otherwise

```

```

793: (8)          'K' (keep) preserve input order
794: (8)          Defaults to 'C'.
795: (4)          ${ARRAY_FUNCTION_LIKE}
796: (8)          .. versionadded:: 1.20.0
797: (4)          Returns
798: (4)          -----
799: (4)          out : ndarray or an ndarray subclass
800: (8)          Array interpretation of `a`. If `a` is an ndarray or a subclass
801: (8)          of ndarray, it is returned as-is and no copy is performed.
802: (4)          See Also
803: (4)          -----
804: (4)          asarray : Similar function which always returns ndarrays.
805: (4)          ascontiguousarray : Convert input to a contiguous array.
806: (4)          asfarray : Convert input to a floating point ndarray.
807: (4)          asfortranarray : Convert input to an ndarray with column-major
808: (21)         memory order.
809: (4)          asarray_chkfinite : Similar function which checks input for NaNs and
810: (24)         Infs.
811: (4)          fromiter : Create an array from an iterator.
812: (4)          fromfunction : Construct an array by executing a function on grid
813: (19)         positions.

814: (4)          Examples
815: (4)          -----
816: (4)          Convert a list into an array:
817: (4)          >>> a = [1, 2]
818: (4)          >>> np.asanyarray(a)
819: (4)          array([1, 2])
820: (4)          Instances of `ndarray` subclasses are passed through as-is:
821: (4)          >>> a = np.array([(1.0, 2), (3.0, 4)], dtype='f4,i4').view(np.recarray)
822: (4)          >>> np.asanyarray(a) is a
823: (4)          True
824: (4)          """".replace(

999: (4)

-----  

shape : int or tuple of int  

    Shape of the empty array, e.g., ``(2, 3)`` or ``2``.  

dtype : data-type, optional  

    Desired output data-type for the array, e.g., `numpy.int8`. Default is  

`numpy.float64`.  

order : {'C', 'F'}, optional, default: 'C'  

    Whether to store multi-dimensional data in row-major  

(C-style) or column-major (Fortran-style) order in  

memory.  

${ARRAY_FUNCTION_LIKE}  

.. versionadded:: 1.20.0  

>Returns  

-----  

out : ndarray  

    Array of uninitialized (arbitrary) data of the given shape, dtype, and  

order. Object arrays will be initialized to None.  

See Also  

-----  

empty_like : Return an empty array with shape and type of input.  

ones : Return a new array setting values to one.  

zeros : Return a new array setting values to zero.  

full : Return a new array of given shape filled with value.  

Notes  

-----  

`empty`, unlike `zeros`, does not set the array values to zero,  

and may therefore be marginally faster. On the other hand, it requires  

the user to manually set all the values in the array, and should be  

used with caution.  

Examples  

-----  

>>> np.empty([2, 2])  

array([[ -9.74499359e+001,   6.69583040e-309],  

       [  2.13182611e-314,   3.06959433e-309]]) #uninitialized  

>>> np.empty([2, 2], dtype=int)  

array([[ -1073741821, -1067949133],  

       [  496041986,   19249760]]) #uninitialized  

""".replace(  

    "${ARRAY_FUNCTION_LIKE}",  

    array_function_like_doc,  

))  

add_newdoc('numpy.core.multiarray', 'scalar',  

"""  

scalar(dtype, obj)  

Return a new scalar array of the given type initialized with obj.  

This function is meant mainly for pickle support. `dtype` must be a  

valid data-type descriptor. If `dtype` corresponds to an object  

descriptor, then `obj` can be any object, otherwise `obj` must be a  

string. If `obj` is not given, it will be interpreted as None for object  

type and as zeros for all other types.  

""")  

add_newdoc('numpy.core.multiarray', 'zeros',  

"""  

zeros(shape, dtype=float, order='C', *, like=None)  

Return a new array of given shape and type, filled with zeros.  

Parameters  

-----  

shape : int or tuple of ints  

    Shape of the new array, e.g., ``(2, 3)`` or ``2``.  

dtype : data-type, optional  

    The desired data-type for the array, e.g., `numpy.int8`. Default is  

`numpy.float64`.  

order : {'C', 'F'}, optional, default: 'C'  

    Whether to store multi-dimensional data in row-major  

(C-style) or column-major (Fortran-style) order in  

memory.

      set_typeDict(dict)
      Set the internal dictionary that can look up an array type using a
      registered code.
      """")
      add_newdoc('numpy.core.multiarray', 'fromstring',
      """
      fromstring(string, dtype=float, count=-1, *, sep, like=None)
      A new 1-D array initialized from text data in a string.
      Parameters
      -----
      string : str
          A string containing the data.
      dtype : data-type, optional
          The data type of the array; default: float. For binary input data,
          the data must be in exactly this format. Most builtin numeric types
          supported and extension types may be supported.
      .. versionadded:: 1.18.0
          Complex dtypes.
      count : int, optional
          Read this number of `dtype` elements from the data. If this is
          negative (the default), the count will be determined from the
          length of the data.
      sep : str, optional
          The string separating numbers in the data; extra whitespace between
          elements is also ignored.
      .. deprecated:: 1.14
          Passing ``sep='''', the default, is deprecated since it will
          trigger the deprecated binary mode of this function. This mode
          interprets `string` as binary bytes, rather than ASCII text with
          decimal numbers, an operation which is better spelt
          ``frombuffer(string, dtype, count)``. If `string` contains unicode
          text, the binary mode of `fromstring` will first encode it into
          bytes using utf-8, which will not produce sane results.
      ${ARRAY_FUNCTION_LIKE}
      .. versionadded:: 1.20.0
      Returns
      -----
      arr : ndarray

1202: (4)

        -----
        out : ndarray
              The output array.
        Notes
        -----
Specify `count` to improve performance. It allows ``fromiter`` to
pre-allocate the output array, instead of resizing it on demand.
        Examples
        -----
        >>> iterable = (x*x for x in range(5))
        >>> np.fromiter(iterable, float)
        array([ 0.,  1.,  4.,  9., 16.])
A carefully constructed subarray dtype will lead to higher dimensional
results:
        >>> iterable = ((x+1, x+2) for x in range(5))
        >>> np.fromiter(iterable, dtype=np.dtype((int, 2)))
        array([[1, 2],
               [2, 3],
               [3, 4],
               [4, 5],
               [5, 6]])
        """.
replace(
        "${ARRAY_FUNCTION_LIKE}",
        array_function_like_doc,
    ))
add_newdoc('numpy.core.multiarray', 'fromfile',
"""
        fromfile(file, dtype=float, count=-1, sep='', offset=0, *, like=None)
Construct an array from data in a text or binary file.
A highly efficient way of reading binary data with a known data-type,
as well as parsing simply formatted text files. Data written using the
`tofile` method can be read using this function.
        Parameters
        -----
        file : file or str or Path
            Open file object or filename.
            .. versionchanged:: 1.17.0
                `pathlib.Path` objects are now accepted.
        dtype : data-type
            Data type of the returned array.
            For binary files, it is used to determine the size and byte-order
            of the items in the file.
            Most builtin numeric types are supported and extension types may be
            ..
            .. versionadded:: 1.18.0
                Complex dtypes.
        count : int
            Number of items to read. ``-1`` means all items (i.e., the complete
            file).
        sep : str
            Separator between items if file is a text file.
            Empty ("") separator means the file should be treated as binary.
            Spaces (" ") in the separator match zero or more whitespace
            A separator consisting only of spaces must match at least one
            whitespace.
        offset : int
            The offset (in bytes) from the file's current position. Defaults to 0.
            Only permitted for binary files.
            ..
            .. versionadded:: 1.17.0
${ARRAY_FUNCTION_LIKE}
            ..
            .. versionadded:: 1.20.0
        See also
        -----
        load, save
        ndarray.tofile
        loadtxt : More flexible way of loading data from a text file.
        Notes
        -----

```

```

1203: (4)          Do not rely on the combination of `tofile` and `fromfile` for
1204: (4)          data storage, as the binary files generated are not platform
1205: (4)          independent. In particular, no byte-order or data-type information is
1206: (4)          saved. Data can be stored in the platform independent ``.npy`` format
1207: (4)          using `save` and `load` instead.
1208: (4)          Examples
1209: (4)
1210: (4)          Construct an ndarray:
1211: (4)          >>> dt = np.dtype([('time', [(('min', np.int64), ('sec', np.int64))]),
1212: (4)                      ...                               ('temp', float)])
1213: (4)          >>> x = np.zeros((1,), dtype=dt)
1214: (4)          >>> x['time']['min'] = 10; x['temp'] = 98.25
1215: (4)          >>> x
1216: (4)          array([(10, 0), 98.25]),
1217: (10)          dtype=[('time', [('min', '<i8'), ('sec', '<i8')]), ('temp', '<f8')])
1218: (4)          Save the raw data to disk:
1219: (4)          >>> import tempfile
1220: (4)          >>> fname = tempfile.mkstemp()[1]
1221: (4)          >>> x.tofile(fname)
1222: (4)          Read the raw data from disk:
1223: (4)          >>> np.fromfile(fname, dtype=dt)
1224: (4)          array([(10, 0), 98.25]),
1225: (10)          dtype=[('time', [('min', '<i8'), ('sec', '<i8')]), ('temp', '<f8')])
1226: (4)          The recommended way to store and load data:
1227: (4)          >>> np.save(fname, x)
1228: (4)          >>> np.load(fname + '.npy')
1229: (4)          array([(10, 0), 98.25]),
1230: (10)          dtype=[('time', [('min', '<i8'), ('sec', '<i8')]), ('temp', '<f8')])
1231: (4)          """.replace(
1232: (8)              "${ARRAY_FUNCTION_LIKE}",
1233: (8)              array_function_like_doc,
1234: (4)          ))
1235: (0)          add_newdoc('numpy.core.multiarray', 'frombuffer',
1236: (4)          """
1237: (4)              frombuffer(buffer, dtype=float, count=-1, offset=0, *, like=None)
1238: (4)              Interpret a buffer as a 1-dimensional array.
1239: (4)              Parameters
1240: (4)
1241: (4)                  buffer : buffer_like
1242: (8)                      An object that exposes the buffer interface.
1243: (4)                  dtype : data-type, optional
1244: (8)                      Data-type of the returned array; default: float.
1245: (4)                  count : int, optional
1246: (8)                      Number of items to read. ``-1`` means all data in the buffer.
1247: (4)                  offset : int, optional
1248: (8)                      Start reading the buffer from this offset (in bytes); default: 0.
1249: (4)                  ${ARRAY_FUNCTION_LIKE}
1250: (8)                      .. versionadded:: 1.20.0
1251: (4)          Returns
1252: (4)
1253: (4)          out : ndarray
1254: (4)          See also
1255: (4)
1256: (4)          ndarray.tobytes
1257: (8)              Inverse of this operation, construct Python bytes from the raw data
1258: (8)              bytes in the array.
1259: (4)          Notes
1260: (4)
1261: (4)          If the buffer has data that is not in machine byte-order, this should
1262: (4)          be specified as part of the data-type, e.g.::
1263: (6)              >>> dt = np.dtype(int)
1264: (6)              >>> dt = dt.newbyteorder('>')
1265: (6)              >>> np.frombuffer(buf, dtype=dt) # doctest: +SKIP
1266: (4)          The data of the resulting array will not be byteswapped, but will be
1267: (4)          interpreted correctly.
1268: (4)          This function creates a view into the original object. This should be
safe
1269: (4)          in general, but it may make sense to copy the result when the original
1270: (4)          object is mutable or untrusted.

```

```

1271: (4)          Examples
1272: (4)          -----
1273: (4)          >>> s = b'hello world'
1274: (4)          >>> np.frombuffer(s, dtype='S1', count=5, offset=6)
1275: (4)          array([b'w', b'o', b'r', b'l', b'd'], dtype='|S1')
1276: (4)          >>> np.frombuffer(b'\x01\x02', dtype=np.uint8)

1316: (7)            transpose methods instead, e.g. ``arr.T.copy()``
1317: (4)          """")
1318: (0)        add_newdoc('numpy.core.multiarray', 'correlate',
1319: (4)          """cross_correlate(a,v, mode=0)""")
1320: (0)        add_newdoc('numpy.core.multiarray', 'arange',
1321: (4)          """
1322: (4)            arange([start,] stop[, step,], dtype=None, *, like=None)
1323: (4)            Return evenly spaced values within a given interval.
1324: (4)            ``arange`` can be called with a varying number of positional arguments:
1325: (4)            * ``arange(stop)``: Values are generated within the half-open interval
1326: (6)              ``[0, stop)`` (in other words, the interval including `start` but
1327: (6)              excluding `stop`).
1328: (4)            * ``arange(start, stop)``: Values are generated within the half-open
1329: (6)              interval ``[start, stop)``.
1330: (4)            * ``arange(start, stop, step)``: Values are generated within the half-open
1331: (6)              interval ``[start, stop)``, with spacing between values given by
1332: (6)              ``step``.
1333: (4)            For integer arguments the function is roughly equivalent to the Python
1334: (4)            built-in :py:class:`range`, but returns an ndarray rather than a ``range``
1335: (4)            instance.
1336: (4)            When using a non-integer step, such as 0.1, it is often better to use
1337: (4)              ``numpy.linspace``.

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1338: (4) See the Warning sections below for more information.
1339: (4) Parameters
1340: (4)
1341: (4) start : integer or real, optional
1342: (8) Start of interval. The interval includes this value. The default
1343: (8) start value is 0.
1344: (4) stop : integer or real
1345: (8) End of interval. The interval does not include this value, except
1346: (8) in some cases where `step` is not an integer and floating point
1347: (8) round-off affects the length of `out`.
1348: (4) step : integer or real, optional
1349: (8) Spacing between values. For any output `out`, this is the distance
1350: (8) between two adjacent values, ``out[i+1] - out[i]``. The default
1351: (8) step size is 1. If `step` is specified as a position argument,
1352: (8) `start` must also be given.
1353: (4) dtype : dtype, optional
1354: (8) The type of the output array. If `dtype` is not given, infer the data
1355: (8) type from the other input arguments.
1356: (4) ${ARRAY_FUNCTION_LIKE}
1357: (8) .. versionadded:: 1.20.0
1358: (4) Returns
1359: (4)
1360: (4) arange : ndarray
1361: (8) Array of evenly spaced values.
1362: (8) For floating point arguments, the length of the result is
1363: (8) ``ceil((stop - start)/step)``. Because of floating point overflow,
1364: (8) this rule may result in the last element of `out` being greater
1365: (8) than `stop`.
1366: (4) Warnings
1367: (4)
1368: (4) The length of the output might not be numerically stable.
1369: (4) Another stability issue is due to the internal implementation of
1370: (4) `numpy.arange`.
1371: (4) The actual step value used to populate the array is
1372: (4) ``dtype(start + step) - dtype(start)`` and not `step`. Precision loss
1373: (4) can occur here, due to casting or due to using floating points when
1374: (4) `start` is much larger than `step`. This can lead to unexpected
1375: (4) behaviour. For example::
1376: (6) >>> np.arange(0, 5, 0.5, dtype=int)
1377: (6) array([0, 0, 0, 0, 0, 0, 0, 0])
1378: (6) >>> np.arange(-3, 3, 0.5, dtype=int)
1379: (6) array([-3, -2, -1, 0, 1, 2, 3, 4, 5, 6, 7, 8])
1380: (4) In such cases, the use of `numpy.linspace` should be preferred.
1381: (4) The built-in :py:class:`range` generates :std:doc:`Python built-in
integers
1382: (4) integers
1383: (4) that have arbitrary size <python:c-api/long>, while `numpy.arange`
1384: (4) produces `numpy.int32` or `numpy.int64` numbers. This may result in
incorrect results for large integer values::
1385: (6) >>> power = 40
1386: (6) >>> modulo = 10000
1387: (6) >>> x1 = [(n ** power) % modulo for n in range(8)]
1388: (6) >>> x2 = [(n ** power) % modulo for n in np.arange(8)]
1389: (6) >>> print(x1)
1390: (6) [0, 1, 7776, 8801, 6176, 625, 6576, 4001] # correct
1391: (6) >>> print(x2)
1392: (6) [0, 1, 7776, 7185, 0, 5969, 4816, 3361] # incorrect

1425: (4)             """
1426: (0)           add_newdoc('numpy.core.multiarray', 'set_numeric_ops',
1427: (4)             """
1428: (4)               set_numeric_ops(op1=func1, op2=func2, ...)
1429: (4)               Set numerical operators for array objects.
1430: (4)               .. deprecated:: 1.16
1431: (8)                 For the general case, use :c:func:`PyUFunc.ReplaceLoopBySignature`.
1432: (8)                 For ndarray subclasses, define the ``__array_ufunc__`` method and
1433: (8)                 override the relevant ufunc.
1434: (4)             Parameters
1435: (4)             -----
1436: (4)               op1, op2, ... : callable
1437: (8)                 Each ``op = func`` pair describes an operator to be replaced.
1438: (8)                 For example, ``add = lambda x, y: np.add(x, y) % 5`` would replace
1439: (8)                 addition by modulus 5 addition.
1440: (4)             Returns
1441: (4)             -----
1442: (4)               saved_ops : list of callables
1443: (8)                 A list of all operators, stored before making replacements.
1444: (4)             Notes
1445: (4)             -----
1446: (4)               .. warning::
1447: (7)                 Use with care! Incorrect usage may lead to memory errors.
1448: (4)             A function replacing an operator cannot make use of that operator.
1449: (4)             For example, when replacing add, you may not use ``+``. Instead,
1450: (4)             directly call ufuncs.
1451: (4)             Examples
1452: (4)             -----
1453: (4)               >>> def add_mod5(x, y):
1454: (4)                 ...     return np.add(x, y) % 5
1455: (4)                 ...
1456: (4)               >>> old_funcs = np.set_numeric_ops(add=add_mod5)
1457: (4)               >>> x = np.arange(12).reshape((3, 4))
1458: (4)               >>> x + x
1459: (4)                 array([[0, 2, 4, 1],
1460: (11)                   [3, 0, 2, 4],
1461: (11)                   [1, 3, 0, 2]])
1462: (4)               >>> ignore = np.set_numeric_ops(**old_funcs) # restore operators
1463: (4)             """
1464: (0)           add_newdoc('numpy.core.multiarray', 'promote_types',
1465: (4)             """
1466: (4)               promote_types(type1, type2)
1467: (4)               Returns the data type with the smallest size and smallest scalar
1468: (4)               kind to which both ``type1`` and ``type2`` may be safely cast.
1469: (4)               The returned data type is always considered "canonical", this mainly
1470: (4)               means that the promoted dtype will always be in native byte order.
1471: (4)               This function is symmetric, but rarely associative.
1472: (4)             Parameters
1473: (4)             -----

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1474: (4) type1 : dtype or dtype specifier
1475: (8)     First data type.
1476: (4) type2 : dtype or dtype specifier
1477: (8)     Second data type.
1478: (4) Returns
1479: (4) -----
1480: (4) out : dtype
1481: (8)     The promoted data type.
1482: (4) Notes
1483: (4) -----
1484: (4) Please see `numpy.result_type` for additional information about promotion.
1485: (4) .. versionadded:: 1.6.0
1486: (4) Starting in NumPy 1.9, promote_types function now returns a valid string
1487: (4) length when given an integer or float dtype as one argument and a string
1488: (4) dtype as another argument. Previously it always returned the input string
1489: (4) dtype, even if it wasn't long enough to store the max integer/float value
1490: (4) converted to a string.
1491: (4) .. versionchanged:: 1.23.0
1492: (4) NumPy now supports promotion for more structured dtypes. It will now
1493: (4) remove unnecessary padding from a structure dtype and promote included
1494: (4) fields individually.
1495: (4) See Also
1496: (4) -----
1497: (4) result_type, dtype, can_cast
1498: (4) Examples
1499: (4) -----
1500: (4) >>> np.promote_types('f4', 'f8')
1501: (4) dtype('float64')
1502: (4) >>> np.promote_types('i8', 'f4')
1503: (4) dtype('float64')
1504: (4) >>> np.promote_types('>i8', '<c8')
1505: (4) dtype('complex128')
1506: (4) >>> np.promote_types('i4', 'S8')
1507: (4) dtype('S11')
1508: (4) An example of a non-associative case:
1509: (4) >>> p = np.promote_types
1510: (4) >>> p('S', p('i1', 'u1'))
1511: (4) dtype('S6')
1512: (4) >>> p(p('S', 'i1'), 'u1')
1513: (4) dtype('S4')
1514: (4) """
1515: (0) add_newdoc('numpy.core.multiarray', 'c_einsum',
1516: (4) """
1517: (4)     c_einsum(subscripts, *operands, out=None, dtype=None, order='K',
1518: (11)         casting='safe')
1519: (4)     *This documentation shadows that of the native python implementation of
the `einsum` function,
1520: (4)     except all references and examples related to the `optimize` argument (v
0.12.0) have been removed.*
1521: (4)     Evaluates the Einstein summation convention on the operands.
1522: (4)     Using the Einstein summation convention, many common multi-dimensional,
1523: (4)     linear algebraic array operations can be represented in a simple fashion.
1524: (4)     In *implicit* mode `einsum` computes these values.
1525: (4)     In *explicit* mode, `einsum` provides further flexibility to compute
1526: (4)     other array operations that might not be considered classical Einstein
1527: (4)     summation operations, by disabling, or forcing summation over specified
1528: (4)     subscript labels.
1529: (4)     See the notes and examples for clarification.
1530: (4) Parameters
1531: (4) -----
1532: (4) subscripts : str
1533: (8)     Specifies the subscripts for summation as comma separated list of
1534: (8)     subscript labels. An implicit (classical Einstein summation)
1535: (8)     calculation is performed unless the explicit indicator '->' is
1536: (8)     included as well as subscript labels of the precise output form.
1537: (4) operands : list of array_like
1538: (8)     These are the arrays for the operation.
1539: (4) out : ndarray, optional
1540: (8)     If provided, the calculation is done into this array.

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1541: (4)          dtype : {data-type, None}, optional
1542: (8)          If provided, forces the calculation to use the data type specified.
1543: (8)          Note that you may have to also give a more liberal `casting` parameter to allow the conversions. Default is None.
1544: (8)
1545: (4)          order : {'C', 'F', 'A', 'K'}, optional
1546: (8)          Controls the memory layout of the output. 'C' means it should be C contiguous. 'F' means it should be Fortran contiguous, 'A' means it should be 'F' if the inputs are all 'F', 'C' otherwise. 'K' means it should be as close to the layout of the inputs as is possible, including arbitrarily permuted axes.
1547: (8)          Default is 'K'.
1548: (8)
1549: (8)
1550: (8)
1551: (8)
1552: (4)          casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
1553: (8)          Controls what kind of data casting may occur. Setting this to 'unsafe' is not recommended, as it can adversely affect accumulations.
1554: (8)          * 'no' means the data types should not be cast at all.
1555: (10)         * 'equiv' means only byte-order changes are allowed.
1556: (10)         * 'safe' means only casts which can preserve values are allowed.
1557: (10)         * 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed.
1558: (10)
1559: (12)
1560: (10)
1561: (8)          * 'unsafe' means any data conversions may be done.
1562: (4)          Default is 'safe'.
1563: (8)          optimize : {False, True, 'greedy', 'optimal'}, optional
1564: (8)          Controls if intermediate optimization should occur. No optimization will occur if False and True will default to the 'greedy' algorithm.
1565: (8)          Also accepts an explicit contraction list from the ``np.einsum_path`` function. See ``np.einsum_path`` for more details. Defaults to False.
1566: (8)
1567: (4)          Returns
1568: (4)          -----
1569: (4)          output : ndarray
1570: (8)          The calculation based on the Einstein summation convention.
1571: (4)          See Also
1572: (4)          -----
1573: (4)          einsum_path, dot, inner, outer, tensordot, linalg.multi_dot
1574: (4)
1575: (4)
1576: (4)          .. versionadded:: 1.6.0
1577: (4)          The Einstein summation convention can be used to compute many multi-dimensional, linear algebraic array operations. `einsum` provides a succinct way of representing these.
1578: (4)          A non-exhaustive list of these operations,
1579: (4)          which can be computed by `einsum`, is shown below along with examples:
1580: (4)          * Trace of an array, :py:func:`numpy.trace`.
1581: (4)          * Return a diagonal, :py:func:`numpy.diag`.
1582: (4)          * Array axis summations, :py:func:`numpy.sum`.
1583: (4)          * Transpositions and permutations, :py:func:`numpy.transpose`.
1584: (4)          * Matrix multiplication and dot product, :py:func:`numpy.matmul`.
1585: (4)          * Vector inner and outer products, :py:func:`numpy.inner`.
1586: (4)          * Broadcasting, element-wise and scalar multiplication, :py:func:`numpy.multiply`.
1587: (4)          * Tensor contractions, :py:func:`numpy.tensordot`.
1588: (4)          * Chained array operations, in efficient calculation order, :py:func:`numpy.einsum_path`.
1589: (4)
1590: (4)
1591: (4)          The subscripts string is a comma-separated list of subscript labels, where each label refers to a dimension of the corresponding operand.
1592: (4)          Whenever a label is repeated it is summed, so ``np.einsum('i,i', a, b)`` is equivalent to :py:func:`np.inner(a,b) <numpy.inner>`. If a label appears only once, it is not summed, so ``np.einsum('i', a)`` produces a view of ``a`` with no changes. A further example ``np.einsum('ij,jk', a, b)``
1593: (4)
1594: (4)
1595: (4)
1596: (4)
1597: (4)
1598: (4)
1599: (4)
equivalent
1600: (4)          describes traditional matrix multiplication and is equivalent to :py:func:`np.matmul(a,b) <numpy.matmul>`. Repeated subscript labels in one operand take the diagonal. For example, ``np.einsum('ii', a)`` is
1601: (4)          to :py:func:`np.trace(a) <numpy.trace>`.
1602: (4)          In *implicit mode*, the chosen subscripts are important since the axes of the output are reordered alphabetically. This means that ``np.einsum('ij', a)`` doesn't affect a 2D array, while
1603: (4)

```

```

1604: (4) ``np.einsum('ji', a)`` takes its transpose. Additionally,
1605: (4) ``np.einsum('ij,jk', a, b)`` returns a matrix multiplication, while,
1606: (4) ``np.einsum('ij,jh', a, b)`` returns the transpose of the
1607: (4) multiplication since subscript 'h' precedes subscript 'i'.
1608: (4) In *explicit mode* the output can be directly controlled by
1609: (4) specifying output subscript labels. This requires the
1610: (4) identifier ' $\rightarrow$ ' as well as the list of output subscript labels.
1611: (4) This feature increases the flexibility of the function since
1612: (4) summing can be disabled or forced when required. The call
1613: (4) ``np.einsum('i->', a)`` is like :py:func:`np.sum(a, axis=-1)` <numpy.sum>,
1614: (4) and ``np.einsum('ii->i', a)`` is like :py:func:`np.diag(a)` <numpy.diag>.
1615: (4) The difference is that `einsum` does not allow broadcasting by default.
1616: (4) Additionally ``np.einsum('ij,jh->ih', a, b)`` directly specifies the
1617: (4) order of the output subscript labels and therefore returns matrix
1618: (4) multiplication, unlike the example above in implicit mode.
1619: (4) To enable and control broadcasting, use an ellipsis. Default
1620: (4) NumPy-style broadcasting is done by adding an ellipsis
1621: (4) to the left of each term, like ``np.einsum('...ii->...i', a)``.
1622: (4) To take the trace along the first and last axes,
1623: (4) you can do ``np.einsum('i...i', a)``, or to do a matrix-matrix
1624: (4) product with the left-most indices instead of rightmost, one can do
1625: (4) ``np.einsum('ij...,jk....>ik...', a, b)``.
1626: (4) When there is only one operand, no axes are summed, and no output
1627: (4) parameter is provided, a view into the operand is returned instead
1628: (4) of a new array. Thus, taking the diagonal as ``np.einsum('ii->i', a)``
1629: (4) produces a view (changed in version 1.10.0).
1630: (4) `einsum` also provides an alternative way to provide the subscripts
1631: (4) and operands as ``einsum(op0, sublist0, op1, sublist1, ...,
[sublistout])``.

1632: (4) If the output shape is not provided in this format `einsum` will be
1633: (4) calculated in implicit mode, otherwise it will be performed explicitly.
1634: (4) The examples below have corresponding `einsum` calls with the two
1635: (4) parameter methods.
1636: (4) .. versionadded:: 1.10.0
1637: (4) Views returned from einsum are now writeable whenever the input array
1638: (4) is writeable. For example, ``np.einsum('ijk...->kji...', a)`` will now
1639: (4) have the same effect as :py:func:`np.swapaxes(a, 0, 2)` <numpy.swapaxes>
1640: (4) and ``np.einsum('ii->i', a)`` will return a writeable view of the diagonal
1641: (4) of a 2D array.
1642: (4) Examples
1643: (4) -----
1644: (4) >>> a = np.arange(25).reshape(5,5)
1645: (4) >>> b = np.arange(5)
1646: (4) >>> c = np.arange(6).reshape(2,3)
1647: (4) Trace of a matrix:
1648: (4) >>> np.einsum('ii', a)
1649: (4) 60
1650: (4) >>> np.einsum(a, [0,0])
1651: (4) 60
1652: (4) >>> np.trace(a)
1653: (4) 60
1654: (4) Extract the diagonal (requires explicit form):
1655: (4) >>> np.einsum('ii->i', a)
1656: (4) array([ 0,  6, 12, 18, 24])
1657: (4) >>> np.einsum(a, [0,0], [0])
1658: (4) array([ 0,  6, 12, 18, 24])
1659: (4) >>> np.diag(a)
1660: (4) array([ 0,  6, 12, 18, 24])
1661: (4) Sum over an axis (requires explicit form):
1662: (4) >>> np.einsum('ij->i', a)
1663: (4) array([ 10,  35,  60,  85, 110])
1664: (4) >>> np.einsum(a, [0,1], [0])
1665: (4) array([ 10,  35,  60,  85, 110])
1666: (4) >>> np.sum(a, axis=1)
1667: (4) array([ 10,  35,  60,  85, 110])
1668: (4) For higher dimensional arrays summing a single axis can be done with
ellipsis:
1669: (4) >>> np.einsum('...j->...', a)
1670: (4) array([ 10,  35,  60,  85, 110])

```

```

1671: (4)          >>> np.einsum(a, [Ellipsis,1], [Ellipsis])
1672: (4)          array([ 10,  35,  60,  85, 110])
1673: (4)          Compute a matrix transpose, or reorder any number of axes:
1674: (4)          >>> np.einsum('ji', c)
1675: (4)          array([[0, 3],
1676: (11)             [1, 4],
1677: (11)             [2, 5]])
1678: (4)          >>> np.einsum('ij->ji', c)
1679: (4)          array([[0, 3],
1680: (11)             [1, 4],
1681: (11)             [2, 5]])
1682: (4)          >>> np.einsum(c, [1,0])
1683: (4)          array([[0, 3],
1684: (11)             [1, 4],
1685: (11)             [2, 5]])
1686: (4)          >>> np.transpose(c)
1687: (4)          array([[0, 3],
1688: (11)             [1, 4],
1689: (11)             [2, 5]])
1690: (4)          Vector inner products:
1691: (4)          >>> np.einsum('i,i', b, b)
1692: (4)          30
1693: (4)          >>> np.einsum(b, [0], b, [0])
1694: (4)          30
1695: (4)          >>> np.inner(b,b)
1696: (4)          30
1697: (4)          Matrix vector multiplication:
1698: (4)          >>> np.einsum('ij,j', a, b)
1699: (4)          array([ 30,  80, 130, 180, 230])
1700: (4)          >>> np.einsum(a, [0,1], b, [1])
1701: (4)          array([ 30,  80, 130, 180, 230])
1702: (4)          >>> np.dot(a, b)
1703: (4)          array([ 30,  80, 130, 180, 230])
1704: (4)          >>> np.einsum('...j,j', a, b)
1705: (4)          array([ 30,  80, 130, 180, 230])
1706: (4)          Broadcasting and scalar multiplication:
1707: (4)          >>> np.einsum('..., ...', 3, c)
1708: (4)          array([[ 0,  3,  6],
1709: (11)             [ 9, 12, 15]])
1710: (4)          >>> np.einsum(',ij', 3, c)
1711: (4)          array([[ 0,  3,  6],
1712: (11)             [ 9, 12, 15]])
1713: (4)          >>> np.einsum(3, [Ellipsis], c, [Ellipsis])
1714: (4)          array([[ 0,  3,  6],
1715: (11)             [ 9, 12, 15]])
1716: (4)          >>> np.multiply(3, c)
1717: (4)          array([[ 0,  3,  6],
1718: (11)             [ 9, 12, 15]])
1719: (4)          Vector outer product:
1720: (4)          >>> np.einsum('i,j', np.arange(2)+1, b)
1721: (4)          array([[ 0,  1,  2,  3,  4],
1722: (11)             [ 0,  2,  4,  6,  8]])
1723: (4)          >>> np.einsum(np.arange(2)+1, [0], b, [1])
1724: (4)          array([[ 0,  1,  2,  3,  4],
1725: (11)             [ 0,  2,  4,  6,  8]])
1726: (4)          >>> np.outer(np.arange(2)+1, b)
1727: (4)          array([[ 0,  1,  2,  3,  4],
1728: (11)             [ 0,  2,  4,  6,  8]])
1729: (4)          Tensor contraction:
1730: (4)          >>> a = np.arange(60.).reshape(3,4,5)
1731: (4)          >>> b = np.arange(24.).reshape(4,3,2)
1732: (4)          >>> np.einsum('ijk,jil->kl', a, b)
1733: (4)          array([[ 4400.,   4730.],
1734: (11)             [ 4532.,   4874.],
1735: (11)             [ 4664.,   5018.],
1736: (11)             [ 4796.,   5162.],
1737: (11)             [ 4928.,   5306.]])
1738: (4)          >>> np.einsum(a, [0,1,2], b, [1,0,3], [2,3])
1739: (4)          array([[ 4400.,   4730.],

```

```

1740: (11) [ 4532., 4874.],
1741: (11) [ 4664., 5018.],
1742: (11) [ 4796., 5162.],
1743: (11) [ 4928., 5306.]])
1744: (4) >>> np.tensordot(a,b, axes=([1,0],[0,1]))
1745: (4) array([[ 4400., 4730.],
1746: (11) [ 4532., 4874.],
1747: (11) [ 4664., 5018.],
1748: (11) [ 4796., 5162.],
1749: (11) [ 4928., 5306.]])
1750: (4) Writeable returned arrays (since version 1.10.0):
1751: (4) >>> a = np.zeros((3, 3))
1752: (4) >>> np.einsum('ii->i', a)[:] = 1
1753: (4) >>> a
1754: (4) array([[ 1., 0., 0.],
1755: (11) [ 0., 1., 0.],
1756: (11) [ 0., 0., 1.]])
1757: (4) Example of ellipsis use:
1758: (4) >>> a = np.arange(6).reshape((3,2))
1759: (4) >>> b = np.arange(12).reshape((4,3))
1760: (4) >>> np.einsum('ki,jk->ij', a, b)
1761: (4) array([[10, 28, 46, 64],
1762: (11) [13, 40, 67, 94]])
1763: (4) >>> np.einsum('ki,...k->i...', a, b)
1764: (4) array([[10, 28, 46, 64],
1765: (11) [13, 40, 67, 94]])
1766: (4) >>> np.einsum('k...,jk', a, b)
1767: (4) array([[10, 28, 46, 64],
1768: (11) [13, 40, 67, 94]])
1769: (4) """
1770: (0) add_newdoc('numpy.core.multiarray', 'ndarray',
1771: (4) """
1772: (4) ndarray(shape, dtype=float, buffer=None, offset=0,
1773: (12) strides=None, order=None)
1774: (4) An array object represents a multidimensional, homogeneous array
1775: (4) of fixed-size items. An associated data-type object describes the
1776: (4) format of each element in the array (its byte-order, how many bytes it
1777: (4) occupies in memory, whether it is an integer, a floating point number,
1778: (4) or something else, etc.)
1779: (4) Arrays should be constructed using `array`, `zeros` or `empty` (refer
1780: (4) to the See Also section below). The parameters given here refer to
1781: (4) a low-level method (`ndarray(...)`) for instantiating an array.
1782: (4) For more information, refer to the `numpy` module and examine the
1783: (4) methods and attributes of an array.
1784: (4) Parameters
1785: (4) -----
1786: (4) (for the __new__ method; see Notes below)
1787: (4) shape : tuple of ints
1788: (8) Shape of created array.
1789: (4) dtype : data-type, optional
1790: (8) Any object that can be interpreted as a numpy data type.
1791: (4) buffer : object exposing buffer interface, optional
1792: (8) Used to fill the array with data.
1793: (4) offset : int, optional
1794: (8) Offset of array data in buffer.
1795: (4) strides : tuple of ints, optional
1796: (8) Strides of data in memory.
1797: (4) order : {'C', 'F'}, optional
1798: (8) Row-major (C-style) or column-major (Fortran-style) order.
1799: (4) Attributes
1800: (4) -----
1801: (4) T : ndarray
1802: (8) Transpose of the array.
1803: (4) data : buffer
1804: (8) The array's elements, in memory.
1805: (4) dtype : dtype object
1806: (8) Describes the format of the elements in the array.
1807: (4) flags : dict
1808: (8) Dictionary containing information related to memory use, e.g.,

```

```

1809: (8)           'C_CONTIGUOUS', 'OWNDATA', 'WRITEABLE', etc.
1810: (4)           flat : numpy.flatiter object
1811: (8)           Flattened version of the array as an iterator. The iterator
1812: (8)           allows assignments, e.g., ``x.flat = 3`` (See `ndarray.flat` for
1813: (8)           assignment examples; TODO).
1814: (4)           imag : ndarray
1815: (8)           Imaginary part of the array.
1816: (4)           real : ndarray
1817: (8)           Real part of the array.
1818: (4)           size : int
1819: (8)           Number of elements in the array.
1820: (4)           itemsize : int
1821: (8)           The memory use of each array element in bytes.
1822: (4)           nbytes : int
1823: (8)           The total number of bytes required to store the array data,
1824: (8)           i.e., ``itemsize * size``.
1825: (4)           ndim : int
1826: (8)           The array's number of dimensions.
1827: (4)           shape : tuple of ints
1828: (8)           Shape of the array.
1829: (4)           strides : tuple of ints
1830: (8)           The step-size required to move from one element to the next in
1831: (8)           memory. For example, a contiguous ``(3, 4)`` array of type
1832: (8)           ``int16`` in C-order has strides ``(8, 2)``. This implies that
1833: (8)           to move from element to element in memory requires jumps of 2 bytes.
1834: (8)           To move from row-to-row, one needs to jump 8 bytes at a time
1835: (8)           (``2 * 4``).
1836: (4)           ctypes : ctypes object
1837: (8)           Class containing properties of the array needed for interaction
1838: (8)           with ctypes.
1839: (4)           base : ndarray
1840: (8)           If the array is a view into another array, that array is its `base`
1841: (8)           (unless that array is also a view). The `base` array is where the
1842: (8)           array data is actually stored.
1843: (4)           See Also
1844: (4)           -----
1845: (4)           array : Construct an array.
1846: (4)           zeros : Create an array, each element of which is zero.
1847: (4)           empty : Create an array, but leave its allocated memory unchanged (i.e.,
1848: (12)             it contains "garbage").
1849: (4)           dtype : Create a data-type.
1850: (4)           numpy.typing.NDArray : An ndarray alias :term:`generic <generic type>`  

1851: (27)             w.r.t. its `dtype.type <numpy.dtype.type>`.
1852: (4)           Notes
1853: (4)           -----
1854: (4)           There are two modes of creating an array using ``__new__``:
1855: (4)           1. If `buffer` is None, then only `shape`, `dtype`, and `order`
1856: (7)             are used.
1857: (4)           2. If `buffer` is an object exposing the buffer interface, then
1858: (7)             all keywords are interpreted.
1859: (4)           No ``__init__`` method is needed because the array is fully initialized
1860: (4)             after the ``__new__`` method.
1861: (4)           Examples
1862: (4)           -----
1863: (4)           These examples illustrate the low-level `ndarray` constructor. Refer
1864: (4)             to the `See Also` section above for easier ways of constructing an
1865: (4)             ndarray.
1866: (4)           First mode, `buffer` is None:
1867: (4)           >>> np.ndarray(shape=(2,2), dtype=float, order='F')
1868: (4)           array([[0.0e+000, 0.0e+000], # random
1869: (11)             [      nan, 2.5e-323]])
1870: (4)           Second mode:
1871: (4)           >>> np.ndarray((2,), buffer=np.array([1,2,3]),
1872: (4)             ...          offset=np.int_().itemsize,
1873: (4)             ...          dtype=int) # offset = 1*itemsize, i.e. skip first element
1874: (4)             array([2, 3])
1875: (4)             """)
1876: (0)             add_newdoc('numpy.core.multiarray', 'ndarray', ('__array_interface__',
1877: (4)               """Array protocol: Python side."""))
```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1878: (0) add_newdoc('numpy.core.multiarray', 'ndarray', ('__array_priority__',
1879: (4)     """Array priority."""))
1880: (0) add_newdoc('numpy.core.multiarray', 'ndarray', ('__array_struct__',
1881: (4)     """Array protocol: C-struct side.""))
1882: (0) add_newdoc('numpy.core.multiarray', 'ndarray', ('__dlpack__',
1883: (4)     """a.__dlpack__(*, stream=None)
1884: (4)         DLPack Protocol: Part of the Array API.""))
1885: (0) add_newdoc('numpy.core.multiarray', 'ndarray', ('__dlpack_device__',
1886: (4)     """a.__dlpack_device__()
1887: (4)         DLPack Protocol: Part of the Array API.""))
1888: (0) add_newdoc('numpy.core.multiarray', 'ndarray', ('base',
1889: (4)     """
1890: (4)         Base object if memory is from some other object.
1891: (4)     Examples
1892: (4)     -----
1893: (4)     The base of an array that owns its memory is None:
1894: (4)     >>> x = np.array([1,2,3,4])
1895: (4)     >>> x.base is None
1896: (4)     True
1897: (4)     Slicing creates a view, whose memory is shared with x:
1898: (4)     >>> y = x[2:]
1899: (4)     >>> y.base is x
1900: (4)     True
1901: (4)     """
1902: (0) add_newdoc('numpy.core.multiarray', 'ndarray', ('ctypes',
1903: (4)     """
1904: (4)         An object to simplify the interaction of the array with the ctypes
1905: (4)         module.
1906: (4)         This attribute creates an object that makes it easier to use arrays
1907: (4)         when calling shared libraries with the ctypes module. The returned
1908: (4)         object has, among others, data, shape, and strides attributes (see
1909: (4)         Notes below) which themselves return ctypes objects that can be used
1910: (4)         as arguments to a shared library.
1911: (4)     Parameters
1912: (4)     -----
1913: (4)     None
1914: (4)     Returns
1915: (4)     -----
1916: (4)     c : Python object
1917: (8)     Possessing attributes data, shape, strides, etc.
1918: (4)     See Also
1919: (4)     -----
1920: (4)     numpy.ctypeslib
1921: (4)     Notes
1922: (4)     -----
1923: (4)     Below are the public attributes of this object which were documented
1924: (4)     in "Guide to NumPy" (we have omitted undocumented public attributes,
1925: (4)     as well as documented private attributes):
1926: (4)     .. autoattribute:: numpy.core._internal._ctypes.data
1927: (8)     :noindex:
1928: (4)     .. autoattribute:: numpy.core._internal._ctypes.shape
1929: (8)     :noindex:
1930: (4)     .. autoattribute:: numpy.core._internal._ctypes.strides
1931: (8)     :noindex:
1932: (4)     .. automethod:: numpy.core._internal._ctypes.data_as
1933: (8)     :noindex:
1934: (4)     .. automethod:: numpy.core._internal._ctypes.shape_as
1935: (8)     :noindex:
1936: (4)     .. automethod:: numpy.core._internal._ctypes.strides_as
1937: (8)     :noindex:
1938: (4)     If the ctypes module is not available, then the ctypes attribute
1939: (4)     of array objects still returns something useful, but ctypes objects
1940: (4)     are not returned and errors may be raised instead. In particular,
1941: (4)     the object will still have the ``as_parameter`` attribute which will
1942: (4)     return an integer equal to the data attribute.
1943: (4)     Examples
1944: (4)     -----
1945: (4)     >>> import ctypes
1946: (4)     >>> x = np.array([[0, 1], [2, 3]], dtype=np.int32)

```

```

2015: (4)      """"))
2016: (0)      add_newdoc('numpy.core.multiarray', 'ndarray', ('flags',
2017: (4)          """
2018: (4)              Information about the memory layout of the array.
2019: (4)              Attributes
2020: (4)              -----
2021: (4)              C_CONTIGUOUS (C)
2022: (8)                  The data is in a single, C-style contiguous segment.
2023: (4)              F_CONTIGUOUS (F)
2024: (8)                  The data is in a single, Fortran-style contiguous segment.
2025: (4)              OWNDATA (O)
2026: (8)                  The array owns the memory it uses or borrows it from another object.
2027: (4)              WRITEABLE (W)
2028: (8)                  The data area can be written to. Setting this to False locks
2029: (8)                      the data, making it read-only. A view (slice, etc.) inherits
2030: (8)                          from its base array at creation time, but a view of a writeable
2031: (8)                          array may be subsequently locked while the base array remains
2032: (8)      (The opposite is not true, in that a view of a locked array may not
2033: (8)      be made writeable. However, currently, locking a base object does not
2034: (8)      lock any views that already reference it, so under that circumstance
2035: (8)          is possible to alter the contents of a locked array via a previously
2036: (8)          created writeable view onto it.) Attempting to change a non-writeable
2037: (8)          array raises a RuntimeError exception.
2038: (4)      ALIGNED (A)
2039: (8)          The data and all elements are aligned appropriately for the hardware.
2040: (4)      WRITEBACKIFCOPY (X)
2041: (8)          This array is a copy of some other array. The C-API function
2042: (8)          PyArray_ResolveWritebackIfCopy must be called before deallocated
2043: (8)          to the base array will be updated with the contents of this array.
2044: (4)      FNC
2045: (8)          F_CONTIGUOUS and not C_CONTIGUOUS.
2046: (4)      FORC
2047: (8)          F_CONTIGUOUS or C_CONTIGUOUS (one-segment test).
2048: (4)      BEHAVED (B)
2049: (8)          ALIGNED and WRITEABLE.
2050: (4)      CARRAY (CA)
2051: (8)          BEHAVED and C_CONTIGUOUS.
2052: (4)      FARRAY (FA)
2053: (8)          BEHAVED and F_CONTIGUOUS and not C_CONTIGUOUS.
2054: (4)      Notes
2055: (4)      -----
2056: (4)          The `flags` object can be accessed dictionary-like (as in
``a.flags['WRITEABLE']`),
2057: (4)          or by using lowercased attribute names (as in ``a.flags.writeable``).
2058: (4)          names are only supported in dictionary access.
2059: (4)          Only the WRITEBACKIFCOPY, WRITEABLE, and ALIGNED flags can be
2060: (4)          changed by the user, via direct assignment to the attribute or dictionary
2061: (4)          entry, or by calling `ndarray.setflags`.
2062: (4)          The array flags cannot be set arbitrarily:
2063: (4)          - WRITEBACKIFCOPY can only be set ``False``.
2064: (4)          - ALIGNED can only be set ``True`` if the data is truly aligned.
2065: (4)          - WRITEABLE can only be set ``True`` if the array owns its own memory
2066: (6)          or the ultimate owner of the memory exposes a writeable buffer
2067: (6)          interface or is a string.
2068: (4)          Arrays can be both C-style and Fortran-style contiguous simultaneously.
2069: (4)          This is clear for 1-dimensional arrays, but can also be true for higher
2070: (4)          dimensional arrays.
2071: (4)          Even for contiguous arrays a stride for a given dimension
2072: (4)          ``arr.strides[dim]`` may be *arbitrary* if ``arr.shape[dim] == 1``
2073: (4)          or the array has no elements.
2074: (4)          It does *not* generally hold that ``self.strides[-1] == self.itemsize``
2075: (4)          for C-style contiguous arrays or ``self.strides[0] == self.itemsize`` for
2076: (4)          Fortran-style contiguous arrays is true.
2077: (4)          """

2197: (0)      add_newdoc('numpy.core.multiarray', 'ndarray', ('size',
2198: (4)          """
2199: (4)          Number of elements in the array.
2200: (4)          Equal to ``np.prod(a.shape)``, i.e., the product of the array's
2201: (4)          dimensions.
2202: (4)          Notes
2203: (4)          -----
2204: (4)          `a.size` returns a standard arbitrary precision Python integer. This
2205: (4)          may not be the case with other methods of obtaining the same value
2206: (4)          (like the suggested ``np.prod(a.shape)``, which returns an instance
2207: (4)          of ``np.int_``), and may be relevant if the value is used further in
2208: (4)          calculations that may overflow a fixed size integer type.
2209: (4)          Examples
2210: (4)          -----
2211: (4)          >>> x = np.zeros((3, 5, 2), dtype=np.complex128)
2212: (4)          >>> x.size
2213: (4)          30
2214: (4)          >>> np.prod(x.shape)
2215: (4)          30
2216: (4)          """

add_newdoc('numpy.core.multiarray', 'ndarray', ('strides',
        """
        Tuple of bytes to step in each dimension when traversing an array.
        The byte offset of element ``(i[0], i[1], ..., i[n])`` in an array `a` is::
            offset = sum(np.array(i) * a.strides)
        A more detailed explanation of strides can be found in the
        "ndarray.rst" file in the NumPy reference guide.
        .. warning::
            Setting ``arr.strides`` is discouraged and may be deprecated in the
            future. ``numpy.lib.stride_tricks.as_strided`` should be preferred
            to create a new view of the same data in a safer way.
    Notes
    -----
    Imagine an array of 32-bit integers (each 4 bytes)::

        x = np.array([[0, 1, 2, 3, 4],
                     [5, 6, 7, 8, 9]], dtype=np.int32)
    This array is stored in memory as 40 bytes, one after the other
    (known as a contiguous block of memory). The strides of an array tell
    us how many bytes we have to skip in memory to move to the next position
    along a certain axis. For example, we have to skip 4 bytes (1 value) to
    move to the next column, but 20 bytes (5 values) to get to the same
    position in the next row. As such, the strides for the array `x` will be
    ``(20, 4)``.
    See Also
    -----
    numpy.lib.stride_tricks.as_strided
    Examples
    -----
    >>> y = np.reshape(np.arange(2*3*4), (2,3,4))
    >>> y
    array([[[ 0,  1,  2,  3],
           [ 4,  5,  6,  7],
           [ 8,  9, 10, 11]],
          [[12, 13, 14, 15],
           [16, 17, 18, 19],
           [20, 21, 22, 23]]])
    >>> y.strides
    (48, 16, 4)
    >>> y[1,1,1]
    17
    >>> offset=sum(y.strides * np.array((1,1,1)))
    >>> offset/y.itemsize
    17
    >>> x = np.reshape(np.arange(5*6*7*8), (5,6,7,8)).transpose(2,3,1,0)
    >>> x.strides
    (32, 4, 224, 1344)

2420: (4)           dtype : str or dtype
2421: (8)           Typecode or data-type to which the array is cast.

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

2422: (4)          order : {'C', 'F', 'A', 'K'}, optional
2423: (8)          Controls the memory layout order of the result.
2424: (8)          'C' means C order, 'F' means Fortran order, 'A'
2425: (8)          means 'F' order if all the arrays are Fortran contiguous,
2426: (8)          'C' order otherwise, and 'K' means as close to the
2427: (8)          order the array elements appear in memory as possible.
2428: (8)          Default is 'K'.
2429: (4)          casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
2430: (8)          Controls what kind of data casting may occur. Defaults to 'unsafe'
2431: (8)          for backwards compatibility.
2432: (10)         * 'no' means the data types should not be cast at all.
2433: (10)         * 'equiv' means only byte-order changes are allowed.
2434: (10)         * 'safe' means only casts which can preserve values are allowed.
2435: (10)         * 'same_kind' means only safe casts or casts within a kind,
2436: (12)          like float64 to float32, are allowed.
2437: (10)         * 'unsafe' means any data conversions may be done.
2438: (4)          subok : bool, optional
2439: (8)          If True, then sub-classes will be passed-through (default), otherwise
2440: (8)          the returned array will be forced to be a base-class array.
2441: (4)          copy : bool, optional
2442: (8)          By default, astype always returns a newly allocated array. If this
2443: (8)          is set to false, and the `dtype`, `order`, and `subok`
2444: (8)          requirements are satisfied, the input array is returned instead
2445: (8)          of a copy.
2446: (4)          Returns
2447: (4)          -----
2448: (4)          arr_t : ndarray
2449: (8)          Unless `copy` is False and the other conditions for returning the
input
2450: (8)          array are satisfied (see description for `copy` input parameter),
`arr_t`
2451: (8)          is a new array of the same shape as the input array, with dtype, order
2452: (8)          given by `dtype`, `order`.
2453: (4)          Notes
2454: (4)          -----
2455: (4)          .. versionchanged:: 1.17.0
2456: (7)          Casting between a simple data type and a structured one is possible
only
2457: (7)          for "unsafe" casting. Casting to multiple fields is allowed, but
2458: (7)          casting from multiple fields is not.
2459: (4)          .. versionchanged:: 1.9.0
2460: (7)          Casting from numeric to string types in 'safe' casting mode requires
2461: (7)          that the string dtype length is long enough to store the max
2462: (7)          integer/float value converted.
2463: (4)          Raises
2464: (4)          -----
2465: (4)          ComplexWarning
2466: (8)          When casting from complex to float or int. To avoid this,
2467: (8)          one should use ``a.real.astype(t)``.
2468: (4)          Examples
2469: (4)          -----
2470: (4)          >>> x = np.array([1, 2, 2.5])
2471: (4)          >>> x
2472: (4)          array([1., 2., 2.5])
2473: (4)          >>> x.astype(int)
2474: (4)          array([1, 2, 2])
2475: (4)          "''")
2476: (0)          add_newdoc('numpy.core.multiarray', 'ndarray', ('byteswap',
2477: (4)          """"
2478: (4)          a.byteswap(inplace=False)
2479: (4)          Swap the bytes of the array elements
2480: (4)          Toggle between low-endian and big-endian data representation by
2481: (4)          returning a byteswapped array, optionally swapped in-place.
2482: (4)          Arrays of byte-strings are not swapped. The real and imaginary
2483: (4)          parts of a complex number are swapped individually.
2484: (4)          Parameters
2485: (4)          -----
2486: (4)          inplace : bool, optional
2487: (8)          If ``True``, swap bytes in-place, default is ``False``.

```

```

2488: (4)          Returns
2489: (4)          -----
2490: (4)          out : ndarray
2491: (8)          The byteswapped array. If `inplace` is ``True``, this is
2492: (8)          a view to self.
2493: (4)          Examples
2494: (4)          -----
2495: (4)          >>> A = np.array([1, 256, 8755], dtype=np.int16)
2496: (4)          >>> list(map(hex, A))
2497: (4)          ['0x1', '0x100', '0x2233']
2498: (4)          >>> A.byteswap(inplace=True)
2499: (4)          array([ 256,      1, 13090], dtype=int16)
2500: (4)          >>> list(map(hex, A))
2501: (4)          ['0x100', '0x1', '0x3322']
2502: (4)          Arrays of byte-strings are not swapped
2503: (4)          >>> A = np.array([b'ceg', b'fac'])
2504: (4)          >>> A.byteswap()
2505: (4)          array([b'ceg', b'fac'], dtype='|S3')
2506: (4)          ``A.newbyteorder().byteswap()`` produces an array with the same values
2507: (6)          but different representation in memory
2508: (4)          >>> A = np.array([1, 2, 3])
2509: (4)          >>> A.view(np.uint8)
2510: (4)          array([1, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 3, 0, 0, 0, 0, 0,
2511: (11)          0, 0], dtype=uint8)
2512: (4)          >>> A.newbyteorder().byteswap(inplace=True)
2513: (4)          array([1, 2, 3])
2514: (4)          >>> A.view(np.uint8)
2515: (4)          array([0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0,
2516: (11)          0, 3], dtype=uint8)
2517: (4)          """))

2524: (4)          -----
2525: (4)          numpy.choose : equivalent function
2526: (4)          """
2527: (0)          add_newdoc('numpy.core.multiarray', 'ndarray', ('clip',
2528: (4)          """
2529: (4)          a.clip(min=None, max=None, out=None, **kwargs)
2530: (4)          Return an array whose values are limited to ``[min, max]``.
2531: (4)          One of max or min must be given.
2532: (4)          Refer to `numpy.clip` for full documentation.
2533: (4)          See Also
2534: (4)          -----
2535: (4)          numpy.clip : equivalent function
2536: (4)          """
2537: (0)          add_newdoc('numpy.core.multiarray', 'ndarray', ('compress',
2538: (4)          """
2539: (4)          a.compress(condition, axis=None, out=None)
2540: (4)          Return selected slices of this array along given axis.
2541: (4)          Refer to `numpy.compress` for full documentation.
2542: (4)          See Also
2543: (4)          -----
2544: (4)          numpy.compress : equivalent function
2545: (4)          """
2546: (0)          add_newdoc('numpy.core.multiarray', 'ndarray', ('conj',
2547: (4)          """
2548: (4)          a.conj()
2549: (4)          Complex-conjugate all elements.
2550: (4)          Refer to `numpy.conjugate` for full documentation.
2551: (4)          See Also
2552: (4)          -----
2553: (4)          numpy.conjugate : equivalent function
2554: (4)          """
2555: (0)          add_newdoc('numpy.core.multiarray', 'ndarray', ('conjugate',
2556: (4)          """

```

```

2557: (4)           a.conjugate()
2558: (4)           Return the complex conjugate, element-wise.
2559: (4)           Refer to `numpy.conjugate` for full documentation.
2560: (4)           See Also
2561: (4)           -----
2562: (4)           numpy.conjugate : equivalent function
2563: (4)           """
2564: (0)           add_newdoc('numpy.core.multiarray', 'ndarray', ('copy',
2565: (4)           """
2566: (4)           a.copy(order='C')
2567: (4)           Return a copy of the array.
2568: (4)           Parameters
2569: (4)           -----
2570: (4)           order : {'C', 'F', 'A', 'K'}, optional
2571: (8)           Controls the memory layout of the copy. 'C' means C-order,
2572: (8)           'F' means F-order, 'A' means 'F' if `a` is Fortran contiguous,
2573: (8)           'C' otherwise. 'K' means match the layout of `a` as closely
2574: (8)           as possible. (Note that this function and :func:`numpy.copy` are very
2575: (8)           similar but have different default values for their order=
2576: (8)           arguments, and this function always passes sub-classes through.)
2577: (4)           See also
2578: (4)           -----
2579: (4)           numpy.copy : Similar function with different default behavior
2580: (4)           numpy.copyto
2581: (4)           Notes
2582: (4)           -----
2583: (4)           This function is the preferred method for creating an array copy. The
2584: (4)           function :func:`numpy.copy` is similar, but it defaults to using order
2585: (4)           'K',
2586: (4)           and will not pass sub-classes through by default.
2587: (4)           Examples
2588: (4)           >>> x = np.array([[1,2,3],[4,5,6]], order='F')
2589: (4)           >>> y = x.copy()
2590: (4)           >>> x.fill(0)
2591: (4)           >>> x
2592: (4)           array([[0, 0, 0],
2593: (11)             [0, 0, 0]])
2594: (4)           >>> y
2595: (4)           array([[1, 2, 3],
2596: (11)             [4, 5, 6]])
2597: (4)           >>> y.flags['C_CONTIGUOUS']
2598: (4)           True
2599: (4)           """
2600: (0)           add_newdoc('numpy.core.multiarray', 'ndarray', ('cumprod',
2601: (4)           """
2602: (4)           a.cumprod(axis=None, dtype=None, out=None)
2603: (4)           Return the cumulative product of the elements along the given axis.
2604: (4)           Refer to `numpy.cumprod` for full documentation.
2605: (4)           See Also
2606: (4)           -----
2607: (4)           numpy.cumprod : equivalent function
2608: (4)           """
2609: (0)           add_newdoc('numpy.core.multiarray', 'ndarray', ('cumsum',
2610: (4)           """
2611: (4)           a.cumsum(axis=None, dtype=None, out=None)
2612: (4)           Return the cumulative sum of the elements along the given axis.
2613: (4)           Refer to `numpy.cumsum` for full documentation.
2614: (4)           See Also
2615: (4)           -----
2616: (4)           numpy.cumsum : equivalent function
2617: (4)           """
2618: (0)           add_newdoc('numpy.core.multiarray', 'ndarray', ('diagonal',
2619: (4)           """
2620: (4)           a.diagonal(offset=0, axis1=0, axis2=1)
2621: (4)           Return specified diagonals. In NumPy 1.9 the returned array is a
2622: (4)           read-only view instead of a copy as in previous NumPy versions. In
2623: (4)           a future version the read-only restriction will be removed.
2624: (4)           Refer to :func:`numpy.diagonal` for full documentation.

```

```

2625: (4)           See Also
2626: (4)           -----
2627: (4)           numpy.diagonal : equivalent function
2628: (4)
2629: (0)           """
2630: (0)           add_newdoc('numpy.core.multiarray', 'ndarray', ('dot'))
2631: (4)           add_newdoc('numpy.core.multiarray', 'ndarray', ('dump',
2632: (4)             """a.dump(file)
2633: (4)             Dump a pickle of the array to the specified file.
2634: (4)             The array can be read back with pickle.load or numpy.load.
2635: (4)             Parameters
2636: (4)               -----
2637: (8)                 file : str or Path
2638: (8)                   A string naming the dump file.
2639: (12)                  .. versionchanged:: 1.17.0
2640: (4)                     `pathlib.Path` objects are now accepted.
2641: (0)           """
2642: (4)
2643: (4)           a.dumps()
2644: (4)           Returns the pickle of the array as a string.
2645: (4)           pickle.loads will convert the string back to an array.
2646: (4)           Parameters
2647: (4)             -----
2648: (4)               None
2649: (4)
2650: (0)           """
2651: (4)
2652: (4)           add_newdoc('numpy.core.multiarray', 'ndarray', ('fill',
2653: (4)             """
2654: (4)               a.fill(value)
2655: (4)               Fill the array with a scalar value.
2656: (4)               Parameters
2657: (4)                 -----
2658: (4)                   value : scalar
2659: (4)                     All elements of `a` will be assigned this value.
2660: (4)           Examples
2661: (4)             -----
2662: (4)               >>> a = np.array([1, 2])
2663: (4)               >>> a.fill(0)
2664: (4)               >>> a
2665: (4)               array([0, 0])
2666: (4)               >>> a = np.empty(2)
2667: (4)               >>> a.fill(1)
2668: (4)               >>> a
2669: (4)               array([1., 1.])
2670: (4)               Fill expects a scalar value and always behaves the same as assigning
2671: (4)               to a single array element. The following is a rare example where this
2672: (4)               distinction is important:
2673: (4)               >>> a = np.array([None, None], dtype=object)
2674: (4)               >>> a[0] = np.array(3)
2675: (4)               >>> a
2676: (4)               array([array(3), None], dtype=object)
2677: (4)               >>> a.fill(np.array(3))
2678: (4)               >>> a
2679: (4)               array([array(3), array(3)], dtype=object)
2680: (4)               Where other forms of assignments will unpack the array being assigned:
2681: (4)               >>> a[...] = np.array(3)
2682: (4)
2683: (0)           """
2684: (4)
2685: (4)           add_newdoc('numpy.core.multiarray', 'ndarray', ('flatten',
2686: (4)             """
2687: (4)               a.flatten(order='C')
2688: (4)               Return a copy of the array collapsed into one dimension.
2689: (4)               Parameters
2690: (8)                 -----
2691: (8)                   order : {'C', 'F', 'A', 'K'}, optional
2692: (8)                     'C' means to flatten in row-major (C-style) order.
2693: (8)                     'F' means to flatten in column-major (Fortran-
2694: (8)                     style) order. 'A' means to flatten in column-major
2695: (8)                     order if `a` is Fortran *contiguous* in memory,

```

```

2694: (8)           row-major order otherwise. 'K' means to flatten
2695: (8)           `a` in the order the elements occur in memory.
2696: (8)           The default is 'C'.
2697: (4)           Returns
2698: (4)           -----
2699: (4)           y : ndarray
2700: (8)           A copy of the input array, flattened to one dimension.
2701: (4)           See Also
2702: (4)           -----
2703: (4)           ravel : Return a flattened array.
2704: (4)           flat : A 1-D flat iterator over the array.
2705: (4)           Examples
2706: (4)           -----
2707: (4)           >>> a = np.array([[1,2], [3,4]])
2708: (4)           >>> a.flatten()
2709: (4)           array([1, 2, 3, 4])
2710: (4)           >>> a.flatten('F')
2711: (4)           array([1, 3, 2, 4])
2712: (4)           "''")
2713: (0)           add_newdoc('numpy.core.multiarray', 'ndarray', ('getfield',
2714: (4)           """"
2715: (4)           a.getfield(dtype, offset=0)
2716: (4)           Returns a field of the given array as a certain type.
2717: (4)           A field is a view of the array data with a given data-type. The values in
2718: (4)           the view are determined by the given type and the offset into the current
2719: (4)           array in bytes. The offset needs to be such that the view dtype fits in
the
2720: (4)           array dtype; for example an array of dtype complex128 has 16-byte
elements.
2721: (4)           If taking a view with a 32-bit integer (4 bytes), the offset needs to be
2722: (4)           between 0 and 12 bytes.
2723: (4)           Parameters
2724: (4)           -----
2725: (4)           dtype : str or dtype
2726: (8)           The data type of the view. The dtype size of the view can not be
larger
2727: (8)           than that of the array itself.
2728: (4)           offset : int
2729: (8)           Number of bytes to skip before beginning the element view.
2730: (4)           Examples
2731: (4)           -----
2732: (4)           >>> x = np.diag([1.+1.j]*2)
2733: (4)           >>> x[1, 1] = 2 + 4.j
2734: (4)           >>> x
2735: (4)           array([[1.+1.j,  0.+0.j],
2736: (11)           [0.+0.j,  2.+4.j]])
2737: (4)           >>> x.getfield(np.float64)
2738: (4)           array([[1.,  0.],
2739: (11)           [0.,  2.]])
2740: (4)           By choosing an offset of 8 bytes we can select the complex part of the
2741: (4)           array for our view:
2742: (4)           >>> x.getfield(np.float64, offset=8)
2743: (4)           array([[1.,  0.],
2744: (11)           [0.,  4.]])
2745: (4)           """")
2746: (0)           add_newdoc('numpy.core.multiarray', 'ndarray', ('item',
2747: (4)           """"
2748: (4)           a.item(*args)
2749: (4)           Copy an element of an array to a standard Python scalar and return it.
2750: (4)           Parameters
2751: (4)           -----
2752: (4)           \\\*args : Arguments (variable number and type)
2753: (8)           * none: in this case, the method only works for arrays
2754: (10)           with one element (`a.size == 1`), which element is
2755: (10)           copied into a standard Python scalar object and returned.
2756: (8)           * int_type: this argument is interpreted as a flat index into
2757: (10)           the array, specifying which element to copy and return.
2758: (8)           * tuple of int_types: functions as does a single int_type argument,
2759: (10)           except that the argument is interpreted as an nd-index into the

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

2760: (10)           array.
2761: (4)           Returns
2762: (4)
2763: (4)           z : Standard Python scalar object
2764: (8)           A copy of the specified element of the array as a suitable
2765: (8)           Python scalar
2766: (4)           Notes
2767: (4)
2768: (4)           When the data type of `a` is longdouble or clongdouble, item() returns
2769: (4)           a scalar array object because there is no available Python scalar that
2770: (4)           would not lose information. Void arrays return a buffer object for item(),
2771: (4)           unless fields are defined, in which case a tuple is returned.
2772: (4)           `item` is very similar to a[args], except, instead of an array scalar,
2773: (4)           a standard Python scalar is returned. This can be useful for speeding up
2774: (4)           access to elements of the array and doing arithmetic on elements of the
2775: (4)           array using Python's optimized math.
2776: (4)           Examples
2777: (4)
2778: (4)           >>> np.random.seed(123)
2779: (4)           >>> x = np.random.randint(9, size=(3, 3))
2780: (4)           >>> x
2781: (4)           array([[2, 2, 6],
2782: (11)             [1, 3, 6],
2783: (11)             [1, 0, 1]])
2784: (4)           >>> x.item(3)
2785: (4)           1
2786: (4)           >>> x.item(7)
2787: (4)           0
2788: (4)           >>> x.item((0, 1))
2789: (4)           2
2790: (4)           >>> x.item((2, 2))
2791: (4)           1
2792: (4)           ""))
2793: (0)           add_newdoc('numpy.core.multiarray', 'ndarray', ('itemset',
2794: (4)           """
2795: (4)           a.itemset(*args)
2796: (4)           Insert scalar into an array (scalar is cast to array's dtype, if possible)
2797: (4)           There must be at least 1 argument, and define the last argument
2798: (4)           as *item*. Then, ``a.itemset(*args)`` is equivalent to but faster
2799: (4)           than ``a[args] = item``. The item should be a scalar value and `args`
2800: (4)           must select a single item in the array `a`.
2801: (4)           Parameters
2802: (4)
2803: (4)           \\*args : Arguments
2804: (8)           If one argument: a scalar, only used in case `a` is of size 1.
2805: (8)           If two arguments: the last argument is the value to be set
2806: (8)           and must be a scalar, the first argument specifies a single array
2807: (8)           element location. It is either an int or a tuple.
2808: (4)           Notes
2809: (4)
2810: (4)           Compared to indexing syntax, `itemset` provides some speed increase
2811: (4)           for placing a scalar into a particular location in an `ndarray`,
2812: (4)           if you must do this. However, generally this is discouraged:
2813: (4)           among other problems, it complicates the appearance of the code.
2814: (4)           Also, when using `itemset` (and `item`) inside a loop, be sure
2815: (4)           to assign the methods to a local variable to avoid the attribute
2816: (4)           look-up at each loop iteration.
2817: (4)           Examples
2818: (4)
2819: (4)           >>> np.random.seed(123)
2820: (4)           >>> x = np.random.randint(9, size=(3, 3))
2821: (4)           >>> x
2822: (4)           array([[2, 2, 6],
2823: (11)             [1, 3, 6],
2824: (11)             [1, 0, 1]])
2825: (4)           >>> x.itemset(4, 0)
2826: (4)           >>> x.itemset((2, 2), 9)
2827: (4)           >>> x
2828: (4)           array([[2, 2, 6],

2968: (4)        Parameters  
2969: (4)  
2970: (4)        -----  
2971: (4)        new\_shape : tuple of ints, or `n` ints  
2972: (4)        Shape of resized array.  
2973: (4)        refcheck : bool, optional  
2974: (4)        If False, reference count will not be checked. Default is True.  
2975: (4)        Returns

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

2966: (4)
2967: (4)
2968: (4)
2969: (4)
2970: (4)
2971: (8)      -----
2972: (8)      None
2973: (8)      Raises
2974: (8)      -----
2975: (8)      ValueError
2976: (8)      If `a` does not own its own data or references or views to it exist,
2977: (8)      and the data memory must be changed.
2978: (8)      PyPy only: will always raise if the data memory must be changed, since
2979: (8)      there is no reliable way to determine if references or views to it
2980: (8)      exist.
2981: (8)      -----
2982: (8)      SystemError
2983: (8)      If the `order` keyword argument is specified. This behaviour is a
2984: (8)      bug in NumPy.
2985: (8)      See Also
2986: (8)      -----
2987: (8)      resize : Return a new array with the specified shape.
2988: (8)      Notes
2989: (8)      -----
2990: (8)      This reallocates space for the data area if necessary.
2991: (8)      Only contiguous arrays (data elements consecutive in memory) can be
2992: (8)      resized.
2993: (8)      The purpose of the reference count check is to make sure you
2994: (8)      do not use this array as a buffer for another Python object and then
2995: (8)      reallocate the memory. However, reference counts can increase in
2996: (8)      other ways so if you are sure that you have not shared the memory
2997: (8)      for this array with another Python object, then you may safely set
2998: (8)      `refcheck` to False.
2999: (8)      Examples
3000: (8)      -----
3001: (11)     Shrinking an array: array is flattened (in the order that the data are
3002: (4)      stored in memory), resized, and reshaped:
3003: (4)      >>> a = np.array([[0, 1], [2, 3]], order='C')
3004: (4)      >>> a.resize((2, 1))
3005: (4)      >>> a
3006: (11)     array([[0],
3007: (4)      [1]])
3008: (4)      >>> a = np.array([[0, 1], [2, 3]], order='F')
3009: (4)      >>> a.resize((2, 1))
3010: (4)      >>> a
3011: (4)      array([[0],
3012: (11)     [1]])
3013: (4)      Enlarging an array: as above, but missing entries are filled with zeros:
3014: (4)      >>> b = np.array([[0, 1], [2, 3]])
3015: (4)      >>> b.resize(2, 3) # new_shape parameter doesn't have to be a tuple
3016: (4)      >>> b
3017: (4)      array([[0, 1, 2],
3018: (4)      [3, 0, 0]])
3019: (4)      Referencing an array prevents resizing...
3020: (4)      >>> c = a
3021: (4)      >>> a.resize((1, 1))
3022: (4)      Traceback (most recent call last):
3023: (4)      ...
3024: (4)      ValueError: cannot resize an array that references or is referenced ...
3025: (4)      Unless `refcheck` is False:
3026: (0)      >>> a.resize((1, 1), refcheck=False)
3027: (4)      >>> a
3028: (4)      array([[0]])

add_newdoc('numpy.core.multiarray', 'ndarray', ('setfield',
        """
            a.setfield(val, dtype, offset=0)
            Put a value into a specified place in a field defined by a data-type.
            Place `val` into `a`'s field defined by `dtype` and beginning `offset`
            bytes into the field.
            Parameters
            -----
            val : object
                Value to be placed in field.
            dtype : dtype object
                Data-type of the field in which to place `val`.
            offset : int, optional
                The number of bytes into the field at which to place `val`.
            Returns
            -----
            None

        """))
add_newdoc('numpy.core.multiarray', 'ndarray', ('setflags',
        """
            a.setflags(write=None, align=None, uic=None)
            Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY,
            respectively.
            These Boolean-valued flags affect how numpy interprets the memory
            area used by `a` (see Notes below). The ALIGNED flag can only
            be set to True if the data is actually aligned according to the type.
            The WRITEBACKIFCOPY and flag can never be set
            to True. The flag WRITEABLE can only be set to True if the array owns its
            own memory, or the ultimate owner of the memory exposes a writeable buffer
            interface, or is a string. (The exception for string is made so that
            unpickling can be done without copying memory.)
            Parameters
            -----
            write : bool, optional
                Describes whether or not `a` can be written to.
        """))

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

3103: (4) align : bool, optional
3104: (8)     Describes whether or not `a` is aligned properly for its type.
3105: (4) uic : bool, optional
3106: (8)     Describes whether or not `a` is a copy of another "base" array.
3107: (4) Notes
3108: (4) -----
3109: (4) Array flags provide information about how the memory area used
3110: (4) for the array is to be interpreted. There are 7 Boolean flags
3111: (4) in use, only four of which can be changed by the user:
3112: (4) WRITEBACKIFCOPY, WRITEABLE, and ALIGNED.
3113: (4) WRITEABLE (W) the data area can be written to;
3114: (4) ALIGNED (A) the data and strides are aligned appropriately for the
hardware
3115: (4) (as determined by the compiler);
3116: (4) WRITEBACKIFCOPY (X) this array is a copy of some other array (referenced
3117: (4) by .base). When the C-API function PyArray_ResolveWritebackIfCopy is
3118: (4) called, the base array will be updated with the contents of this array.
3119: (4) All flags can be accessed using the single (upper case) letter as well
3120: (4) as the full name.
3121: (4) Examples
3122: (4) -----
3123: (4) >>> y = np.array([[3, 1, 7],
3124: (4) ...           [2, 0, 0],
3125: (4) ...           [8, 5, 9]])
3126: (4) >>> y
3127: (4) array([[3, 1, 7],
3128: (11) ...           [2, 0, 0],
3129: (11) ...           [8, 5, 9]])
3130: (4) >>> y.flags
3131: (6)     C_CONTIGUOUS : True
3132: (6)     F_CONTIGUOUS : False
3133: (6)     OWNDATA : True
3134: (6)     WRITEABLE : True
3135: (6)     ALIGNED : True
3136: (6)     WRITEBACKIFCOPY : False
3137: (4) >>> y.setflags(write=0, align=0)
3138: (4) >>> y.flags
3139: (6)     C_CONTIGUOUS : True
3140: (6)     F_CONTIGUOUS : False
3141: (6)     OWNDATA : True
3142: (6)     WRITEABLE : False
3143: (6)     ALIGNED : False
3144: (6)     WRITEBACKIFCOPY : False
3145: (4) >>> y.setflags(uic=1)
3146: (4) Traceback (most recent call last):
3147: (6)   File "<stdin>", line 1, in <module>
3148: (4) ValueError: cannot set WRITEBACKIFCOPY flag to True
3149: (4) """
3150: (0) add_newdoc('numpy.core.multiarray', 'ndarray', ('sort',
3151: (4) """
3152: (4)     a.sort(axis=-1, kind=None, order=None)
3153: (4)     Sort an array in-place. Refer to `numpy.sort` for full documentation.
3154: (4) Parameters
3155: (4) -----
3156: (4)     axis : int, optional
3157: (8)         Axis along which to sort. Default is -1, which means sort along the
3158: (8)         last axis.
3159: (4)     kind : {'quicksort', 'mergesort', 'heapsort', 'stable'}, optional
3160: (8)         Sorting algorithm. The default is 'quicksort'. Note that both 'stable'
3161: (8)         and 'mergesort' use timsort under the covers and, in general, the
3162: (8)         actual implementation will vary with datatype. The 'mergesort' option
3163: (8)         is retained for backwards compatibility.
3164: (8)         .. versionchanged:: 1.15.0
3165: (11)             The 'stable' option was added.
3166: (4)     order : str or list of str, optional
3167: (8)         When `a` is an array with fields defined, this argument specifies
3168: (8)         which fields to compare first, second, etc. A single field can
3169: (8)         be specified as a string, and not all fields need be specified,
3170: (8)         but unspecified fields will still be used, in the order in which

```

```

3171: (8)           they come up in the dtype, to break ties.
3172: (4)           See Also

3181: (4)           -----
3182: (4)           See `numpy.sort` for notes on the different sorting algorithms.
3183: (4)           Examples
3184: (4)           -----
3185: (4)           >>> a = np.array([[1,4], [3,1]])
3186: (4)           >>> a.sort(axis=1)
3187: (4)           >>> a
3188: (11)          array([[1, 4],
3189: (4)           [1, 3]])
3190: (4)           >>> a.sort(axis=0)
3191: (4)           >>> a
3192: (11)          array([[1, 3],
3193: (4)           [1, 4]])
3194: (4)           Use the `order` keyword to specify a field to use when sorting a
3195: (4)           structured array:
3196: (4)           >>> a = np.array([('a', 2), ('c', 1)], dtype=[('x', 'S1'), ('y', int)])
3197: (4)           >>> a.sort(order='y')
3198: (4)           >>> a
3199: (10)          array([(b'c', 1), (b'a', 2)],
3200: (4)           dtype=[('x', 'S1'), ('y', '<i8')])
3201: (0)           """
3202: (4)           add_newdoc('numpy.core.multiarray', 'ndarray', ('partition',
3203: (4)           """
3204: (4)           a.partition(kth, axis=-1, kind='introselect', order=None)
3205: (4)           Rearranges the elements in the array in such a way that the value of the
3206: (4)           element in kth position is in the position it would be in a sorted array.
3207: (4)           All elements smaller than the kth element are moved before this element
and
3208: (4)           all equal or greater are moved behind it. The ordering of the elements in
3209: (4)           the two partitions is undefined.
3210: (4)           .. versionadded:: 1.8.0
3211: (4)           Parameters
3212: (4)           -----
3213: (8)           kth : int or sequence of ints
3214: (8)           Element index to partition by. The kth element value will be in its
3215: (8)           final sorted position and all smaller elements will be moved before it
3216: (8)           and all equal or greater elements behind it.
3217: (8)           The order of all elements in the partitions is undefined.
3218: (8)           If provided with a sequence of kth it will partition all elements
3219: (8)           indexed by kth of them into their sorted position at once.
3220: (12)          .. deprecated:: 1.22.0
3221: (4)           Passing booleans as index is deprecated.
3222: (8)           axis : int, optional
3223: (8)           Axis along which to sort. Default is -1, which means sort along the
3224: (4)           last axis.
3225: (8)           kind : {'introselect'}, optional
3226: (4)           Selection algorithm. Default is 'introselect'.
3227: (8)           order : str or list of str, optional
3228: (8)           When `a` is an array with fields defined, this argument specifies
3229: (8)           which fields to compare first, second, etc. A single field can
3230: (8)           be specified as a string, and not all fields need to be specified,
3231: (8)           but unspecified fields will still be used, in the order in which

3339: (4)           -----
3340: (4)           none
3341: (4)           Returns
3342: (4)           -----
3343: (4)           y : object, or list of object, or list of list of object, or ...
3344: (8)           The possibly nested list of array elements.
3345: (4)           Notes
3346: (4)           -----
3347: (4)           The array may be recreated via ``a = np.array(a.tolist())``, although this
3348: (4)           may sometimes lose precision.
3349: (4)           Examples
3350: (4)           -----
3351: (4)           For a 1D array, ``a.tolist()`` is almost the same as ``list(a)``,
3352: (4)           except that ``tolist`` changes numpy scalars to Python scalars:
3353: (4)           >>> a = np.uint32([1, 2])
3354: (4)           >>> a_list = list(a)
3355: (4)           >>> a_list
3356: (4)           [1, 2]
3357: (4)           >>> type(a_list[0])
3358: (4)           <class 'numpy.uint32'>
3359: (4)           >>> a.tolist = a.tolist()
3360: (4)           >>> a.tolist
3361: (4)           [1, 2]
3362: (4)           >>> type(a.tolist[0])
3363: (4)           <class 'int'>
3364: (4)           Additionally, for a 2D array, ``tolist`` applies recursively:
3365: (4)           >>> a = np.array([[1, 2], [3, 4]])
3366: (4)           >>> list(a)
3367: (4)           [array([1, 2]), array([3, 4])]
3368: (4)
3369: (4)
3370: (4)
3371: (4)
3372: (4)

```

```

3373: (4)           Traceback (most recent call last):
3374: (6)             ...
3375: (4)             TypeError: iteration over a 0-d array
3376: (4)             >>> a.tolist()
3377: (4)             1
3378: (4)             "''")
3379: (0)             add_newdoc('numpy.core.multiarray', 'ndarray', ('tobytes', """
3380: (4)               a.tobytes(order='C')
3381: (4)               Construct Python bytes containing the raw data bytes in the array.
3382: (4)               Constructs Python bytes showing a copy of the raw contents of
3383: (4)               data memory. The bytes object is produced in C-order by default.
3384: (4)               This behavior is controlled by the ``order`` parameter.
3385: (4)               .. versionadded:: 1.9.0
3386: (4)             Parameters
3387: (4)             -----
3388: (4)             order : {'C', 'F', 'A'}, optional
3389: (8)               Controls the memory layout of the bytes object. 'C' means C-order,
3390: (8)               'F' means F-order, 'A' (short for *Any*) means 'F' if `a` is
3391: (8)               Fortran contiguous, 'C' otherwise. Default is 'C'.
3392: (4)             Returns
3393: (4)             -----
3394: (4)             s : bytes
3395: (8)               Python bytes exhibiting a copy of `a`'s raw data.
3396: (4)             See also
3397: (4)             -----
3398: (4)             frombuffer
3399: (8)               Inverse of this operation, construct a 1-dimensional array from Python
3400: (8)               bytes.
3401: (4)             Examples
3402: (4)             -----
3403: (4)             >>> x = np.array([[0, 1], [2, 3]], dtype='<u2')
3404: (4)             >>> x.tobytes()
3405: (4)             b'\x00\x00\x01\x00\x02\x00\x03\x00'
3406: (4)             >>> x.tobytes('C') == x.tobytes()
3407: (4)             True
3408: (4)             >>> x.tobytes('F')
3409: (4)             b'\x00\x00\x02\x00\x01\x00\x03\x00'
3410: (4)             "''")
3411: (0)             add_newdoc('numpy.core.multiarray', 'ndarray', ('tostring', r"""
3412: (4)               a.tostring(order='C')
3413: (4)               A compatibility alias for `tobytes`, with exactly the same behavior.
3414: (4)               Despite its name, it returns `bytes` not `str`\ s.
3415: (4)               .. deprecated:: 1.19.0
3416: (4)               "''"))

3452: (4)                                array([[1, 2],
3453: (11)                               [3, 4]])
3454: (4)                                >>> a.transpose()
3455: (4)                                array([[1, 3],
3456: (11)                               [2, 4]])
3457: (4)                                >>> a.transpose((1, 0))
3458: (4)                                array([[1, 3],
3459: (11)                               [2, 4]])
3460: (4)                                >>> a.transpose(1, 0)
3461: (4)                                array([[1, 3],
3462: (11)                               [2, 4]])
3463: (4)                                >>> a = np.array([1, 2, 3, 4])
3464: (4)                                >>> a
3465: (4)                                array([1, 2, 3, 4])
3466: (4)                                >>> a.transpose()
3467: (4)                                array([1, 2, 3, 4])
3468: (4)                                "''")
3469: (0)                                add_newdoc('numpy.core.multiarray', 'ndarray', ('var',
3470: (4)                                "''"
3471: (4)                                a.var(axis=None, dtype=None, out=None, ddof=0, keepdims=False, *,
where=True)
3472: (4)                                Returns the variance of the array elements, along given axis.
3473: (4)                                Refer to `numpy.var` for full documentation.
3474: (4)                                See Also
3475: (4)
3476: (4)                                numpy.var : equivalent function
3477: (4)                                "'''")
3478: (0)                                add_newdoc('numpy.core.multiarray', 'ndarray', ('view',
3479: (4)                                "''"
3480: (4)                                a.view([dtype][, type]))
3481: (4)                                New view of array with the same data.
3482: (4)                                .. note::
3483: (8)                                Passing None for ``dtype`` is different from omitting the parameter,
3484: (8)                                since the former invokes ``dtype(None)`` which is an alias for
3485: (8)                                ``dtype('float_')``.
3486: (4)                                Parameters
3487: (4)
3488: (4)                                dtype : data-type or ndarray sub-class, optional
3489: (8)                                Data-type descriptor of the returned view, e.g., float32 or int16.
3490: (8)                                Omitting it results in the view having the same data-type as `a`.
3491: (8)                                This argument can also be specified as an ndarray sub-class, which
3492: (8)                                then specifies the type of the returned object (this is equivalent to
3493: (8)                                setting the ``type`` parameter).
3494: (4)                                type : Python type, optional
3495: (8)                                Type of the returned view, e.g., ndarray or matrix. Again, omission
3496: (8)                                of the parameter results in type preservation.
3497: (4)                                Notes
3498: (4)
3499: (4)                                ``a.view()`` is used two different ways:
3500: (4)                                ``a.view(some_dtype)`` or ``a.view(dtype=some_dtype)`` constructs a view
3501: (4)                                of the array's memory with a different data-type. This can cause a
3502: (4)                                reinterpretation of the bytes of memory.
3503: (4)                                ``a.view(ndarray_subclass)`` or ``a.view(type=ndarray_subclass)`` just
3504: (4)                                returns an instance of `ndarray_subclass` that looks at the same array
3505: (4)                                (same shape, dtype, etc.) This does not cause a reinterpretation of the
3506: (4)                                memory.
3507: (4)                                For ``a.view(some_dtype)``, if ``some_dtype`` has a different number of
3508: (4)                                bytes per entry than the previous dtype (for example, converting a regular
3509: (4)                                array to a structured array), then the last axis of ``a`` must be

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

3510: (4) contiguous. This axis will be resized in the result.
3511: (4) .. versionchanged:: 1.23.0
3512: (7) Only the last axis needs to be contiguous. Previously, the entire array
3513: (7) had to be C-contiguous.
3514: (4) Examples
3515: (4) -----
3516: (4) >>> x = np.array([(1, 2)], dtype=[('a', np.int8), ('b', np.int8)])
3517: (4) Viewing array data using a different type and dtype:
3518: (4) >>> y = x.view(dtype=np.int16, type=np.matrix)
3519: (4) >>> y
3520: (4) matrix([[513]], dtype=int16)
3521: (4) >>> print(type(y))
3522: (4) <class 'numpy.matrix'>
3523: (4) Creating a view on a structured array so it can be used in calculations
3524: (4) >>> x = np.array([(1, 2),(3,4)], dtype=[('a', np.int8), ('b', np.int8)])
3525: (4) >>> xv = x.view(dtype=np.int8).reshape(-1,2)
3526: (4) >>> xv
3527: (4) array([[1, 2],
3528: (11)     [3, 4]], dtype=int8)
3529: (4) >>> xv.mean(0)
3530: (4) array([2., 3.])
3531: (4) Making changes to the view changes the underlying array
3532: (4) >>> xv[0,1] = 20
3533: (4) >>> x
3534: (4) array([(1, 20), (3, 4)], dtype=[('a', 'i1'), ('b', 'i1')])
3535: (4) Using a view to convert an array to a recarray:
3536: (4) >>> z = x.view(np.recarray)
3537: (4) >>> z.a
3538: (4) array([1, 3], dtype=int8)
3539: (4) Views share data:
3540: (4) >>> x[0] = (9, 10)
3541: (4) >>> z[0]
3542: (4) (9, 10)
3543: (4) Views that change the dtype size (bytes per entry) should normally be
3544: (4) avoided on arrays defined by slices, transposes, fortran-ordering, etc.:
3545: (4) >>> x = np.array([[1, 2, 3], [4, 5, 6]], dtype=np.int16)
3546: (4) >>> y = x[:, ::2]
3547: (4) >>> y
3548: (4) array([[1, 3],
3549: (11)     [4, 6]], dtype=int16)
3550: (4) >>> y.view(dtype=[('width', np.int16), ('length', np.int16)])
3551: (4) Traceback (most recent call last):
3552: (8) ...
3553: (4) ValueError: To change to a dtype of a different size, the last axis must
be contiguous
3554: (4) >>> z = y.copy()
3555: (4) >>> z.view(dtype=[('width', np.int16), ('length', np.int16)])
3556: (4) array([[[(1, 3)],
3557: (11)     [(4, 6)]], dtype=[('width', '<i2'), ('length', '<i2')])
3558: (4) However, views that change dtype are totally fine for arrays with a
3559: (4) contiguous last axis, even if the rest of the axes are not C-contiguous:
3560: (4) >>> x = np.arange(2 * 3 * 4, dtype=np.int8).reshape(2, 3, 4)
3561: (4) >>> x.transpose(1, 0, 2).view(np.int16)
3562: (4) array([[[ 256,  770],
3563: (12)     [3340, 3854]],
3564: (4) <BLANKLINE>
3565: (11)     [[1284, 1798],
3566: (12)     [4368, 4882]],
3567: (4) <BLANKLINE>
3568: (11)     [[2312, 2826],
3569: (12)     [5396, 5910]]], dtype=int16)
3570: (4)     ""))
3571: (0) add_newdoc('numpy.core.umath', 'frompyfunc',
3572: (4)     """
3573: (4)         frompyfunc(func, /, nin, nout, *[, identity])
3574: (4)         Takes an arbitrary Python function and returns a NumPy ufunc.
3575: (4)         Can be used, for example, to add broadcasting to a built-in Python
3576: (4)         function (see Examples section).

-----  

func : Python function object  

An arbitrary Python function.  

nin : int  

The number of input arguments.  

nout : int  

The number of objects returned by `func`.  

identity : object, optional  

The value to use for the `~numpy.ufunc.identity` attribute of the  

object. If specified, this is equivalent to setting the underlying  

C ``identity`` field to ``PyUFunc_IdentityValue``.  

If omitted, the identity is set to ``PyUFunc_None``. Note that this is  

_not_ equivalent to setting the identity to ``None``, which implies  

operation is reorderable.  

Returns  

-----  

out : ufunc  

Returns a NumPy universal function (``ufunc``) object.  

See Also  

-----  

vectorize : Evaluates pyfunc over input arrays using broadcasting rules of  

numpy.  

Notes  

-----  

The returned ufunc always returns PyObject arrays.  

Examples  

-----  

Use frompyfunc to add broadcasting to the Python function ``oct``:  

>>> oct_array = np.frompyfunc(oct, 1, 1)  

>>> oct_array(np.array((10, 30, 100)))  

array(['0o12', '0o36', '0o144'], dtype=object)  

>>> np.array((oct(10), oct(30), oct(100))) # for comparison  

array(['0o12', '0o36', '0o144'], dtype='<U5')  

""")  

add_newdoc('numpy.core.umath', 'geterrobj',  

        """  

geterrobj()  

Return the current object that defines floating-point error handling.  

The error object contains all information that defines the error handling  

behavior in NumPy. `geterrobj` is used internally by the other  

functions that get and set error handling behavior (`geterr`, `seterr`,  

`geterrcall`, `seterrcall`).  

Returns  

-----  

errobj : list  

The error object, a list containing three elements:  

[internal numpy buffer size, error mask, error callback function].  

The error mask is a single integer that holds the treatment  

on all four floating point errors. The information for each error type  

is contained in three bits of the integer. If we print it in base 8,  

we  

can see what treatment is set for "invalid", "under", "over", and  

"divide" (in that order). The printed string can be interpreted with  

* 0 : 'ignore'  

* 1 : 'warn'  

* 2 : 'raise'  

* 3 : 'call'  

* 4 : 'print'  

* 5 : 'log'  

See Also  

-----  

seterrobj, seterr, geterr, seterrcall, geterrcall  

getbufsize, setbufsize  

Notes  

-----  

For complete documentation of the types of floating-point exceptions and

3712: (4)             """
3713: (4)                 add_docstring(obj, docstring)
3714: (4)                 Add a docstring to a built-in obj if possible.
3715: (4)                 If the obj already has a docstring raise a RuntimeError
3716: (4)                 If this routine does not know how to add a docstring to the object
3717: (4)                 raise a TypeError
3718: (4)             """
3719: (0)             add_newdoc('numpy.core.umath', '_add_newdoc_ufunc',
3720: (4)             """
3721: (4)                 add_ufunc_docstring(ufunc, new_docstring)
3722: (4)                 Replace the docstring for a ufunc with new_docstring.
3723: (4)                 This method will only work if the current docstring for
3724: (4)                 the ufunc is NULL. (At the C level, i.e. when ufunc->doc is NULL.)
3725: (4)                 Parameters
3726: (4)                 -----
3727: (4)                 ufunc : numpy.ufunc
3728: (8)                   A ufunc whose current doc is NULL.
3729: (4)                 new_docstring : string
3730: (8)                   The new docstring for the ufunc.
3731: (4)                 Notes
3732: (4)                 -----
3733: (4)                   This method allocates memory for new_docstring on
3734: (4)                   the heap. Technically this creates a memory leak, since this
3735: (4)                   memory will not be reclaimed until the end of the program
3736: (4)                   even if the ufunc itself is removed. However this will only
3737: (4)                   be a problem if the user is repeatedly creating ufuncs with
3738: (4)                   no documentation, adding documentation via add_newdoc_ufunc,
3739: (4)                   and then throwing away the ufunc.
3740: (4)             """

3768: (4)                 allocating the array data. Returns the previously set value.
3769: (4)                 See `global_state` for more information.
3770: (4)             """
3771: (0)             add_newdoc('numpy.core._multiarray_tests', 'format_float_OSpprintf_g',
3772: (4)             """
3773: (4)                 format_float_OSpprintf_g(val, precision)

```

```

3774: (4)          Print a floating point scalar using the system's printf function,
3775: (4)          equivalent to:
3776: (8)            printf("%.*g", precision, val);
3777: (4)          for half/float/double, or replacing 'g' by 'Lg' for longdouble. This
3778: (4)          method is designed to help cross-validate the format_float_* methods.
3779: (4)          Parameters
3780: (4)            -----
3781: (4)              val : python float or numpy floating scalar
3782: (8)                Value to format.
3783: (4)              precision : non-negative integer, optional
3784: (8)                Precision given to printf.
3785: (4)          Returns
3786: (4)            -----
3787: (4)              rep : string
3788: (8)                The string representation of the floating point value
3789: (4)          See Also
3790: (4)            -----
3791: (4)              format_float_scientific
3792: (4)              format_float_positional
3793: (4)              """")
3794: (0)          add_newdoc('numpy.core', 'ufunc',
3795: (4)            """
3796: (4)          Functions that operate element by element on whole arrays.
3797: (4)          To see the documentation for a specific ufunc, use `info`. For
3798: (4)          example, ``np.info(np.sin)``. Because ufuncs are written in C
3799: (4)          (for speed) and linked into Python with NumPy's ufunc facility,
3800: (4)          Python's help() function finds this page whenever help() is called
3801: (4)          on a ufunc.
3802: (4)          A detailed explanation of ufuncs can be found in the docs for
:ref:`ufuncs`.
3803: (4)          **Calling ufuncs:** ``op(*x[, out], where=True, **kwargs)``
3804: (4)          Apply `op` to the arguments ``*x`` elementwise, broadcasting the arguments.
3805: (4)          The broadcasting rules are:
3806: (4)            * Dimensions of length 1 may be prepended to either array.
3807: (4)            * Arrays may be repeated along dimensions of length 1.
3808: (4)          Parameters
3809: (4)            -----
3810: (4)              *x : array_like
3811: (8)                Input arrays.
3812: (4)              out : ndarray, None, or tuple of ndarray and None, optional
3813: (8)                Alternate array object(s) in which to put the result; if provided, it
3814: (8)                must have a shape that the inputs broadcast to. A tuple of arrays
3815: (8)                (possibly only as a keyword argument) must have length equal to the
3816: (8)                number of outputs; use None for uninitialized outputs to be
3817: (8)                allocated by the ufunc.
3818: (4)              where : array_like, optional
3819: (8)                This condition is broadcast over the input. At locations where the
3820: (8)                condition is True, the `out` array will be set to the ufunc result.
3821: (8)                Elsewhere, the `out` array will retain its original value.
3822: (8)                Note that if an uninitialized `out` array is created via the default
3823: (8)                ``out=None``, locations within it where the condition is False will
3824: (8)                remain uninitialized.
3825: (4)              **kwargs
3826: (8)                For other keyword-only arguments, see the :ref:`ufunc docs
<ufuncs.kwargs>`.
```

3827: (4) Returns

3828: (4) -----

3829: (4) r : ndarray or tuple of ndarray

3830: (8) `r` will have the shape that the arrays in `x` broadcast to; if `out`

is

3831: (8) provided, it will be returned. If not, `r` will be allocated and

3832: (8) may contain uninitialized values. If the function has more than one

3833: (8) output, then the result will be a tuple of arrays.

3834: (4) """")

3835: (0) add\_newdoc('numpy.core', 'ufunc', ('identity',
3836: (4) """
3837: (4) The identity value.
3838: (4) Data attribute containing the identity element for the ufunc, if it has
one.

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

3839: (4) If it does not, the attribute value is None.  
3840: (4) Examples  
3841: (4) -----  
3842: (4) >>> np.add.identity  
3843: (4) 0  
3844: (4) >>> np.multiply.identity  
3845: (4) 1  
3846: (4) >>> np.power.identity  
3847: (4) 1  
3848: (4) >>> print(np.exp.identity)  
3849: (4) None  
3850: (4) """))  
3851: (0) add\_newdoc('numpy.core', 'ufunc', ('nargs',  
3852: (4) """  
3853: (4) The number of arguments.  
3854: (4) Data attribute containing the number of arguments the ufunc takes,  
including  
3855: (4) optional ones.  
3856: (4) Notes  
3857: (4) -----  
3858: (4) Typically this value will be one more than what you might expect because  
all  
3859: (4) ufuncs take the optional "out" argument.  
3860: (4) Examples  
3861: (4) -----  
3862: (4) >>> np.add.nargs  
3863: (4) 3  
3864: (4) >>> np.multiply.nargs  
3865: (4) 3

3953: (0)      add_newdoc('numpy.core', 'ufunc', ('signature',
3954: (4)          """
3955: (4)          Definition of the core elements a generalized ufunc operates on.
3956: (4)          The signature determines how the dimensions of each input/output array
are split into core and loop dimensions:
3957: (4)          1. Each dimension in the signature is matched to a dimension of the
corresponding passed-in array, starting from the end of the shape
tuple.
3958: (4)
3959: (7)          tuple.
3960: (4)          2. Core dimensions assigned to the same label in the signature must have
exactly matching sizes, no broadcasting is performed.
3961: (7)          3. The core dimensions are removed from all inputs and the remaining
dimensions are broadcast together, defining the loop dimensions.
3962: (4)          Notes
3963: (4)          -----
3964: (4)          Generalized ufuncs are used internally in many linalg functions, and in
the testing suite; the examples below are taken from these.
3965: (4)          For ufuncs that operate on scalars, the signature is None, which is

```

```

3969: (4) equivalent to '()' for every argument.
3970: (4) Examples
3971: (4)
3972: (4) -----
3973: (4) >>> np.core.umath_tests.matrix_multiply.signature
3974: (4) '(m,n),(n,p)->(m,p)'
3975: (4) >>> np.linalg._umath_linalg.det.signature
3976: (4) '(m,m)->()'
3977: (4) >>> np.add.signature is None
3978: (4) True # equivalent to '(),()->()'
3979: (4) """
3980: (4) add_newdoc('numpy.core', 'ufunc', ('reduce',
3981: (4) """"
3982: (4) reduce(array, axis=0, dtype=None, out=None, keepdims=False, initial=<no
3983: (4) value>, where=True)
3984: (4) =
3985: (4) the result of iterating `j` over :math:`range(N_i)`, cumulatively applying
3986: (4) ufunc to each :math:`array[k_0, \dots, k_{i-1}, j, k_{i+1}, \dots, k_{M-1}]` .
3987: (4) For a one-dimensional array, reduce produces results equivalent to:
3988: (4) :::
3989: (5) r = op.identity # op = ufunc
3990: (5) for i in range(len(A)):
3991: (7)     r = op(r, A[i])
3992: (5) return r
3993: (4) For example, add.reduce() is equivalent to sum().
3994: (4) Parameters
3995: (4) -----
3996: (4) array : array_like
3997: (8)     The array to act on.
3998: (4) axis : None or int or tuple of ints, optional
3999: (8)     Axis or axes along which a reduction is performed.
4000: (8)     The default (`axis` = 0) is perform a reduction over the first
4001: (8)     dimension of the input array. `axis` may be negative, in
4002: (8)     which case it counts from the last to the first axis.
4003: (8) .. versionadded:: 1.7.0
4004: (8) If this is None, a reduction is performed over all the axes.
4005: (8) If this is a tuple of ints, a reduction is performed on multiple
4006: (8) axes, instead of a single axis or all the axes as before.
4007: (8) For operations which are either not commutative or not associative,
4008: (8) doing a reduction over multiple axes is not well-defined. The
4009: (8) ufuncs do not currently raise an exception in this case, but will
4010: (8) likely do so in the future.
4011: (4) dtype : data-type code, optional
4012: (8)     The type used to represent the intermediate results. Defaults
4013: (8)     to the data-type of the output array if this is provided, or
4014: (8)     the data-type of the input array if no output array is provided.
4015: (4) out : ndarray, None, or tuple of ndarray and None, optional
4016: (8)     A location into which the result is stored. If not provided or None,
4017: (8)     a freshly-allocated array is returned. For consistency with
4018: (8)     ``ufunc.__call__``, if given as a keyword, this may be wrapped in a
4019: (8)     1-element tuple.
4020: (8) .. versionchanged:: 1.13.0
4021: (11)     Tuples are allowed for keyword argument.
4022: (4) keepdims : bool, optional
4023: (8)     If this is set to True, the axes which are reduced are left
4024: (8)     in the result as dimensions with size one. With this option,
4025: (8)     the result will broadcast correctly against the original `array` .
4026: (8) .. versionadded:: 1.7.0
4027: (4) initial : scalar, optional
4028: (8)     The value with which to start the reduction.
4029: (8)     If the ufunc has no identity or the dtype is object, this defaults
4030: (8)     to None - otherwise it defaults to ufunc.identity.
4031: (8)     If ``None`` is given, the first element of the reduction is used,
4032: (8)     and an error is thrown if the reduction is empty.
4033: (8) .. versionadded:: 1.15.0
4034: (4) where : array_like of bool, optional
4035: (8)     A boolean array which is broadcasted to match the dimensions

```

```

4036: (8)          of `array`, and selects elements to include in the reduction. Note
4037: (8)          that for ufuncs like ``minimum`` that do not have an identity
4038: (8)          defined, one has to pass in also ``initial``.
4039: (8)          .. versionadded:: 1.17.0
4040: (4)          Returns
4041: (4)          -----
4042: (4)          r : ndarray
4043: (8)          The reduced array. If `out` was supplied, `r` is a reference to it.
4044: (4)          Examples
4045: (4)          -----
4046: (4)          >>> np.multiply.reduce([2,3,5])
4047: (4)          30
4048: (4)          A multi-dimensional array example:
4049: (4)          >>> X = np.arange(8).reshape((2,2,2))
4050: (4)          >>> X
4051: (4)          array([[[0, 1],
4052: (12)             [2, 3]],
4053: (11)               [[4, 5],
4054: (12)                 [6, 7]]])
4055: (4)          >>> np.add.reduce(X, 0)
4056: (4)          array([[ 4,  6],
4057: (11)             [ 8, 10]])
4058: (4)          >>> np.add.reduce(X) # confirm: default axis value is 0
4059: (4)          array([[ 4,  6],
4060: (11)             [ 8, 10]])
4061: (4)          >>> np.add.reduce(X, 1)
4062: (4)          array([[ 2,  4],
4063: (11)             [10, 12]])
4064: (4)          >>> np.add.reduce(X, 2)
4065: (4)          array([[ 1,  5],
4066: (11)             [ 9, 13]])
4067: (4)          You can use the ``initial`` keyword argument to initialize the reduction
4068: (4)          with a different value, and ``where`` to select specific elements to
4069: (4)          include:
4070: (4)          >>> np.add.reduce([10], initial=5)
4071: (4)          15
4072: (4)          >>> np.add.reduce(np.ones((2, 2, 2)), axis=(0, 2), initial=10)
4073: (4)          array([14., 14.])
4074: (4)          >>> a = np.array([10., np.nan, 10])
4075: (4)          >>> np.add.reduce(a, where=~np.isnan(a))
4076: (4)          20.0
4077: (4)          Allows reductions of empty arrays where they would normally fail, i.e.
4078: (4)          for ufuncs without an identity.
4079: (4)          >>> np.minimum.reduce([], initial=np.inf)
4080: (4)          inf
4081: (4)          >>> np.minimum.reduce([[1., 2.], [3., 4.]], initial=10., where=[True,
4082: (4)             False])
4083: (4)          array([ 1., 10.])
4084: (8)          ...
4085: (4)          ValueError: zero-size array to reduction operation minimum which has no
4086: (4)          identity
4087: (0)          """
4088: (4)          add_newdoc('numpy.core', 'ufunc', ('accumulate',
4089: (4)             """
4090: (4)             accumulate(array, axis=0, dtype=None, out=None)
4091: (4)             Accumulate the result of applying the operator to all elements.
4092: (6)             For a one-dimensional array, accumulate produces results equivalent to::
4093: (6)             r = np.empty(len(A))
4094: (6)             t = op.identity      # op = the ufunc being applied to A's elements
4095: (10)            for i in range(len(A)):
4096: (10)                t = op(t, A[i])
4097: (6)                r[i] = t
4098: (4)            return r
4099: (4)            For example, add.accumulate() is equivalent to np.cumsum().
4100: (4)            For a multi-dimensional array, accumulate is applied along only one
4101: (4)            axis (axis zero by default; see Examples below) so repeated use is

```

```

4102: (4)          Parameters
4103: (4)          -----
4104: (4)          array : array_like
4105: (8)          The array to act on.
4106: (4)          axis : int, optional
4107: (8)          The axis along which to apply the accumulation; default is zero.
4108: (4)          dtype : data-type code, optional
4109: (8)          The data-type used to represent the intermediate results. Defaults
4110: (8)          to the data-type of the output array if such is provided, or the
4111: (8)          data-type of the input array if no output array is provided.
4112: (4)          out : ndarray, None, or tuple of ndarray and None, optional
4113: (8)          A location into which the result is stored. If not provided or None,
4114: (8)          a freshly-allocated array is returned. For consistency with
4115: (8)          ``ufunc.__call__``, if given as a keyword, this may be wrapped in a
4116: (8)          1-element tuple.
4117: (8)          .. versionchanged:: 1.13.0
4118: (11)          Tuples are allowed for keyword argument.
4119: (4)          Returns
4120: (4)          -----
4121: (4)          r : ndarray
4122: (8)          The accumulated values. If `out` was supplied, `r` is a reference to
4123: (8)          `out`.
4124: (4)          Examples
4125: (4)          -----
4126: (4)          1-D array examples:
4127: (4)          >>> np.add.accumulate([2, 3, 5])
4128: (4)          array([ 2,  5, 10])
4129: (4)          >>> np.multiply.accumulate([2, 3, 5])
4130: (4)          array([ 2,  6, 30])
4131: (4)          2-D array examples:
4132: (4)          >>> I = np.eye(2)
4133: (4)          >>> I
4134: (4)          array([[1.,  0.],
4135: (11)          [0.,  1.]])
4136: (4)          Accumulate along axis 0 (rows), down columns:
4137: (4)          >>> np.add.accumulate(I, 0)
4138: (4)          array([[1.,  0.],
4139: (11)          [1.,  1.]])
4140: (4)          >>> np.add.accumulate(I) # no axis specified = axis zero
4141: (4)          array([[1.,  0.],
4142: (11)          [1.,  1.]])
4143: (4)          Accumulate along axis 1 (columns), through rows:
4144: (4)          >>> np.add.accumulate(I, 1)
4145: (4)          array([[1.,  1.],
4146: (11)          [0.,  1.]])
4147: (4)          """))
4148: (0)          add_newdoc('numpy.core', 'ufunc', ('reduceat',
4149: (4)          """
4150: (4)          reduceat(array, indices, axis=0, dtype=None, out=None)
4151: (4)          Performs a (local) reduce with specified slices over a single axis.
4152: (4)          For i in ``range(len(indices))``, `reduceat` computes
4153: (4)          ``ufunc.reduce(array[indices[i]:indices[i+1]])``, which becomes the i-th
4154: (4)          generalized "row" parallel to `axis` in the final result (i.e., in a
4155: (4)          2-D array, for example, if `axis = 0`, it becomes the i-th row, but if
4156: (4)          `axis = 1`, it becomes the i-th column). There are three exceptions to
4157: (4)          this:
4158: (6)          * when ``i = len(indices) - 1`` (so for the last index),
4159: (4)          ``indices[i+1] = array.shape[axis]``.
4160: (6)          * if ``indices[i] >= indices[i + 1]``, the i-th generalized "row" is
4161: (4)          simply ``array[indices[i]]``.
4162: (4)          * if ``indices[i] >= len(array)`` or ``indices[i] < 0``, an error is
4163: (4)          raised.
4164: (4)          The shape of the output depends on the size of `indices`, and may be
4165: (4)          larger than `array` (this happens if ``len(indices) >
4166: (4)          array.shape[axis]``).
4167: (8)          Parameters
4168: (4)          -----
4169: (4)          array : array_like
4170: (4)          The array to act on.

```

```

4168: (4)           indices : array_like
4169: (8)             Paired indices, comma separated (not colon), specifying slices to
4170: (8)             reduce.
4171: (4)           axis : int, optional
4172: (8)             The axis along which to apply the reduceat.
4173: (4)           dtype : data-type code, optional
4174: (8)             The type used to represent the intermediate results. Defaults
4175: (8)             to the data type of the output array if this is provided, or
4176: (8)             the data type of the input array if no output array is provided.
4177: (4)           out : ndarray, None, or tuple of ndarray and None, optional
4178: (8)             A location into which the result is stored. If not provided or None,
4179: (8)             a freshly-allocated array is returned. For consistency with
4180: (8)             ``ufunc.__call__``, if given as a keyword, this may be wrapped in a
4181: (8)             1-element tuple.
4182: (8)             .. versionchanged:: 1.13.0
4183: (11)            Tuples are allowed for keyword argument.
4184: (4)           Returns
4185: (4)           -----
4186: (4)           r : ndarray
4187: (8)             The reduced values. If `out` was supplied, `r` is a reference to
4188: (8)             `out`.
4189: (4)           Notes
4190: (4)           -----
4191: (4)             A descriptive example:
4192: (4)             If `array` is 1-D, the function `ufunc.accumulate(array)` is the same as
4193: (4)             ``ufunc.reduceat(array, indices)[::2]`` where `indices` is
4194: (4)             ``range(len(array) - 1)`` with a zero placed
4195: (4)             in every other element:
4196: (4)             ``indices = zeros(2 * len(array) - 1)``,
4197: (4)             ``indices[1::2] = range(1, len(array))``.
4198: (4)             Don't be fooled by this attribute's name: `reduceat(array)` is not
4199: (4)             necessarily smaller than `array`.
4200: (4)           Examples
4201: (4)           -----
4202: (4)             To take the running sum of four successive values:
4203: (4)             >>> np.add.reduceat(np.arange(8), [0,4, 1,5, 2,6, 3,7])[::2]
4204: (4)             array([ 6, 10, 14, 18])
4205: (4)             A 2-D example:
4206: (4)             >>> x = np.linspace(0, 15, 16).reshape(4,4)
4207: (4)             >>> x
4208: (4)             array([[ 0.,   1.,   2.,   3.],
4209: (11)               [ 4.,   5.,   6.,   7.],
4210: (11)               [ 8.,   9.,  10.,  11.],
4211: (11)               [12.,  13.,  14.,  15.]])
4212: (4)             :::
4213: (4)             >>> np.add.reduceat(x, [0, 3, 1, 2, 0])
4214: (4)             array([[12.,  15.,  18.,  21.],
4215: (11)               [12.,  13.,  14.,  15.],
4216: (11)               [ 4.,   5.,   6.,   7.],
4217: (11)               [ 8.,   9.,  10.,  11.],
4218: (11)               [24.,  28.,  32.,  36.]])
4219: (4)             :::
4220: (4)             >>> np.multiply.reduceat(x, [0, 3], 1)
4221: (4)             array([[ 0.,    3.],
4222: (11)               [120.,    7.],
4223: (11)               [720.,   11.],
4224: (11)               [2184.,  15.]])
4225: (4)             """))
4226: (0)           add_newdoc('numpy.core', 'ufunc', ('outer',
4227: (4)             """
4228: (4)             outer(A, B, /, **kwargs)
4229: (4)             Apply the ufunc `op` to all pairs (a, b) with a in `A` and b in `B`.
4230: (4)             Let ``M = A.ndim``, ``N = B.ndim``. Then the result, `C`, of
4231: (4)             ``op.outer(A, B)`` is an array of dimension M + N such that:
4232: (4)             .. math:: C[i_0, \dots, i_{M-1}, j_0, \dots, j_{N-1}] =
4233: (7)               op(A[i_0, \dots, i_{M-1}], B[j_0, \dots, j_{N-1}])
4234: (4)             For `A` and `B` one-dimensional, this is equivalent to:
4235: (6)               r = empty(len(A),len(B))
4236: (6)               for i in range(len(A)):

        for j in range(len(B)):
            r[i,j] = op(A[i], B[j]) # op = ufunc in question

    Parameters
    -----
    A : array_like
        First array
    B : array_like
        Second array
    kwargs : any
        Arguments to pass on to the ufunc. Typically `dtype` or `out`.
        See `ufunc` for a comprehensive overview of all available arguments.

    Returns
    -----
    r : ndarray
        Output array

    See Also
    -----
    numpy.outer : A less powerful version of ``np.multiply.outer`` that `ravel`\ s all inputs to 1D. This exists primarily for compatibility with old code.
    tensordot : ``np.tensordot(a, b, axes=((), ()))`` and ``np.multiply.outer(a, b)`` behave same for all dimensions of a and b.

    Examples
    -----
    >>> np.multiply.outer([1, 2, 3], [4, 5, 6])
    array([[ 4,  5,  6],
           [ 8, 10, 12],
           [12, 15, 18]])

    A multi-dimensional example:
    >>> A = np.array([[1, 2, 3], [4, 5, 6]])
    >>> A.shape
    (2, 3)
    >>> B = np.array([[1, 2, 3, 4]])
    >>> B.shape
    (1, 4)
    >>> C = np.multiply.outer(A, B)
    >>> C.shape; C
    (2, 3, 1, 4)
    array([[[[ 1,  2,  3,  4]],
           [[ 2,  4,  6,  8]],
           [[ 3,  6,  9, 12]]],
           [[[ 4,  8, 12, 16]],
           [[ 5, 10, 15, 20]],
           [[ 6, 12, 18, 24]]])

    add_newdoc('numpy.core', 'ufunc', ('at',
    """
        at(a, indices, b=None, /)
        Performs unbuffered in place operation on operand 'a' for elements specified by 'indices'. For addition ufunc, this method is equivalent to ``a[indices] += b``, except that results are accumulated for elements that are indexed more than once. For example, ``a[[0,0]] += 1`` will only increment the first element once because of buffering, whereas ``add.at(a, [0,0], 1)`` will increment the first element twice.
        .. versionadded:: 1.8.0
    Parameters
    -----
    a : array_like
        The array to perform in place operation on.
    indices : array_like or tuple
        Array like index object or slice object for indexing into first operand. If first operand has multiple dimensions, indices can be a tuple of array like index objects or slice objects.
    b : array_like
        Second operand for ufuncs requiring two operands. Operand must be broadcastable over first operand after indexing or slicing.

    Examples
    -----

```

```

4306: (4) Set items 0 and 1 to their negative values:
4307: (4) >>> a = np.array([1, 2, 3, 4])
4308: (4) >>> np.negative.at(a, [0, 1])
4309: (4) >>> a
4310: (4) array([-1, -2,  3,  4])
4311: (4) Increment items 0 and 1, and increment item 2 twice:
4312: (4) >>> a = np.array([1, 2, 3, 4])
4313: (4) >>> np.add.at(a, [0, 1, 2, 2], 1)
4314: (4) >>> a
4315: (4) array([2, 3, 5, 4])

4318: (4) >>> a = np.array([1, 2, 3, 4])
4319: (4) >>> b = np.array([1, 2])
4320: (4) >>> np.add.at(a, [0, 1], b)
4321: (4) >>> a
4322: (4) array([2, 4, 3, 4])
4323: (4) """
4324: (0) add_newdoc('numpy.core', 'ufunc', ('resolve_dtypes',
4325: (4) """
4326: (4) resolve_dtypes(dtypes, *, signature=None, casting=None, reduction=False)
4327: (4) Find the dtypes NumPy will use for the operation. Both input and
4328: (4) output dtypes are returned and may differ from those provided.
4329: (4) .. note::
4330: (8) This function always applies NEP 50 rules since it is not provided
4331: (8) any actual values. The Python types ``int``, ``float``, and
4332: (8) ``complex`` thus behave weak and should be passed for "untyped"
4333: (8) Python input.
4334: (4) Parameters
4335: (4) -----
4336: (4) dtypes : tuple of dtypes, None, or literal int, float, complex
4337: (8) The input dtypes for each operand. Output operands can be
4338: (8) None, indicating that the dtype must be found.
4339: (4) signature : tuple of DTypes or None, optional
4340: (8) If given, enforces exact Dtype (classes) of the specific operand.
4341: (8) The ufunc ``dtype`` argument is equivalent to passing a tuple with
4342: (8) only output dtypes set.
4343: (4) casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
4344: (8) The casting mode when casting is necessary. This is identical to
4345: (8) the ufunc call casting modes.
4346: (4) reduction : boolean
4347: (8) If given, the resolution assumes a reduce operation is happening
4348: (8) which slightly changes the promotion and type resolution rules.
4349: (8) `dtypes` is usually something like ``(``None, np.dtype("i2"), None)``
4350: (8) for reductions (first input is also the output).
4351: (8) .. note::
4352: (12) The default casting mode is "same_kind", however, as of
4353: (12) NumPy 1.24, NumPy uses "unsafe" for reductions.
4354: (4) Returns
4355: (4) -----
4356: (4) dtypes : tuple of dtypes
4357: (8) The dtypes which NumPy would use for the calculation. Note that
4358: (8) dtypes may not match the passed in ones (casting is necessary).
4359: (4) See Also
4360: (4) -----
4361: (4) numpy.ufunc._resolve_dtypes_and_context :
4362: (8) Similar function to this, but returns additional information which
4363: (8) give access to the core C functionality of NumPy.
4364: (4) Examples
4365: (4) -----
4366: (4) This API requires passing dtypes, define them for convenience:
4367: (4) >>> int32 = np.dtype("int32")
4368: (4) >>> float32 = np.dtype("float32")
4369: (4) The typical ufunc call does not pass an output dtype. `np.add` has two
4370: (4) inputs and one output, so leave the output as ``None`` (not provided):
4371: (4) >>> np.add.resolve_dtypes((int32, float32, None))
4372: (4) (dtype('float64'), dtype('float64'), dtype('float64'))
4373: (4) The loop found uses "float64" for all operands (including the output), the
4374: (4) first input would be cast.

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

4375: (4) ``resolve_dtypes`` supports "weak" handling for Python scalars by passing
4376: (4) ``int``, ``float``, or ``complex``:
4377: (4) >>> np.add.resolve_dtypes((float32, float, None))
4378: (4) (dtype('float32'), dtype('float32'), dtype('float32'))
4379: (4) Where the Python ``float`` behaves similar to a Python value ``0.0``
4380: (4) in a ufunc call. (See :ref:`NEP 50 <NEP50>` for details.)
4381: (4) """
4382: (0) add_newdoc('numpy.core', 'ufunc', ('_resolve_dtypes_and_context',
4383: (4) """
4384: (4) _resolve_dtypes_and_context(dtypes, *, signature=None, casting=None,
reduction=False)
4385: (4) See `numpy.ufunc.resolve_dtypes` for parameter information. This
4386: (4) function is considered *unstable*. You may use it, but the returned
4387: (4) information is NumPy version specific and expected to change.
4388: (4) Large API/ABI changes are not expected, but a new NumPy version is
4389: (4) expected to require updating code using this functionality.
4390: (4) This function is designed to be used in conjunction with
4391: (4) `numpy.ufunc._get_strided_loop`. The calls are split to mirror the C API
4392: (4) and allow future improvements.
4393: (4) Returns
4394: (4) -----
4395: (4) dtypes : tuple of dtypes
4396: (4) call_info :
4397: (8) PyCapsule with all necessary information to get access to low level
4398: (8) C calls. See `numpy.ufunc._get_strided_loop` for more information.
4399: (4) """
4400: (0) add_newdoc('numpy.core', 'ufunc', ('_get_strided_loop',
4401: (4) """
4402: (4) _get_strided_loop(call_info, /, *, fixed_strides=None)
4403: (4) This function fills in the ``call_info`` capsule to include all
4404: (4) information necessary to call the low-level strided loop from NumPy.
4405: (4) See notes for more information.
4406: (4) Parameters
4407: (4) -----
4408: (4) call_info : PyCapsule
4409: (8) The PyCapsule returned by `numpy.ufunc._resolve_dtypes_and_context`.
4410: (4) fixed_strides : tuple of int or None, optional
4411: (8) A tuple with fixed byte strides of all input arrays. NumPy may use
4412: (8) this information to find specialized loops, so any call must follow
4413: (8) the given stride. Use ``None`` to indicate that the stride is not
4414: (8) known (or not fixed) for all calls.
4415: (4) Notes
4416: (4) -----
4417: (4) Together with `numpy.ufunc._resolve_dtypes_and_context` this function
4418: (4) gives low-level access to the NumPy ufunc loops.
4419: (4) The first function does general preparation and returns the required
4420: (4) information. It returns this as a C capsule with the version specific
4421: (4) name ``numpy_1.24_ufunc_call_info``.
4422: (4) The NumPy 1.24 ufunc call info capsule has the following layout::
4423: (8) typedef struct {
4424: (12)     PyArrayMethod_StridedLoop *strided_loop;
4425: (12)     PyArrayMethod_Context *context;
4426: (12)     NpyAuxData *auxdata;
4427: (12)     /* Flag information (expected to change) */
4428: (12)     npy_bool requires_pyapi; /* GIL is required by loop */
4429: (12)     /* Loop doesn't set FPE flags; if not set check FPE flags */
4430: (12)     npy_bool no_floatingpoint_errors;
4431: (8) } ufunc_call_info;
4432: (4) Note that the first call only fills in the ``context``. The call to
4433: (4) ``_get_strided_loop`` fills in all other data.
4434: (4) Please see the ``numpy/experimental_dtype_api.h`` header for exact
4435: (4) call information; the main thing to note is that the new-style loops
4436: (4) return 0 on success, -1 on failure. They are passed context as new
4437: (4) first input and ``auxdata`` as (replaced) last.
4438: (4) Only the ``strided_loop`` signature is considered guaranteed stable
4439: (4) for NumPy bug-fix releases. All other API is tied to the experimental
4440: (4) API versioning.
4441: (4) The reason for the split call is that cast information is required to
4442: (4) decide what the fixed-strides will be.

```

```

4443: (4)           NumPy ties the lifetime of the ``auxdata`` information to the capsule.
4444: (4)           """
4445: (0)           add_newdoc('numpy.core.multiarray', 'dtype',
4446: (4)           """
4447: (4)           dtype(dtype, align=False, copy=False, [metadata])
4448: (4)           Create a data type object.
4449: (4)           A numpy array is homogeneous, and contains elements described by a
4450: (4)           dtype object. A dtype object can be constructed from different
4451: (4)           combinations of fundamental numeric types.
4452: (4)           Parameters
4453: (4)           -----
4454: (4)           dtype
4455: (8)           Object to be converted to a data type object.
4456: (4)           align : bool, optional
4457: (8)           Add padding to the fields to match what a C compiler would output
4458: (8)           for a similar C-struct. Can be ``True`` only if `obj` is a dictionary
4459: (8)           or a comma-separated string. If a struct dtype is being created,
4460: (8)           this also sets a sticky alignment flag ``isalignedstruct``.
4461: (4)           copy : bool, optional
4462: (8)           Make a new copy of the data-type object. If ``False``, the result
4463: (8)           may just be a reference to a built-in data-type object.
4464: (4)           metadata : dict, optional
4465: (8)           An optional dictionary with dtype metadata.
4466: (4)           See also
4467: (4)           -----
4468: (4)           result_type
4469: (4)           Examples
4470: (4)           -----
4471: (4)           Using array-scalar type:
4472: (4)           >>> np.dtype(np.int16)
4473: (4)           dtype('int16')
4474: (4)           Structured type, one field name 'f1', containing int16:
4475: (4)           >>> np.dtype([('f1', np.int16)])
4476: (4)           dtype([('f1', '<i2')])
4477: (4)           Structured type, one field named 'f1', in itself containing a structured
4478: (4)           type with one field:
4479: (4)           >>> np.dtype([('f1', [('f1', np.int16)]))]
4480: (4)           dtype([('f1', [('f1', '<i2')])])
4481: (4)           Structured type, two fields: the first field contains an unsigned int, the
4482: (4)           second an int32:
4483: (4)           >>> np.dtype([('f1', np.uint64), ('f2', np.int32)])
4484: (4)           dtype([('f1', '<u8'), ('f2', '<i4')])
4485: (4)           Using array-protocol type strings:
4486: (4)           >>> np.dtype([('a','f8'),('b','S10')])
4487: (4)           dtype([('a', '<f8'), ('b', 'S10')])
4488: (4)           Using comma-separated field formats. The shape is (2,3):
4489: (4)           >>> np.dtype("i4, (2,3)f8")
4490: (4)           dtype([('f0', '<i4'), ('f1', '<f8', (2, 3))])
4491: (4)           Using tuples. ``int`` is a fixed type, 3 the field's shape. ``void``
4492: (4)           is a flexible type, here of size 10:
4493: (4)           >>> np.dtype([('hello',(np.int64,3)),('world',np void,10)])
4494: (4)           dtype([('hello', '<i8', (3,)), ('world', 'V10')])
4495: (4)           Subdivide ``int16`` into 2 ``int8``'s, called x and y. 0 and 1 are
4496: (4)           the offsets in bytes:
4497: (4)           >>> np.dtype((np.int16, {'x':(np.int8,0), 'y':(np.int8,1)}))
4498: (4)           dtype((numpy.int16, [('x', 'i1'), ('y', 'i1')]))
4499: (4)           Using dictionaries. Two fields named 'gender' and 'age':
4500: (4)           >>> np.dtype({'names':['gender','age'], 'formats':['S1',np.uint8]})
4501: (4)           dtype([('gender', 'S1'), ('age', 'u1')])
4502: (4)           Offsets in bytes, here 0 and 25:
4503: (4)           >>> np.dtype({'surname':('S25',0), 'age':(np.uint8,25)})
4504: (4)           dtype([('surname', 'S25'), ('age', 'u1')])
4505: (4)           """
4506: (0)           add_newdoc('numpy.core.multiarray', 'dtype', ('alignment',
4507: (4)           """
4508: (4)           The required alignment (bytes) of this data-type according to the
compiler.
4509: (4)           More information is available in the C-API section of the manual.
4510: (4)           Examples

```

```

4511: (4)      -----
4512: (4)      >>> x = np.dtype('i4')
4513: (4)      >>> x.alignment
4514: (4)      4
4515: (4)      >>> x = np.dtype(float)
4516: (4)      >>> x.alignment
4517: (4)      8
4518: (4)      "'''")
4519: (0)      add_newdoc('numpy.core.multiarray', 'dtype', ('byteorder',
4520: (4)      """
4521: (4)          A character indicating the byte-order of this data-type object.
4522: (4)          One of:
4523: (4)          === =====
4524: (4)          '=' native
4525: (4)          '<' little-endian
4526: (4)          '>' big-endian
4527: (4)          '|' not applicable
4528: (4)          === =====
4529: (4)          All built-in data-type objects have byteorder either '=' or '|'.
4530: (4)          Examples
4531: (4)          -----
4532: (4)          >>> dt = np.dtype('i2')
4533: (4)          >>> dt.byteorder
4534: (4)          '='
4535: (4)          >>> # endian is not relevant for 8 bit numbers
4536: (4)          >>> np.dtype('i1').byteorder
4537: (4)          '|'
4538: (4)          >>> # or ASCII strings
4539: (4)          >>> np.dtype('S2').byteorder
4540: (4)          '|'
4541: (4)          >>> # Even if specific code is given, and it is native
4542: (4)          >>> # '=' is the byteorder
4543: (4)          >>> import sys
4544: (4)          >>> sys_is_le = sys.byteorder == 'little'
4545: (4)          >>> native_code = '<' if sys_is_le else '>'
4546: (4)          >>> swapped_code = '>' if sys_is_le else '<'
4547: (4)          >>> dt = np.dtype(native_code + 'i2')
4548: (4)          >>> dt.byteorder
4549: (4)          '='
4550: (4)          >>> # Swapped code shows up as itself
4551: (4)          >>> dt = np.dtype(swapped_code + 'i2')
4552: (4)          >>> dt.byteorder == swapped_code
4553: (4)          True
4554: (4)          "'''")
4555: (0)      add_newdoc('numpy.core.multiarray', 'dtype', ('char',
4556: (4)          """A unique character code for each of the 21 different built-in types.
4557: (4)          Examples
4558: (4)          -----
4559: (4)          >>> x = np.dtype(float)
4560: (4)          >>> x.char
4561: (4)          'd'
4562: (4)          "'''")
4563: (0)      add_newdoc('numpy.core.multiarray', 'dtype', ('descr',
4564: (4)          """
4565: (4)          `__array_interface__` description of the data-type.
4566: (4)          The format is that required by the 'descr' key in the
4567: (4)          `__array_interface__` attribute.
4568: (4)          Warning: This attribute exists specifically for `__array_interface__`,
4569: (4)          and passing it directly to `np.dtype` will not accurately reconstruct
4570: (4)          some dtypes (e.g., scalar and subarray dtypes).
4571: (4)          Examples
4572: (4)          -----
4573: (4)          >>> x = np.dtype(float)
4574: (4)          >>> x.descr
4575: (4)          [('', '<f8')]
4576: (4)          >>> dt = np.dtype([('name', np.str_, 16), ('grades', np.float64, (2,))])
4577: (4)          >>> dt.descr
4578: (4)          [('name', '<U16'), ('grades', '<f8', (2,))]
4579: (4)          "'''")

add_newdoc('numpy.core.multiarray', 'dtype', ('fields',
"")
Dictionary of named fields defined for this data type, or ``None``.
The dictionary is indexed by keys that are the names of the fields.
Each entry in the dictionary is a tuple fully describing the field::
    (dtype, offset[, title])
Offset is limited to C int, which is signed and usually 32 bits.
If present, the optional title can be any object (if it is a string
or unicode then it will also be a key in the fields dictionary,
otherwise it's meta-data). Notice also that the first two elements
of the tuple can be passed directly as arguments to the
`ndarray.getfield` and `ndarray.setfield` methods.

add_newdoc('numpy.core.multiarray', 'dtype', ('flags',
"")
Bit-flags describing how this data type is to be interpreted.
Bit-masks are in `numpy.core.multiarray` as the constants
`ITEM_HASOBJECT`, `LIST_PICKLE`, `ITEM_IS_POINTER`, `NEEDS_INIT`,
`NEEDS_PYAPI`, `USE_GETITEM`, `USE_SETITEM`. A full explanation
of these flags is in C-API documentation; they are largely useful
for user-defined data-types.
The following example demonstrates that operations on this particular
dtype requires Python C-API.
Examples
-----
>>> x = np.dtype([('a', np.int32, 8), ('b', np.float64, 6)])
>>> x.flags
16
>>> np.core.multiarray.NEEDS_PYAPI
16

4702: (4)          'i'
4703: (4)          >>> dt = np.dtype('f8')
4704: (4)          >>> dt.kind
4705: (4)          'f'
4706: (4)          >>> dt = np.dtype([('field1', 'f8')])
4707: (4)          >>> dt.kind
4708: (4)          'V'
4709: (0)          """
4710: (4)          add_newdoc('numpy.core.multiarray', 'dtype', ('metadata',
4711: (4)          """
4712: (4)          Either ``None`` or a readonly dictionary of metadata (mappingproxy).
4713: (4)          The metadata field can be set using any dictionary at data-type
4714: (4)          creation. NumPy currently has no uniform approach to propagating

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

4714: (4)           metadata; although some array operations preserve it, there is no
4715: (4)           guarantee that others will.
4716: (4)
4717: (8)           .. warning::
4718: (8)             Although used in certain projects, this feature was long undocumented
4719: (8)             and is not well supported. Some aspects of metadata propagation
4720: (4)             are expected to change in the future.
4721: (4)
4722: (4)           Examples
4723: (4)           -----
4724: (4)             >>> dt = np.dtype(float, metadata={"key": "value"})
4725: (4)             >>> dt.metadata["key"]
4726: (4)               'value'
4727: (4)             >>> arr = np.array([1, 2, 3], dtype=dt)
4728: (4)             >>> arr.dtype.metadata
4729: (4)               mappingproxy({'key': 'value'})
4730: (4)             Adding arrays with identical datatypes currently preserves the metadata:
4731: (4)             >>> (arr + arr).dtype.metadata
4732: (4)               mappingproxy({'key': 'value'})
4733: (4)             But if the arrays have different dtype metadata, the metadata may be
4734: (4)             dropped:
4735: (4)             >>> dt2 = np.dtype(float, metadata={"key2": "value2"})
4736: (4)             >>> arr2 = np.array([3, 2, 1], dtype=dt2)
4737: (4)             >>> (arr + arr2).dtype.metadata is None
4738: (0)               True # The metadata field is cleared so None is returned
4739: (4)
4740: (4)             add_newdoc('numpy.core.multiarray', 'dtype', ('name',
4741: (4)               """
4742: (4)                 A bit-width name for this data-type.

4960: (4) busdaycalendar(weekmask='1111100', holidays=None)
4961: (4) A business day calendar object that efficiently stores information
4962: (4) defining valid days for the busday family of functions.
4963: (4) The default valid days are Monday through Friday ("business days").
4964: (4) A busdaycalendar object can be specified with any set of weekly
4965: (4) valid days, plus an optional "holiday" dates that always will be invalid.
4966: (4) Once a busdaycalendar object is created, the weekmask and holidays
4967: (4) cannot be modified.
4968: (4) .. versionadded:: 1.7.0
4969: (4) Parameters
4970: (4) -----
4971: (4) weekmask : str or array_like of bool, optional
4972: (8) A seven-element array indicating which of Monday through Sunday are
4973: (8) valid days. May be specified as a length-seven list or array, like
4974: (8) [1,1,1,1,1,0,0]; a length-seven string, like '1111100'; or a string
4975: (8) like "Mon Tue Wed Thu Fri", made up of 3-character abbreviations for
4976: (8) weekdays, optionally separated by white space. Valid abbreviations
4977: (8) are: Mon Tue Wed Thu Fri Sat Sun
4978: (4) holidays : array_like of datetime64[D], optional
4979: (8) An array of dates to consider as invalid dates, no matter which
4980: (8) weekday they fall upon. Holiday dates may be specified in any
4981: (8) order, and NaT (not-a-time) dates are ignored. This list is
4982: (8) saved in a normalized form that is suited for fast calculations
4983: (8) of valid days.
4984: (4) Returns
4985: (4) -----
4986: (4) out : busdaycalendar
4987: (8) A business day calendar object containing the specified
4988: (8) weekmask and holidays values.

    add_newdoc('numpy.core.multiarray', 'datetime_data',
               """
               datetime_data(dtype, /)
               Get information about the step size of a date or time type.
               The returned tuple can be passed as the second argument of
               `numpy.datetime64` and
               `numpy.timedelta64` .
               Parameters
               -----
               dtype : dtype
                   The dtype object, which must be a `datetime64` or `timedelta64` type.
               Returns
               -----
               unit : str
                   The :ref:`datetime unit <arrays.dtypes.dateunits>` on which this dtype
                   is based.
               count : int
                   The number of base units in a step.
               Examples
               -----
               >>> dt_25s = np.dtype('timedelta64[25s]')
               >>> np.datetime_data(dt_25s)
               ('s', 25)
               >>> np.array(10, dt_25s).astype('timedelta64[s]')
               array(250, dtype='timedelta64[s]')
               The result can be used to construct a datetime that uses the same units
               as a timedelta
               >>> np.datetime64('2010', np.datetime_data(dt_25s))
               numpy.datetime64('2010-01-01T00:00:00', '25s')
               """)

        """
add_newdoc_for_scalar_type('void', [],
                           r"""
        np.void(length_or_data, /, dtype=None)
        Create a new structured or unstructured void scalar.
        Parameters
        -----
        length_or_data : int, array-like, bytes-like, object
            One of multiple meanings (see notes). The length or
            bytes data of an unstructured void. Or alternatively,
            the data to be stored in the new scalar when `dtype`
            is provided.
        This can be an array-like, in which case an array may
        be returned.
        dtype : dtype, optional
            If provided the dtype of the new scalar. This dtype must
            be "void" dtype (i.e. a structured or unstructured void,
            see also :ref:`defining-structured-types`).
        ..versionadded:: 1.24
        Notes
        -----
        For historical reasons and because void scalars can represent both
        arbitrary byte data and structured dtypes, the void constructor
        has three calling conventions:
        1. ``np.void(5)`` creates a ``dtype="V5"`` scalar filled with five
           ``\0`` bytes. The 5 can be a Python or NumPy integer.
        2. ``np.void(b"bytes-like")`` creates a void scalar from the byte string.
           The dtype itemsize will match the byte string length, here ``"V10"``.
        3. When a ``dtype=`` is passed the call is roughly the same as an
           array creation. However, a void scalar rather than array is returned.
           Please see the examples which show all three different conventions.

```

```

209: (4)          Examples
210: (4)          -----
211: (4)          >>> np.void(5)
212: (4)          void(b'\x00\x00\x00\x00\x00\x00')

        Creates a string repr of the dtype, excluding the 'dtype()' part
        surrounding the object. This object may be a string, a list, or
        a dict depending on the nature of the dtype. This
        is the object passed as the first parameter to the dtype
        constructor, and if no additional constructor parameters are
        given, will reproduce the exact memory layout.
        Parameters
        -----
        short : bool
            If true, this creates a shorter repr using 'kind' and 'itemsize',
            instead
            of the longer type name.
        include_align : bool
            If true, this includes the 'align=True' parameter
            inside the struct dtype construction dict when needed. Use this flag
            if you want a proper repr string without the 'dtype()' part around it.
            If false, this does not preserve the
            'align=True' parameter or sticky NPY_ALIGNED_STRUCT flag for
            struct arrays like the regular repr does, because the 'align'
            flag is not part of first dtype constructor parameter. This
            mode is intended for a full 'repr', where the 'align=True' is
    """

## File 64 - \_dtype\_ctypes.py:

```

1: (0)             """
2: (0)             Conversion from ctypes to dtype.
3: (0)             In an ideal world, we could achieve this through the PEP3118 buffer protocol,
4: (0)             something like::
5: (4)                 def dtype_from_ctypes_type(t):
6: (8)                     class DummyStruct(ctypes.Structure):
7: (12)                         __fields__ = [('a', t)]
8: (8)                         ctype_0 = (DummyStruct * 0)()
9: (8)                         mv = memoryview(ctype_0)
10: (8)                         return _dtype_from_pep3118(mv.format)[ 'a' ]
11: (0)             Unfortunately, this fails because:
12: (0)                 * ctypes cannot handle length-0 arrays with PEP3118 (bpo-32782)
13: (0)                 * PEP3118 cannot represent unions, but both numpy and ctypes can
14: (0)                 * ctypes cannot handle big-endian structs with PEP3118 (bpo-32780)

```

49: (8)                     Same as `eps`.
50: (4)                 tiny : float
51: (8)                     An alias for `smallest_normal`, kept for backwards compatibility.
52: (4)                 huge : float
53: (8)                     Same as `xmax`.
54: (4)                 precision : float
55: (8)                     ``- int(-log10(eps))``
56: (4)                 resolution : float
57: (8)                     ``- 10**(-precision)``
58: (4)                 smallest_normal : float
59: (8)                     The smallest positive floating point number with 1 as leading bit in
60: (8)                         the mantissa following IEEE-754. Same as `xmin`.
61: (4)                 smallest_subnormal : float
62: (8)                     The smallest positive floating point number with 0 as leading bit in
63: (8)                         the mantissa following IEEE-754.
64: (4)                 Parameters
65: (4)                 -----
66: (4)                 float_conv : function, optional
67: (8)                     Function that converts an integer or integer array to a float
68: (8)                         or float array. Default is `float`.
69: (4)                 int_conv : function, optional
70: (8)                     Function that converts a float or float array to an integer or
71: (8)                         integer array. Default is `int`.
72: (4)                 float_to_float : function, optional
73: (8)                     Function that converts a float array to float. Default is `float`.
74: (8)                     Note that this does not seem to do anything useful in the current
75: (8)                         implementation.

```

```

76: (4)          float_to_str : function, optional
77: (8)            Function that converts a single float to a string. Default is
78: (8)              ``lambda v:'%24.16e' %v``.
79: (4)          title : str, optional
80: (8)            Title that is printed in the string representation of `MachAr`.

    """
    Set how floating-point errors are handled.
    Note that operations on integer scalar types (such as `int16`) are
    handled like floating point, and are affected by these settings.
    Parameters
    -----
    all : {'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional
        Set treatment for all types of floating-point errors at once:
        - ignore: Take no action when the exception occurs.
        - warn: Print a `RuntimeWarning` (via the Python `warnings` module).
        - raise: Raise a `FloatingPointError`.
        - call: Call a function specified using the `seterrcall` function.
        - print: Print a warning directly to ``stdout``.
        - log: Record error in a Log object specified by `seterrcall`.
    The default is not to change the current behavior.
    divide : {'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional
        Treatment for division by zero.
    over : {'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional
        Treatment for floating-point overflow.
    under : {'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional
        Treatment for floating-point underflow.
    invalid : {'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional
        Treatment for invalid floating-point operation.
    Returns
    -----
    old_settings : dict
        Dictionary containing the old settings.
    See also
    -----
    seterrcall : Set a callback function for the 'call' mode.
    geterr, geterrcall, errstate
    Notes
    -----
    The floating-point exceptions are defined in the IEEE 754 standard [1]_:
    - Division by zero: infinite result obtained from finite numbers.
    - Overflow: result too large to be expressed.
    - Underflow: result so close to zero that some precision
        was lost.
    - Invalid operation: result is not an expressible number, typically
        indicates that a NaN was produced.
    .. [1] https://en.wikipedia.org/wiki/IEEE\_754
    Examples
    -----
    >>> old_settings = np.seterr(all='ignore') #seterr to known value
    >>> np.seterr(over='raise')
    {'divide': 'ignore', 'over': 'ignore', 'under': 'ignore', 'invalid':
    'ignore'}

179: (0) def seterrcall(func):
180: (4)     """
181: (4)         Set the floating-point error callback function or log object.
182: (4)         There are two ways to capture floating-point error messages. The first
183: (4)         is to set the error-handler to 'call', using `seterr`. Then, set
184: (4)         the function to call using this function.
185: (4)         The second is to set the error-handler to 'log', using `seterr`.
186: (4)         Floating-point errors then trigger a call to the 'write' method of
187: (4)         the provided object.
188: (4)         Parameters
189: (4)         -----
190: (4)         func : callable f(err, flag) or object with write method
191: (8)             Function to call upon floating-point errors ('call'-mode) or
192: (8)             object whose 'write' method is used to log such message ('log'-mode).
193: (8)
describing
194: (8)             The call function takes two arguments. The first is a string
195: (8)
196: (8)             the type of error (such as "divide by zero", "overflow", "underflow",
one
197: (8)                 or "invalid value"), and the second is the status flag. The flag is a
198: (10)                 byte, whose four least-significant bits indicate the type of error,
of "divide", "over", "under", "invalid"::
199: (8)                 [0 0 0 0 divide over under invalid]
200: (8)                 In other words, ``flags = divide + 2*over + 4*under + 8*invalid``.
201: (8)                 If an object is provided, its write method should take one argument,
a string.
202: (4)             Returns
203: (4)             -----
204: (4)             h : callable, log instance or None
205: (8)                 The old error handler.

291: (4)               errstate(**kwargs)
292: (4)               Context manager for floating-point error handling.
293: (4)               Using an instance of `errstate` as a context manager allows statements in
294: (4)               that context to execute with a known error handling behavior. Upon
entering
295: (4)               the context the error handling is set with `seterr` and `seterrcall`, and
296: (4)               upon exiting it is reset to what it was before.
297: (4)               .. versionchanged:: 1.17.0
298: (8)                   `errstate` is also usable as a function decorator, saving
299: (8)                   a level of indentation if an entire function is wrapped.
300: (8)                   See :py:class:`contextlib.ContextDecorator` for more information.
301: (4)           Parameters
302: (4)           -----
303: (4)           kwargs : {divide, over, under, invalid}
304: (8)               Keyword arguments. The valid keywords are the possible floating-point
305: (8)               exceptions. Each keyword should have a string value that defines the
306: (8)               treatment for the particular error. Possible values are
307: (8)               {'ignore', 'warn', 'raise', 'call', 'print', 'log'}.
308: (4)           See Also
