41: (0) files>
42: (6)
43: (0) 3) To generate signature files:
44: (13)     f2py -h <filename.pyf> ...< same options as in (1) >
45: (13) Description: This program generates a Python C/API file (<modulename>module.c)
46: (13) that contains wrappers for given fortran functions so that they
47: (0) can be called from Python. With the -c option the corresponding
47: (0) extension modules are built.
48: (2) Options:
49: (19)     -h <filename> Write signatures of the fortran routines to file <filename>
50: (19)             and exit. You can then edit <filename> and use it instead
51: (19)             of <fortran files>. If <filename>==stdout then the
52: (2)             signatures are printed to stdout.
53: (19)             <fortran functions> Names of fortran routines for which Python C/API
54: (19)             functions will be generated. Default is all that are found
55: (2)             in <fortran files>.
56: (19)             <fortran files> Paths to fortran/signature files that will be scanned for
57: (2)             <fortran functions> in order to determine their signatures.
58: (2)             skip: Ignore fortran functions that follow until `:'.
59: (2)             only: Use only fortran functions that follow until `:'.
60: (2)             : Get back to <fortran files> mode.
61: (19)             -m <modulename> Name of the module; f2py generates a Python/C API
62: (19)             file <modulename>module.c or extension module <modulename>.
63: (2)             Default is 'untitled'.
64: (22)             '-include<header>' Writes additional headers in the C wrapper, can be
65: (2)                 multiple times, generates #include <header> each time.
66: (19)             --[no-]lower Do [not] lower the cases in <fortran files>. By default,
key.               --lower is assumed with -h key, and --no-lower without -h
67: (2)             --build-dir <dirname> All f2py generated files are created in <dirname>.

```

```

68: (19)                               Default is tempfile.mkdtemp().
69: (2) --overwrite-signature Overwrite existing signature file.
70: (2) --[no-]latex-doc Create (or not) <modulename>module.tex.
71: (19)                               Default is --no-latex-doc.
72: (2) --short-latex Create 'incomplete' LaTeX document (without commands
73: (19)                               \\documentclass, \\tableofcontents, and
\\begin{{document}},                                \\end{{document}}).
74: (19) --[no-]rest-doc Create (or not) <modulename>module.rst.
75: (2)                               Default is --no-rest-doc.
76: (19) --debug-capi Create C/API code that reports the state of the wrappers
77: (2)                               during runtime. Useful for debugging.
78: (19) --[no-]wrap-functions Create Fortran subroutine wrappers to Fortran 77
79: (2)                               functions. --wrap-functions is default because it ensures
80: (19)                               maximum portability/compiler independence.
81: (19) --include-paths <path1>:<path2>:... Search include files from the given
82: (2)                               directories.
83: (19) --help-link [...] List system resources found by system_info.py. See also
84: (2)                               --link-<resource> switch below. [...] is optional list
85: (19)                               of resources names. E.g. try 'f2py --help-link lapack_opt'.
86: (19) --f2cmap <filename> Load Fortran-to-Python KIND specification from the
87: (2)                               given
88: (19)                               file. Default: .f2py_f2cmap in current directory.
89: (2) --quiet Run quietly.
90: (2) --verbose Run with extra verbosity.
91: (2) --skip-empty-wrappers Only generate wrapper files when needed.
92: (2) -v Print f2py version ID and exit.
93: (0) build backend options (only effective with -c)
94: (0) [NO_MESON] is used to indicate an option not meant to be used
95: (0) with the meson backend or above Python 3.12:
96: (2) --fcompiler= Specify Fortran compiler type by vendor [NO_MESON]
97: (2) --compiler= Specify distutils C compiler type [NO_MESON]
98: (2) --help-fcompiler List available Fortran compilers and exit [NO_MESON]
99: (2) --f77exec= Specify the path to F77 compiler [NO_MESON]
100: (2) --f90exec= Specify the path to F90 compiler [NO_MESON]
101: (2) --f77flags= Specify F77 compiler flags
102: (2) --f90flags= Specify F90 compiler flags
103: (2) --opt= Specify optimization flags [NO_MESON]
104: (2) --arch= Specify architecture specific optimization flags
[NO_MESON]
105: (2) --noopt Compile without optimization [NO_MESON]
106: (2) --noarch Compile without arch-dependent optimization [NO_MESON]
107: (2) --debug Compile with debugging information
108: (2) --dep <dependency>
109: (23) Specify a meson dependency for the module. This may
110: (23) be passed multiple times for multiple dependencies.
111: (23) Dependencies are stored in a list for further
processing.
112: (23) Example: --dep lapack --dep scalapack
113: (23) This will identify "lapack" and "scalapack" as
dependencies
114: (23) and remove them from argv, leaving a dependencies list
115: (23) containing ["lapack", "scalapack"].
116: (2) --backend <backend_type>
117: (23) Specify the build backend for the compilation process.
118: (23) The supported backends are 'meson' and 'distutils'.
119: (23) If not specified, defaults to 'distutils'. On
120: (23) Python 3.12 or higher, the default is 'meson'.
121: (0) Extra options (only effective with -c):
122: (2) --link-<resource> Link extension module with <resource> as defined
123: (23) by numpy.distutils/system_info.py. E.g. to link
124: (23) with optimized LAPACK libraries (veclib on MacOSX,
125: (23) ATLAS elsewhere), use --link-lapack_opt.
126: (23) See also --help-link switch. [NO_MESON]
127: (2) -L/path/to/lib/ -l<libname>
128: (2) -D<define> -U<name>
129: (2) -I/path/to/include/
130: (2) <filename>.o <filename>.so <filename>.a
131: (2) Using the following macros may be required with non-gcc Fortran

compilers:
    -DPREPEND_FORTRAN -DNO_APPEND_FORTRAN -DUPPERCASE_FORTRAN
    -DUNDERSCORE_G77
When using -DF2PY_REPORT_ATEXIT, a performance report of F2PY
interface is printed out at exit (platforms: Linux).
When using -DF2PY_REPORT_ON_ARRAY_COPY=<int>, a message is
sent to stderr whenever F2PY interface makes a copy of an
array. Integer <int> sets the threshold for array sizes when
a message should be shown.

## File 157 - \_src\_pyf.py:

```

1: (0)           import re
2: (0)           """
3: (0)           process_file(filename)
4: (2)             takes templated file .xxx.src and produces .xxx file where .xxx
5: (2)             is .pyf .f90 or .f using the following template rules:
6: (2)             '<..>' denotes a template.
7: (2)             All function and subroutine blocks in a source file with names that
8: (2)             contain '<..>' will be replicated according to the rules in '<..>'.
9: (2)             The number of comma-separated words in '<..>' will determine the number of
10: (2)            replicates.
11: (2)             '<..>' may have two different forms, named and short. For example,
12: (2)            named:
13: (3)               <p=d,s,z,c> where anywhere inside a block '<p>' will be replaced with
14: (3)                 'd', 's', 'z', and 'c' for each replicate of the block.
15: (3)               <_c> is already defined: <_c=s,d,c,z>
16: (3)               <_t> is already defined: <_t=real,double precision,complex,double complex>
17: (2)            short:
18: (3)               <s,d,c,z>, a short form of the named, useful when no <p> appears inside
19: (3)                 a block.
20: (2)             In general, '<..>' contains a comma separated list of arbitrary
21: (2)             expressions. If these expression must contain a comma|leftarrow|rightarrow, then prepend the comma|leftarrow|rightarrow with a backslash.
22: (2)             If an expression matches '\<index>' then it will be replaced
23: (2)               by <index>-th expression.
24: (2)             Note that all '<..>' forms in a block must have the same number of
25: (2)               comma-separated entries.
26: (2)             Predefined named template rules:
27: (1)               <prefix=s,d,c,z>
28: (2)               <ftype=real,double precision,complex,double complex>
29: (2)               <ftypereal=real,double precision,\0,\1>
30: (2)               <cctype=float,double,complex_float,complex_double>
31: (2)               <cctypereal=float,double,\0,\1>

117: (4)                     Notes
118: (4)                     -----
119: (4)                     .. versionadded:: 1.21.1
120: (4)                     Unless the build system you are using has specific support for f2py,
121: (4)                     building a Python extension using a ``.pyf`` signature file is a two-step
122: (4)                     process. For a module ``mymod``:
123: (6)                         * Step 1: run ``python -m numpy.f2py mymod.pyf --quiet``. This
123: (6)                             generates ``_mymodmodule.c`` and (if needed)

```

```

124: (6)          ``_fblas-f2pywrappers.f`` files next to ``mymod.pyf``.
125: (4)          * Step 2: build your Python extension module. This requires the
126: (6)          following source files:
127: (6)          * ``_mymodmodule.c``
128: (6)          * ``_mymod-f2pywrappers.f`` (if it was generated in Step 1)
129: (6)          * ``fortranobject.c``
130: (4)          See Also

116: (4)                 """This test suite tests various expressions that are used as dimension
117: (4)                 specifications.
118: (4)                 There exists two usage cases where analyzing dimensions
119: (4)                 specifications are important.
120: (4)                 In the first case, the size of output arrays must be defined based
121: (4)                 on the inputs to a Fortran function. Because Fortran supports
122: (4)                 arbitrary bases for indexing, for instance, `arr(lower:upper)`
123: (4)                 f2py has to evaluate an expression `upper - lower + 1` where
124: (4)                 `lower` and `upper` are arbitrary expressions of input parameters.
125: (4)                 The evaluation is performed in C, so f2py has to translate Fortran
126: (4)                 expressions to valid C expressions (an alternative approach is
127: (4)                 that a developer specifies the corresponding C expressions in a
128: (4)                 .pyf file).
129: (4)                 In the second case, when user provides an input array with a given
130: (4)                 size but some hidden parameters used in dimensions specifications
131: (4)                 need to be determined based on the input array size. This is a
132: (4)                 harder problem because f2py has to solve the inverse problem: find
133: (4)                 a parameter `p` such that `upper(p) - lower(p) + 1` equals to the
134: (4)                 size of input array. In the case when this equation cannot be
135: (4)                 solved (e.g. because the input array size is wrong), raise an
136: (4)                 error before calling the Fortran function (that otherwise would
137: (4)                 likely crash Python process when the size of input arrays is
138: (4)                 wrong). f2py currently supports this case only when the equation
139: (4)                 is linear with respect to unknown parameter.
140: (4)                 """

153: (12)                            1.14423775e-17+1.14423775e-17j,  0.00000000e+00+1.22464680e-16j])
154: (4)                             In this example, real input has an FFT which is Hermitian, i.e., symmetric
155: (4)                             in the real part and anti-symmetric in the imaginary part, as described in
156: (4)                             the `numpy.fft` documentation:
157: (4)                             >>> import matplotlib.pyplot as plt
158: (4)                             >>> t = np.arange(256)
159: (4)                             >>> sp = np.fft.fft(np.sin(t))
160: (4)                             >>> freq = np.fft.fftfreq(t.shape[-1])
161: (4)                             >>> plt.plot(freq, sp.real, freq, sp.imag)
162: (4)                             [<matplotlib.lines.Line2D object at 0x...>, <matplotlib.lines.Line2D
object at 0x...>]
163: (4)                             >>> plt.show()
164: (4)                             """
165: (4)                             a = asarray(a)

```

```

166: (4)           if n is None:
167: (8)             n = a.shape[axis]
168: (4)             inv_norm = _get_forward_norm(n, norm)
169: (4)             output = _raw_fft(a, n, axis, False, True, inv_norm)
170: (4)             return output
171: (0) @array_function_dispatch(_fft_dispatcher)
172: (0) def ifft(a, n=None, axis=-1, norm=None):
173: (4)     """
174: (4)         Compute the one-dimensional inverse discrete Fourier Transform.
175: (4)         This function computes the inverse of the one-dimensional *n*-point
176: (4)         discrete Fourier transform computed by `fft`. In other words,
177: (4)         ``ifft(fft(a)) == a`` to within numerical accuracy.
178: (4)         For a general description of the algorithm and definitions,
179: (4)         see `numpy.fft`.
180: (4)         The input should be ordered in the same way as is returned by `fft`,
181: (4)         i.e.,
182: (4)         * ``a[0]`` should contain the zero frequency term,
183: (4)         * ``a[1:n//2]`` should contain the positive-frequency terms,
184: (4)         * ``a[n//2 + 1:]`` should contain the negative-frequency terms, in
185: (6)         increasing order starting from the most negative frequency.
186: (4)         For an even number of input points, ``A[n//2]`` represents the sum of
187: (4)         the values at the positive and negative Nyquist frequencies, as the two
188: (4)         are aliased together. See `numpy.fft` for details.
189: (4)     Parameters
190: (4)     -----
191: (4)     a : array_like
192: (8)       Input array, can be complex.
193: (4)     n : int, optional
194: (8)       Length of the transformed axis of the output.
195: (8)       If `n` is smaller than the length of the input, the input is cropped.
196: (8)       If it is larger, the input is padded with zeros. If `n` is not given,
197: (8)       the length of the input along the axis specified by `axis` is used.
198: (8)       See notes about padding issues.
199: (4)     axis : int, optional
200: (8)       Axis over which to compute the inverse DFT. If not given, the last
201: (8)       axis is used.
202: (4)     norm : {"backward", "ortho", "forward"}, optional
203: (8)       .. versionadded:: 1.10.0
204: (8)       Normalization mode (see `numpy.fft`). Default is "backward".
205: (8)       Indicates which direction of the forward/backward pair of transforms
206: (8)       is scaled and with what normalization factor.
207: (8)       .. versionadded:: 1.20.0
208: (12)      The "backward", "forward" values were added.
209: (4)     Returns
210: (4)     -----
211: (4)     out : complex ndarray
212: (8)       The truncated or zero-padded input, transformed along the axis
213: (8)       indicated by `axis`, or the last one if `axis` is not specified.
214: (4)     Raises
215: (4)     -----
216: (4)     IndexError
217: (8)       If `axis` is not a valid axis of `a`.
218: (4)     See Also
219: (4)     -----
220: (4)     numpy.fft : An introduction, with definitions and general explanations.
221: (4)     fft : The one-dimensional (forward) FFT, of which `ifft` is the inverse
222: (4)     ifft2 : The two-dimensional inverse FFT.
223: (4)     ifftn : The n-dimensional inverse FFT.
224: (4)     Notes
225: (4)     -----
226: (4)     If the input parameter `n` is larger than the size of the input, the input
227: (4)     is padded by appending zeros at the end. Even though this is the common
228: (4)     approach, it might lead to surprising results. If a different padding is
229: (4)     desired, it must be performed before calling `ifft`.
230: (4)     Examples
231: (4)     -----
232: (4)     >>> np.fft.ifft([0, 4, 0, 0])
233: (4)     array([ 1.+0.j,  0.+1.j, -1.+0.j,  0.-1.j]) # may vary
234: (4)     Create and plot a band-limited signal with random phases:

```

```

235: (4)          >>> import matplotlib.pyplot as plt
236: (4)          >>> t = np.arange(400)
237: (4)          >>> n = np.zeros((400,), dtype=complex)
238: (4)          >>> n[40:60] = np.exp(1j*np.random.uniform(0, 2*np.pi, (20,)))
239: (4)          >>> s = np.fft.ifft(n)
240: (4)          >>> plt.plot(t, s.real, label='real')
241: (4)          [<matplotlib.lines.Line2D object at ...>]
242: (4)          >>> plt.plot(t, s.imag, '--', label='imaginary')
243: (4)          [<matplotlib.lines.Line2D object at ...>]
244: (4)          >>> plt.legend()
245: (4)          <matplotlib.legend.Legend object at ...>
246: (4)          >>> plt.show()
247: (4)          """
248: (4)          a = asarray(a)
249: (4)          if n is None:

283: (8)              The truncated or zero-padded input, transformed along the axis
284: (8)              indicated by `axis`, or the last one if `axis` is not specified.
285: (8)              If `n` is even, the length of the transformed axis is `` $(n/2)+1$ ``.
286: (8)              If `n` is odd, the length is `` $(n+1)/2$ ``.
287: (4)          Raises
288: (4)          -----
289: (4)          IndexError
290: (8)              If `axis` is not a valid axis of `a`.
291: (4)          See Also
292: (4)          -----
293: (4)          numpy.fft : For definition of the DFT and conventions used.
294: (4)          irfft : The inverse of `rfft`.
295: (4)          fft : The one-dimensional FFT of general (complex) input.
296: (4)          fftn : The *n*-dimensional FFT.
297: (4)          rfftn : The *n*-dimensional FFT of real input.
298: (4)          Notes
299: (4)          -----
300: (4)          When the DFT is computed for purely real input, the output is
301: (4)          Hermitian-symmetric, i.e. the negative frequency terms are just the
complex
302: (4)          conjugates of the corresponding positive-frequency terms, and the

```

```

303: (4) negative-frequency terms are therefore redundant. This function does not
304: (4) compute the negative frequency terms, and the length of the transformed
305: (4) axis of the output is therefore ``n//2 + 1``.
306: (4) When ``A = rfft(a)`` and fs is the sampling frequency, ``A[0]`` contains
307: (4) the zero-frequency term  $0*fs$ , which is real due to Hermitian symmetry.
308: (4) If `n` is even, ``A[-1]`` contains the term representing both positive
309: (4) and negative Nyquist frequency ( $+fs/2$  and  $-fs/2$ ), and must also be purely
310: (4) real. If `n` is odd, there is no term at  $fs/2$ ; ``A[-1]`` contains
311: (4) the largest positive frequency ( $fs/2*(n-1)/n$ ), and is complex in the
312: (4) general case.
313: (4) If the input `a` contains an imaginary part, it is silently discarded.
314: (4) Examples
315: (4) -----
316: (4) >>> np.fft.fft([0, 1, 0, 0])
317: (4) array([ 1.+0.j, 0.-1.j, -1.+0.j, 0.+1.j]) # may vary
318: (4) >>> np.fft.rfft([0, 1, 0, 0])
319: (4) array([ 1.+0.j, 0.-1.j, -1.+0.j]) # may vary
320: (4) Notice how the final element of the `fft` output is the complex conjugate
321: (4) of the second element, for real input. For `rfft`, this symmetry is
322: (4) exploited to compute only the non-negative frequency terms.
323: (4) """
324: (4) a = asarray(a)
325: (4) if n is None:
326: (8)     n = a.shape[axis]
327: (4)     inv_norm = _get_forward_norm(n, norm)
328: (4)     output = _raw_fft(a, n, axis, True, True, inv_norm)
329: (4)     return output
330: (0) @array_function_dispatch(_fft_dispatcher)
331: (0) def irfft(a, n=None, axis=-1, norm=None):
332: (4) """
333: (4)     Computes the inverse of `rfft`.
334: (4)     This function computes the inverse of the one-dimensional *n*-point
335: (4)     discrete Fourier Transform of real input computed by `rfft`.
336: (4)     In other words, ``irfft(rfft(a), len(a)) == a`` to within numerical
337: (4)     accuracy. (See Notes below for why ``len(a)`` is necessary here.)
338: (4)     The input is expected to be in the form returned by `rfft`, i.e. the
339: (4)     real zero-frequency term followed by the complex positive frequency terms
340: (4)     in order of increasing frequency. Since the discrete Fourier Transform of
341: (4)     real input is Hermitian-symmetric, the negative frequency terms are taken
342: (4)     to be the complex conjugates of the corresponding positive frequency
terms.
343: (4) Parameters
344: (4) -----
345: (4) a : array_like
346: (8)     The input array.
347: (4) n : int, optional
348: (8)     Length of the transformed axis of the output.
349: (8)     For `n` output points, ``n//2+1`` input points are necessary. If the
350: (8)     input is longer than this, it is cropped. If it is shorter than this,
351: (8)     it is padded with zeros. If `n` is not given, it is taken to be
352: (8)     ``2*(m-1)`` where ``m`` is the length of the input along the axis
353: (8)     specified by `axis`.
354: (4) axis : int, optional
355: (8)     Axis over which to compute the inverse FFT. If not given, the last
356: (8)     axis is used.
357: (4) norm : {"backward", "ortho", "forward"}, optional
358: (8)     .. versionadded:: 1.10.0
359: (8)     Normalization mode (see `numpy.fft`). Default is "backward".
360: (8)     Indicates which direction of the forward/backward pair of transforms
361: (8)     is scaled and with what normalization factor.
362: (8)     .. versionadded:: 1.20.0
363: (12)     The "backward", "forward" values were added.
364: (4) Returns
365: (4) -----
366: (4) out : ndarray
367: (8)     The truncated or zero-padded input, transformed along the axis
368: (8)     indicated by `axis`, or the last one if `axis` is not specified.
369: (8)     The length of the transformed axis is `n`, or, if `n` is not given,
370: (8)     ``2*(m-1)`` where ``m`` is the length of the transformed axis of the

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

371: (8)           input. To get an odd number of output points, `n` must be specified.
372: (4)           Raises
373: (4)           -----
374: (4)           IndexError
375: (8)           If `axis` is not a valid axis of `a`.
376: (4)           See Also
377: (4)           -----
378: (4)           numpy.fft : For definition of the DFT and conventions used.
379: (4)           rfft : The one-dimensional FFT of real input, of which `irfft` is inverse.
380: (4)           fft : The one-dimensional FFT.
381: (4)           irfft2 : The inverse of the two-dimensional FFT of real input.
382: (4)           irfftn : The inverse of the *n*-dimensional FFT of real input.
383: (4)           Notes
384: (4)           -----
385: (4)           Returns the real valued `n`-point inverse discrete Fourier transform
386: (4)           of `a`, where `a` contains the non-negative frequency terms of a
387: (4)           Hermitian-symmetric sequence. `n` is the length of the result, not the
388: (4)           input.
389: (4)           If you specify an `n` such that `a` must be zero-padded or truncated, the
390: (4)           extra/removed values will be added/removed at high frequencies. One can
391: (4)           thus resample a series to `m` points via Fourier interpolation by:
392: (4)           ``a_resamp = irfft(rfft(a), m)``.
393: (4)           The correct interpretation of the hermitian input depends on the length of
394: (4)           the original data, as given by `n`. This is because each input shape could
395: (4)           correspond to either an odd or even length signal. By default, `irfft`
396: (4)           assumes an even output length which puts the last entry at the Nyquist
397: (4)           frequency; aliasing with its symmetric counterpart. By Hermitian symmetry,
398: (4)           the value is thus treated as purely real. To avoid losing information, the
399: (4)           correct length of the real input **must** be given.
400: (4)           Examples
401: (4)           -----
402: (4)           >>> np.fft.ifft([1, -1j, -1, 1j])
403: (4)           array([0.+0.j, 1.+0.j, 0.+0.j, 0.+0.j]) # may vary
404: (4)           >>> np.fft.irfft([1, -1j, -1])
405: (4)           array([0., 1., 0., 0.])
406: (4)           Notice how the last term in the input to the ordinary `ifft` is the
407: (4)           complex conjugate of the second term, and the output has zero imaginary
408: (4)           part everywhere. When calling `irfft`, the negative frequencies are not
409: (4)           specified, and the output array is purely real.
410: (4)           """
411: (4)           a = asarray(a)
412: (4)           if n is None:

424: (4)               a : array_like
425: (8)                   The input array.
426: (4)               n : int, optional
427: (8)                   Length of the transformed axis of the output. For `n` output
428: (8)                   points, ``n//2 + 1`` input points are necessary. If the input is
429: (8)                   longer than this, it is cropped. If it is shorter than this, it is
430: (8)                   padded with zeros. If `n` is not given, it is taken to be ``2*(m-1)``
431: (8)                   where ``m`` is the length of the input along the axis specified by
432: (8)                   `axis`.
433: (4)               axis : int, optional
434: (8)                   Axis over which to compute the FFT. If not given, the last
435: (8)                   axis is used.
436: (4)               norm : {"backward", "ortho", "forward"}, optional
437: (8)                   .. versionadded:: 1.10.0
438: (8)                   Normalization mode (see `numpy.fft`). Default is "backward".
439: (8)                   Indicates which direction of the forward/backward pair of transforms

```

```

440: (8)           is scaled and with what normalization factor.
441: (8)           .. versionadded:: 1.20.0
442: (12)          The "backward", "forward" values were added.
443: (4)          Returns
444: (4)
445: (4)          out : ndarray
446: (8)          The truncated or zero-padded input, transformed along the axis
447: (8)          indicated by `axis`, or the last one if `axis` is not specified.
448: (8)          The length of the transformed axis is `n`, or, if `n` is not given,
449: (8)          ``2*m - 2`` where ``m`` is the length of the transformed axis of
450: (8)          the input. To get an odd number of output points, `n` must be
451: (8)          specified, for instance as ``2*m - 1`` in the typical case,
452: (4)          Raises
453: (4)
454: (4)          IndexError
455: (8)          If `axis` is not a valid axis of `a`.
456: (4)          See also
457: (4)
458: (4)          rfft : Compute the one-dimensional FFT for real input.
459: (4)          ihfft : The inverse of `hfft`.
460: (4)          Notes
461: (4)
462: (4)          `hfft`/`ihfft` are a pair analogous to `rfft`/`irfft`, but for the
463: (4)          opposite case: here the signal has Hermitian symmetry in the time
464: (4)          domain and is real in the frequency domain. So here it's `hfft` for
465: (4)          which you must supply the length of the result if it is to be odd.
466: (4)          * even: ``ihfft(hfft(a, 2*len(a) - 2)) == a``, within roundoff error,
467: (4)          * odd: ``ihfft(hfft(a, 2*len(a) - 1)) == a``, within roundoff error.
468: (4)          The correct interpretation of the hermitian input depends on the length of
469: (4)          the original data, as given by `n`. This is because each input shape could
470: (4)          correspond to either an odd or even length signal. By default, `hfft`
471: (4)          assumes an even output length which puts the last entry at the Nyquist
472: (4)          frequency; aliasing with its symmetric counterpart. By Hermitian symmetry,
473: (4)          the value is thus treated as purely real. To avoid losing information, the
474: (4)          shape of the full signal **must** be given.
475: (4)          Examples
476: (4)
477: (4)          >>> signal = np.array([1, 2, 3, 4, 3, 2])
478: (4)          >>> np.fft.fft(signal)

                           ...                                2 * np.pi * np.arange(200) / 34)
    >>> S = np.sin(X) + np.cos(Y) + np.random.uniform(0, 1, X.shape)
    >>> FS = np.fft.fftn(S)
    >>> plt.imshow(np.log(np.abs(np.fft.fftshift(FS))**2))
    <matplotlib.image.AxesImage object at 0x...>
    >>> plt.show()
    """
    return _raw_fftn(a, s, axes, fft, norm)
@array_function_dispatch(_fftn_dispatcher)
def ifftn(a, s=None, axes=None, norm=None):
    """
    Compute the N-dimensional inverse discrete Fourier Transform.
    This function computes the inverse of the N-dimensional discrete
    Fourier Transform over any number of axes in an M-dimensional array by
    means of the Fast Fourier Transform (FFT). In other words,
    ``ifftn(fftn(a)) == a`` to within numerical accuracy.
    For a description of the definitions and conventions used, see
    `numpy.fft`.

    The input, analogously to `ifft`, should be ordered in the same way as is
    returned by `fftn`, i.e. it should have the term for zero frequency
    in all axes in the low-order corner, the positive frequency terms in the
    first half of all axes, the term for the Nyquist frequency in the middle
    of all axes and the negative frequency terms in the second half of all
    axes, in order of decreasingly negative frequency.

    Parameters
    -----
    a : array_like
        Input array, can be complex.
    s : sequence of ints, optional
        Shape (length of each transformed axis) of the output
        (``s[0]`` refers to axis 0, ``s[1]`` to axis 1, etc.).
        This corresponds to ``n`` for ``ifft(x, n)``.
        Along any axis, if the given shape is smaller than that of the input,
        the input is cropped. If it is larger, the input is padded with
        zeros.
    axes : sequence of ints, optional
        Axes over which to compute the IFFT. If not given, the last
        axes are used, or all axes if `s` is also not specified.
        Repeated indices in `axes` means that the inverse transform over that
        axis is performed multiple times.
    norm : {"backward", "ortho", "forward"}, optional
        .. versionadded:: 1.10.0
        Normalization mode (see `numpy.fft`). Default is "backward".
        Indicates which direction of the forward/backward pair of transforms
        is scaled and with what normalization factor.
        .. versionadded:: 1.20.0
        The "backward", "forward" values were added.

    Returns
    -----

```

915: (4)      Compute the N-dimensional discrete Fourier Transform for real input.
916: (4)      This function computes the N-dimensional discrete Fourier Transform over
917: (4)      any number of axes in an M-dimensional real array by means of the Fast
918: (4)      Fourier Transform (FFT). By default, all axes are transformed, with the
919: (4)      real transform performed over the last axis, while the remaining
920: (4)      transforms are complex.
921: (4)
922: (4)      Parameters
923: (8)      -----
924: (4)      a : array_like
925: (8)          Input array, taken to be real.
926: (8)      s : sequence of ints, optional
927: (8)          Shape (length along each transformed axis) to use from the input.
928: (8)          (`s[0]` refers to axis 0, `s[1]` to axis 1, etc.).
929: (8)          The final element of `s` corresponds to `n` for ``rfft(x, n)``,
930: (8)          while for the remaining axes, it corresponds to `n` for ``fft(x, n)``.
931: (8)          Along any axis, if the given shape is smaller than that of the input,
932: (8)          the input is cropped. If it is larger, the input is padded with
933: (4)          zeros.
934: (8)      if `s` is not given, the shape of the input along the axes specified
935: (8)          by `axes` is used.
936: (4)      axes : sequence of ints, optional
937: (8)          Axes over which to compute the FFT. If not given, the last ``len(s)``
938: (8)          axes are used, or all axes if `s` is also not specified.
939: (8)      norm : {"backward", "ortho", "forward"}, optional
940: (8)          .. versionadded:: 1.10.0
941: (8)          Normalization mode (see `numpy.fft`). Default is "backward".
942: (12)          Indicates which direction of the forward/backward pair of transforms
943: (4)          is scaled and with what normalization factor.
944: (4)          .. versionadded:: 1.20.0
945: (4)          The "backward", "forward" values were added.
946: (4)      Returns
947: (4)      -----
948: (4)      out : complex ndarray
949: (8)          The truncated or zero-padded input, transformed along the axes
950: (8)          indicated by `axes`, or by a combination of `s` and `a`,
951: (8)          as explained in the parameters section above.
952: (8)          The length of the last axis transformed will be ``s[-1]//2+1```,
953: (8)          while the remaining transformed axes will have lengths according to
954: (8)          `s`, or unchanged from the input.
955: (4)      Raises
956: (4)      -----
957: (4)      ValueError
958: (8)          If `s` and `axes` have different length.
959: (4)      IndexError
960: (8)          If an element of `axes` is larger than than the number of axes of `a`.
961: (4)      See Also
962: (4)      -----
963: (4)      irfftn : The inverse of `rfftn`, i.e. the inverse of the n-dimensional FFT
964: (4)          of real input.
965: (4)      fft : The one-dimensional FFT, with definitions and conventions used.
966: (4)      rfft : The one-dimensional FFT of real input.
967: (4)      fftn : The n-dimensional FFT.
968: (4)      rfft2 : The two-dimensional FFT of real input.
969: (4)      Notes
970: (4)      -----
971: (4)      The transform for real input is performed over the last transformation
972: (4)          axis, as by `rfft`, then the transform over the remaining axes is
973: (4)          performed as by `fftn`. The order of the output is as for `rfft` for the
974: (4)          final transformation axis, and as for `fftn` for the remaining
975: (4)          transformation axes.
976: (4)      See `fft` for details, definitions and conventions used.
977: (4)      Examples
978: (4)      -----
979: (12)      >>> a = np.ones((2, 2, 2))
980: (11)      >>> np.fft.rfftn(a)

```

```

981: (12)           [0.+0.j,  0.+0.j]]])

1116: (4)

      -----
      a : array_like
          Input array.
      s : sequence of ints, optional
          Shape (length of each transformed axis) of the output
          (` `s[0]` ` refers to axis 0, ``s[1]`` to axis 1, etc.). ` `s` is also the
          number of input points used along this axis, except for the last axis,
          where ``s[-1]//2+1`` points of the input are used.
          Along any axis, if the shape indicated by ` `s` is smaller than that of
          the input, the input is cropped. If it is larger, the input is padded
          with zeros. If ` `s` is not given, the shape of the input along the axes
          specified by axes is used. Except for the last axis which is taken to
          be ``2*(m-1)`` where ``m`` is the length of the input along that axis.
      axes : sequence of ints, optional
          Axes over which to compute the inverse FFT. If not given, the last
          ` `len(s)` ` axes are used, or all axes if ` `s` is also not specified.
          Repeated indices in ` `axes` means that the inverse transform over that
          axis is performed multiple times.
      norm : {"backward", "ortho", "forward"}, optional
          .. versionadded:: 1.10.0
          Normalization mode (see ` `numpy.fft` ). Default is "backward".
          Indicates which direction of the forward/backward pair of transforms
          is scaled and with what normalization factor.
          .. versionadded:: 1.20.0
              The "backward", "forward" values were added.

      Returns
      -----
      out : ndarray
          The truncated or zero-padded input, transformed along the axes
          indicated by ` `axes` , or by a combination of ` `s` or ` `a` ,
          as explained in the parameters section above.
          The length of each transformed axis is as given by the corresponding
          element of ` `s` , or the length of the input in every axis except for
          last one if ` `s` is not given. In the final transformed axis the
          of the output when ` `s` is not given is ``2*(m-1)`` where ``m`` is the
          length of the final transformed axis of the input. To get an odd
          number of output points in the final axis, ` `s` must be specified.

      Raises
      -----
      ValueError
          If ` `s` and ` `axes` have different length.
      IndexError
          If an element of ` `axes` is larger than than the number of axes of ` `a` .
      See Also
      -----
      rfftn : The forward n-dimensional FFT of real input,
              of which ` `ifftn` is the inverse.
      fft : The one-dimensional FFT, with definitions and conventions used.
      irfft : The inverse of the one-dimensional FFT of real input.
      irfft2 : The inverse of the two-dimensional FFT of real input.

      Notes
      -----
      See ` `fft` for definitions and conventions used.
      See ` `rfft` for definitions and conventions used for real input.
      The correct interpretation of the hermitian input depends on the shape of
      the original data, as given by ` `s` . This is because each input shape could
      correspond to either an odd or even length signal. By default, ` `irfftn`'
      assumes an even output length which puts the last entry at the Nyquist
      frequency; aliasing with its symmetric counterpart. When performing the
      final complex to real transform, the last value is thus treated as purely
      real. To avoid losing information, the correct shape of the real input
      **must** be given.

      Examples
      -----
      >>> a = np.zeros((3, 2, 2))
      >>> a[0, 0, 0] = 3 * 2 * 2
      >>> np.fft.irfftn(a)

41: (0) Background information
42: (0)
43: (0) Fourier analysis is fundamentally a method for expressing a function as a
44: (0) sum of periodic components, and for recovering the function from those
45: (0) components. When both the function and its Fourier transform are
46: (0) replaced with discretized counterparts, it is called the discrete Fourier
47: (0) transform (DFT). The DFT has become a mainstay of numerical computing in
48: (0) part because of a very fast algorithm for computing it, called the Fast
49: (0) Fourier Transform (FFT), which was known to Gauss (1805) and was brought
50: (0) to light in its current form by Cooley and Tukey [CT]_. Press et al. [NR]_
51: (0) provide an accessible introduction to Fourier analysis and its
52: (0) applications.
53: (0) Because the discrete Fourier transform separates its input into
54: (0) components that contribute at discrete frequencies, it has a great number
55: (0) of applications in digital signal processing, e.g., for filtering, and in
56: (0) this context the discretized input to the transform is customarily
57: (0) referred to as a *signal*, which exists in the *time domain*. The output
58: (0) is called a *spectrum* or *transform* and exists in the *frequency
59: (0) domain*.
60: (0) Implementation details
61: (0)
62: (0) There are many ways to define the DFT, varying in the sign of the
63: (0) exponent, normalization, etc. In this implementation, the DFT is defined
64: (0) as
65: (0) .. math::
66: (3)   A_k = \sum_{m=0}^{n-1} a_m \exp\left(-2\pi i \frac{mk}{n}\right)
67: (3)   \quad k = 0, \dots, n-1.
68: (0) The DFT is in general defined for complex inputs and outputs, and a
69: (0) single-frequency component at linear frequency :math:`f` is
70: (0) represented by a complex exponential
71: (0) :math:`a_m = \exp\left(2\pi i f m \Delta t\right)`, where :math:`\Delta t`_
72: (0) is the sampling interval.
73: (0) The values in the result follow so-called "standard" order: If ``A =

fft(a, n)``, then ``A[0]`` contains the zero-frequency term (the sum of the signal), which is always purely real for real inputs. Then ``A[1:n/2]`` contains the positive-frequency terms, and ``A[n/2+1:]`` contains the negative-frequency terms, in order of decreasingly negative frequency. For an even number of input points, ``A[n/2]`` represents both positive and negative Nyquist frequency, and is also purely real for real input. For an odd number of input points, ``A[(n-1)/2]`` contains the largest positive frequency, while ``A[(n+1)/2]`` contains the largest negative frequency. The routine ``np.fft.freq(n)`` returns an array giving the frequencies of corresponding elements in the output. The routine ``np.fft.fftshift(A)`` shifts transforms and their frequencies to put the zero-frequency components in the middle, and ``np.fft.ifftshift(A)`` undoes that shift.

When the input `a` is a time-domain signal and ``A = fft(a)``, ``np.abs(A)`` is its amplitude spectrum and ``np.abs(A)\*\*2`` is its power spectrum. The phase spectrum is obtained by ``np.angle(A)``.

The inverse DFT is defined as

```
.. math::  

    a_m = \frac{1}{n} \sum_{k=0}^{n-1} A_k \exp(-j \frac{2\pi}{n} k m)
```

It differs from the forward transform by the sign of the exponential argument and the default normalization by :math:`1/n`.

Type Promotion

-----

numpy.fft` promotes ``float32`` and ``complex64`` arrays to ``float64`` and ``complex128`` arrays respectively. For an FFT implementation that does not promote input arrays, see `scipy.fftpack`.

Normalization

-----

The argument ``norm`` indicates which direction of the pair of direct/inverse transforms is scaled and with what normalization factor.

The default normalization (``"backward"``) has the direct (forward) transforms unscaled and the inverse (backward) transforms scaled by :math:`1/n`. It is possible to obtain unitary transforms by setting the keyword argument ``norm`` to ``"ortho"`` so that both direct and inverse transforms are scaled by :math:`1/\sqrt{n}`. Finally, setting the keyword argument ``norm`` to ``"forward"`` has the direct transforms scaled by :math:`1/n` and the inverse transforms unscaled (i.e. exactly opposite to the default ``"backward"``). ``None`` is an alias of the default option ``"backward"`` for backward compatibility.

Real and Hermitian transforms

-----

When the input is purely real, its transform is Hermitian, i.e., the component at frequency :math:f\_k` is the complex conjugate of the component at frequency :math:-f\_k`, which means that for real inputs there is no information in the negative frequency components that is not already available from the positive frequency components.

The family of `rfft` functions is designed to operate on real inputs, and exploits this symmetry by computing only the positive frequency components, up to and including the Nyquist frequency. Thus, ``n`` input points produce ``n/2+1`` complex output points. The inverses of this family assumes the same symmetry of its input, and for an output of ``n`` points uses ``n/2+1`` input points. Correspondingly, when the spectrum is purely real, the signal is Hermitian. The `hfft` family of functions exploits this symmetry by using ``n/2+1`` complex points in the input (time) domain for ``n`` real points in the frequency domain.

In higher dimensions, FFTs are used, e.g., for image analysis and filtering. The computational efficiency of the FFT means that it can also be a faster way to compute large convolutions, using the property that a convolution in the time domain is equivalent to a point-by-point multiplication in the frequency domain.

Higher dimensions

-----

In two dimensions, the DFT is defined as

```
.. math::  

    A_{kl} = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} a_{mn} \exp(-j \frac{2\pi}{M} k m + j \frac{2\pi}{N} l n)
```

```

N}\right)\right\}
142: (3)          \quad\quad k = 0, \ldots, M-1;\quad l = 0, \ldots, N-1,
143: (0)          which extends in the obvious way to higher dimensions, and the inverses
144: (0)          in higher dimensions also extend in the same way.

`@array_function_dispatch(_pad_dispatcher, module='numpy')`

`def pad(array, pad_width, mode='constant', **kwargs):`

`"""`

Pad an array.

Parameters

-----

array : array\_like of rank N

The array to pad.

pad\_width : {sequence, array\_like, int}

Number of values padded to the edges of each axis.

`((before\_1, after\_1), ... (before\_N, after\_N))` unique pad widths for each axis.

`((before, after)` or `((before, after),)` yields same before and after pad for each axis.

`((pad,)` or `int` is a shortcut for before = after = pad width for all axes.

mode : str or function, optional

One of the following string values or a user supplied function.

'constant' (default)

Pads with a constant value.

'edge'

Pads with the edge values of array.

'linear\_ramp'

Pads with the linear ramp between end\_value and the array edge value.

'maximum'

Pads with the maximum value of all or part of the vector along each axis.

'mean'

Pads with the mean value of all or part of the vector along each axis.

'median'

Pads with the median value of all or part of the vector along each axis.

'minimum'

Pads with the minimum value of all or part of the vector along each axis.

'reflect'

Pads with the reflection of the vector mirrored on the first and last values of the vector along each axis.

'symmetric'

Pads with the reflection of the vector mirrored along the edge of the array.

'wrap'

Pads with the wrap of the vector along the axis.

The first values are used to pad the end and the end values are used to pad the beginning.

'empty'

Pads with undefined values.

.. versionadded:: 1.17

<function>

Padding function, see Notes.

stat\_length : sequence or int, optional

Used in 'maximum', 'mean', 'median', and 'minimum'. Number of values at edge of each axis used to calculate the statistic value.

`((before\_1, after\_1), ... (before\_N, after\_N))` unique statistic lengths for each axis.

`((before, after)` or `((before, after),)` yields same before and after statistic lengths for each axis.

`((stat\_length,)` or `int` is a shortcut for `before = after = statistic` length for all axes.

Default is `None`, to use the entire axis.

constant\_values : sequence or scalar, optional

Used in 'constant'. The values to set the padded values for each axis.

`((before\_1, after\_1), ... (before\_N, after\_N))` unique pad for each axis.

```

451: (8) ````(before, after)```` or ````((before, after),)```` yields same before
452: (8) and after constants for each axis.
453: (8) ````(constant,)```` or ````constant```` is a shortcut for
454: (8) ````before = after = constant```` for all axes.
455: (8) Default is 0.
456: (4) end_values : sequence or scalar, optional
457: (8) Used in 'linear_ramp'. The values used for the ending value of the
458: (8) linear_ramp and that will form the edge of the padded array.
459: (8) ````((before_1, after_1), ... (before_N, after_N))```` unique end values
460: (8) for each axis.
461: (8) ````(before, after)```` or ````((before, after),)```` yields same before
462: (8) and after end values for each axis.
463: (8) ````(constant,)```` or ````constant```` is a shortcut for
464: (8) ````before = after = constant```` for all axes.
465: (8) Default is 0.
466: (4) reflect_type : {'even', 'odd'}, optional
467: (8) Used in 'reflect', and 'symmetric'. The 'even' style is the
468: (8) default with an unaltered reflection around the edge value. For
469: (8) the 'odd' style, the extended part of the array is created by
470: (8) subtracting the reflected values from two times the edge value.
471: (4) Returns
472: (4)
473: (4) pad : ndarray
474: (8) Padded array of rank equal to `array` with shape increased
475: (8) according to `pad_width`.
476: (4) Notes
477: (4)
478: (4) .. versionadded:: 1.7.0
479: (4) For an array with rank greater than 1, some of the padding of later
480: (4) axes is calculated from padding of previous axes. This is easiest to
481: (4) think about with a rank 2 array where the corners of the padded array
482: (4) are calculated by using padded values from the first axis.
483: (4) The padding function, if used, should modify a rank 1 array in-place. It
484: (4) has the following signature::
485: (8)     padding_func(vector, iaxis_pad_width, iaxis, kwargs)
486: (4) where
487: (8)     vector : ndarray
488: (12)    A rank 1 array already padded with zeros. Padded values are
489: (12)    vector[:iaxis_pad_width[0]] and vector[-iaxis_pad_width[1]:].
490: (8)     iaxis_pad_width : tuple
491: (12)        A 2-tuple of ints, iaxis_pad_width[0] represents the number of
492: (12)        values padded at the beginning of vector where
493: (12)        iaxis_pad_width[1] represents the number of values padded at
494: (12)        the end of vector.
495: (8)     iaxis : int
496: (12)        The axis currently being calculated.
497: (8)     kwargs : dict
498: (12)        Any keyword arguments the function requires.
499: (4) Examples
500: (4)
501: (4) >>> a = [1, 2, 3, 4, 5]
502: (4) >>> np.pad(a, (2, 3), 'constant', constant_values=(4, 6))
503: (4) array([4, 4, 1, ..., 6, 6, 6])
504: (4) >>> np.pad(a, (2, 3), 'edge')
505: (4) array([1, 1, 1, ..., 5, 5, 5])
506: (4) >>> np.pad(a, (2, 3), 'linear_ramp', end_values=(5, -4))
507: (4) array([ 5,  3,  1,  2,  3,  4,  5,  2, -1, -4])
508: (4) >>> np.pad(a, (2,), 'maximum')
509: (4) array([5, 5, 1, 2, 3, 4, 5, 5, 5])
510: (4) >>> np.pad(a, (2,), 'mean')
511: (4) array([3, 3, 1, 2, 3, 4, 5, 3, 3])
512: (4) >>> np.pad(a, (2,), 'median')
513: (4) array([3, 3, 1, 2, 3, 4, 5, 3, 3])
514: (4) >>> a = [[1, 2], [3, 4]]
515: (4) >>> np.pad(a, ((3, 2), (2, 3)), 'minimum')
516: (4) array([[1, 1, 1, 2, 1, 1, 1],
517: (11)           [1, 1, 1, 2, 1, 1, 1],
518: (11)           [1, 1, 1, 2, 1, 1, 1],
519: (11)           [1, 1, 1, 2, 1, 1, 1],

101: (4)             """
102: (4)             Find the unique elements of an array.
103: (4)             Returns the sorted unique elements of an array. There are three optional
104: (4)             outputs in addition to the unique elements:
105: (4)             * the indices of the input array that give the unique values
106: (4)             * the indices of the unique array that reconstruct the input array
107: (4)             * the number of times each unique value comes up in the input array
108: (4)             Parameters
109: (4)             -----
110: (4)             ar : array_like
111: (8)               Input array. Unless `axis` is specified, this will be flattened if it
112: (8)                 is not already 1-D.
113: (4)             return_index : bool, optional
114: (8)               If True, also return the indices of `ar` (along the specified axis,
115: (8)                 if provided, or in the flattened array) that result in the unique
array.
116: (4)             return_inverse : bool, optional
117: (8)               If True, also return the indices of the unique array (for the
specified
118: (8)                 axis, if provided) that can be used to reconstruct `ar`.
119: (4)             return_counts : bool, optional
120: (8)               If True, also return the number of times each unique item appears
in `ar`.
121: (8)             axis : int or None, optional
122: (4)               The axis to operate on. If None, `ar` will be flattened. If an
integer,
123: (8)                 the subarrays indexed by the given axis will be flattened and treated
124: (8)                   as the elements of a 1-D array with the dimension of the given axis,
125: (8)                   see the notes for more details. Object arrays or structured arrays
126: (8)                   that contain objects are not supported if the `axis` kwarg is used.
The
128: (8)               default is None.
129: (8)               .. versionadded:: 1.13.0
130: (4)             equal_nan : bool, optional
131: (8)               If True, collapses multiple NaN values in the return array into one.
132: (8)               .. versionadded:: 1.24
133: (4)             Returns
134: (4)             -----
135: (4)             unique : ndarray

```

```

136: (8)           The sorted unique values.
137: (4)           unique_indices : ndarray, optional
138: (8)           The indices of the first occurrences of the unique values in the
139: (8)           original array. Only provided if `return_index` is True.
140: (4)           unique_inverse : ndarray, optional
141: (8)           The indices to reconstruct the original array from the
142: (8)           unique array. Only provided if `return_inverse` is True.
143: (4)           unique_counts : ndarray, optional
144: (8)           The number of times each of the unique values comes up in the
145: (8)           original array. Only provided if `return_counts` is True.
146: (8)           .. versionadded:: 1.9.0
147: (4)           See Also
148: (4)           -----
149: (4)           numpy.lib.arraysetops : Module with a number of other functions for
150: (28)          performing set operations on arrays.
151: (4)           repeat : Repeat elements of an array.
152: (4)           Notes
153: (4)           -----
154: (4)           When an axis is specified the subarrays indexed by the axis are sorted.
155: (4)           This is done by making the specified axis the first dimension of the array
156: (4)           (move the axis to the first dimension to keep the order of the other axes)
157: (4)           and then flattening the subarrays in C order. The flattened subarrays are
158: (4)           then viewed as a structured type with each element given a label, with the
159: (4)           effect that we end up with a 1-D array of structured types that can be
160: (4)           treated in the same way as any other 1-D array. The result is that the
161: (4)           flattened subarrays are sorted in lexicographic order starting with the
162: (4)           first element.
163: (4)           .. versionchanged: NumPy 1.21
164: (8)           If nan values are in the input array, a single nan is put
165: (8)           to the end of the sorted unique values.
166: (8)           Also for complex arrays all NaN values are considered equivalent
167: (8)           (no matter whether the NaN is in the real or imaginary part).
168: (8)           As the representant for the returned array the smallest one in the
169: (8)           lexicographical order is chosen - see np.sort for how the
lexicographical
170: (8)           order is defined for complex arrays.
171: (4)           Examples
172: (4)           -----
173: (4)           >>> np.unique([1, 1, 2, 2, 3, 3])
174: (4)           array([1, 2, 3])
175: (4)           >>> a = np.array([[1, 1], [2, 3]])
176: (4)           >>> np.unique(a)
177: (4)           array([1, 2, 3])
178: (4)           Return the unique rows of a 2D array
179: (4)           >>> a = np.array([[1, 0, 0], [1, 0, 0], [2, 3, 4]])
180: (4)           >>> np.unique(a, axis=0)
181: (4)           array([[1, 0, 0], [2, 3, 4]])
182: (4)           Return the indices of the original array that give the unique values:
183: (4)           >>> a = np.array(['a', 'b', 'b', 'c', 'a'])
184: (4)           >>> u, indices = np.unique(a, return_index=True)
185: (4)           >>> u
186: (4)           array(['a', 'b', 'c'], dtype='<U1')
187: (4)           >>> indices
188: (4)           array([0, 1, 3])
189: (4)           >>> a[indices]
190: (4)           array(['a', 'b', 'c'], dtype='<U1')
191: (4)           Reconstruct the input array from the unique values and inverse:
192: (4)           >>> a = np.array([1, 2, 6, 4, 2, 3, 2])
193: (4)           >>> u, indices = np.unique(a, return_inverse=True)
194: (4)           >>> u
195: (4)           array([1, 2, 3, 4, 6])
196: (4)           >>> indices
197: (4)           array([0, 1, 4, 3, 1, 2, 1])
198: (4)           >>> u[indices]
199: (4)           array([1, 2, 6, 4, 2, 3, 2])
200: (4)           Reconstruct the input values from the unique values and counts:
201: (4)           >>> a = np.array([1, 2, 6, 4, 2, 3, 2])
202: (4)           >>> values, counts = np.unique(a, return_counts=True)
203: (4)           >>> values

```

```

405: (4)                                 Test whether each element of a 1-D array is also present in a second
406: (4)                                 array.
407: (4)                                 Returns a boolean array the same length as `ar1` that is True

```

```

408: (4) where an element of `ar1` is in `ar2` and False otherwise.
409: (4) We recommend using :func:`isin` instead of `in1d` for new code.
410: (4) Parameters
411: (4)
412: (4) ar1 : (M,) array_like
413: (8) Input array.
414: (4) ar2 : array_like
415: (8) The values against which to test each value of `ar1`.
416: (4) assume_unique : bool, optional
417: (8) If True, the input arrays are both assumed to be unique, which
418: (8) can speed up the calculation. Default is False.
419: (4) invert : bool, optional
420: (8) If True, the values in the returned array are inverted (that is,
421: (8) False where an element of `ar1` is in `ar2` and True otherwise).
422: (8) Default is False. ``np.in1d(a, b, invert=True)`` is equivalent
423: (8) to (but is faster than) ``np.invert(np.in1d(a, b))``.
424: (4) kind : {None, 'sort', 'table'}, optional
425: (8) The algorithm to use. This will not affect the final result,
426: (8) but will affect the speed and memory use. The default, None,
427: (8) will select automatically based on memory considerations.
428: (8)
429: (10) * If 'sort', will use a mergesort-based approach. This will have
430: (10) a memory usage of roughly 6 times the sum of the sizes of
431: (8) `ar1` and `ar2`, not accounting for size of dtypes.
432: (10) * If 'table', will use a lookup table approach similar
433: (10) to a counting sort. This is only available for boolean and
434: (10) integer arrays. This will have a memory usage of the
435: (10) size of `ar1` plus the max-min value of `ar2`. `assume_unique`
436: (8) has no effect when the 'table' option is used.
437: (10) * If None, will automatically choose 'table' if
438: (10) the required memory allocation is less than or equal to
439: (10) 6 times the sum of the sizes of `ar1` and `ar2`,
440: (10) otherwise will use 'sort'. This is done to not use
441: (10) a large amount of memory by default, even though
442: (10) 'table' may be faster in most cases. If 'table' is chosen,
443: (8) `assume_unique` will have no effect.
444: (4) .. versionadded:: 1.8.0
445: (4) Returns
446: (4)
447: (8) in1d : (M,) ndarray, bool
448: (4) The values `ar1[in1d]` are in `ar2`.
449: (4) See Also
450: (4) isin : Version of this function that preserves the
451: (28) shape of ar1.
452: (4) numpy.lib.arraysetops : Module with a number of other functions for
453: (28) performing set operations on arrays.
454: (4) Notes
455: (4)
456: (4) `in1d` can be considered as an element-wise function version of the
457: (4) python keyword `in`, for 1-D sequences. ``in1d(a, b)`` is roughly
458: (4) equivalent to ``np.array([item in b for item in a])``.
459: (4) However, this idea fails if `ar2` is a set, or similar (non-sequence)
460: (4) container: As ``ar2`` is converted to an array, in those cases
461: (4) ``asarray(ar2)`` is an object array rather than the expected array of
462: (4) contained values.
463: (4) Using ``kind='table'`` tends to be faster than `kind='sort'` if the
464: (4) following relationship is true:
465: (4) ``log10(len(ar2)) > (log10(max(ar2)-min(ar2)) - 2.27) / 0.927``,
466: (4) but may use greater memory. The default value for `kind` will
467: (4) be automatically selected based only on memory usage, so one may
468: (4) manually set ``kind='table'`` if memory constraints can be relaxed.
469: (4) .. versionadded:: 1.4.0

def _isin_dispatcher(element, test_elements, assume_unique=None, invert=None,
                     *, kind=None):
    return (element, test_elements)
@array_function_dispatch(_isin_dispatcher)
def isin(element, test_elements, assume_unique=False, invert=False, *,
         kind=None):
    """
    Calculates ``element in test_elements``, broadcasting over `element` only.
    Returns a boolean array of the same shape as `element` that is True
    where an element of `element` is in `test_elements` and False otherwise.

    Parameters
    -----
    element : array_like
        Input array.
    test_elements : array_like
        The values against which to test each value of `element`.
        This argument is flattened if it is an array or array_like.
        See notes for behavior with non-array-like parameters.
    assume_unique : bool, optional
        If True, the input arrays are both assumed to be unique, which
        can speed up the calculation. Default is False.
    invert : bool, optional
        If True, the values in the returned array are inverted, as if
        calculating `element not in test_elements`. Default is False.
        ``np.isin(a, b, invert=True)`` is equivalent to (but faster
        than) ``np.invert(np.isin(a, b))``.
    kind : {None, 'sort', 'table'}, optional
        The algorithm to use. This will not affect the final result,
        but will affect the speed and memory use. The default, None,
        will select automatically based on memory considerations.
        * If 'sort', will use a mergesort-based approach. This will have
          a memory usage of roughly 6 times the sum of the sizes of
          `ar1` and `ar2`, not accounting for size of dtypes.
        * If 'table', will use a lookup table approach similar
          to a counting sort. This is only available for boolean and
          integer arrays. This will have a memory usage of the
          size of `ar1` plus the max-min value of `ar2`. `assume_unique`
          has no effect when the 'table' option is used.
    """

```

```

615: (8) * If None, will automatically choose 'table' if
616: (10) the required memory allocation is less than or equal to
617: (10) 6 times the sum of the sizes of `ar1` and `ar2`,
618: (10) otherwise will use 'sort'. This is done to not use
619: (10) a large amount of memory by default, even though
620: (10) 'table' may be faster in most cases. If 'table' is chosen,
621: (10) `assume_unique` will have no effect.
622: (4) Returns
623: (4)
624: (4) -----
625: (8) isin : ndarray, bool
626: (8) Has the same shape as `element`. The values `element[isin]`
627: (4) are in `test_elements`.
628: (4) See Also
629: (4) -----
630: (4) in1d : Flattened version of this function.
631: (28) numpy.lib.arraysetops : Module with a number of other functions for
632: (4) performing set operations on arrays.
633: (4) Notes
634: (4) -----
635: (4) `isin` is an element-wise function version of the python keyword `in`.
636: (4) ``isin(a, b)`` is roughly equivalent to
637: (4) ``np.array([item in b for item in a])`` if `a` and `b` are 1-D sequences.
638: (4) `element` and `test_elements` are converted to arrays if they are not
639: (4) already. If `test_elements` is a set (or other non-sequence collection)
640: (4) it will be converted to an object array with one element, rather than an
641: (4) array of the values contained in `test_elements`. This is a consequence
642: (4) of the `array` constructor's way of handling non-sequence collections.
643: (4) Converting the set to a list usually gives the desired behavior.
644: (4) Using ``kind='table'`` tends to be faster than `kind='sort'` if the
645: (4) following relationship is true:
646: (4) ``log10(len(ar2)) > (log10(max(ar2)-min(ar2)) - 2.27) / 0.927``,
647: (4) but may use greater memory. The default value for `kind` will
648: (4) be automatically selected based only on memory usage, so one may
649: (4) manually set ``kind='table'`` if memory constraints can be relaxed.
650: (4) .. versionadded:: 1.13.0
651: (4) Examples
652: (4) -----
653: (4) >>> element = 2*np.arange(4).reshape((2, 2))
654: (4) >>> element
655: (11) array([[0, 2],
656: (4) [4, 6]])
657: (4) >>> test_elements = [1, 2, 4, 8]
658: (4) >>> mask = np.isin(element, test_elements)
659: (4) >>> mask
660: (11) array([[False,  True],
661: (4) [ True, False]])
662: (4) >>> element[mask]
663: (4) array([2, 4])
664: (4) The indices of the matched values can be obtained with `nonzero`:
665: (4) >>> np.nonzero(mask)
666: (4) (array([0, 1]), array([1, 0]))
667: (4) The test can also be inverted:
668: (4) >>> mask = np.isin(element, test_elements, invert=True)
669: (4) >>> mask
670: (11) array([[ True, False],
671: (4) [False,  True]])
672: (4) >>> element[mask]
673: (4) array([0, 6])
674: (4) Because of how `array` handles sets, the following does not
675: (4) work as expected:
676: (4) >>> test_set = {1, 2, 4, 8}
677: (4) >>> np.isin(element, test_set)
678: (11) array([[False, False],
679: (4) [False, False]])
680: (4) Casting the set to a list gives the expected result:
681: (4) >>> np.isin(element, list(test_set))
682: (11) array([[False,  True],
683: (4) [ True, False]])
"""

```

```

684: (4)           element = np.asarray(element)
685: (4)           return in1d(element, test_elements, assume_unique=assume_unique,

## File 206 - arrayterator.py:

```

1: (0)             """
2: (0)             A buffered iterator for big arrays.
3: (0)             This module solves the problem of iterating over a big file-based array
4: (0)             without having to read it into memory. The `Arrayterator` class wraps
5: (0)             an array object, and when iterated it will return sub-arrays with at most
6: (0)             a user-specified number of elements.
7: (0)             """
8: (0)             from operator import mul
9: (0)             from functools import reduce
10: (0)            __all__ = ['Arrayterator']
11: (0)            class Arrayterator:
12: (4)             """
13: (4)             Buffered iterator for big arrays.
14: (4)             `Arrayterator` creates a buffered iterator for reading big arrays in small
15: (4)             contiguous blocks. The class is useful for objects stored in the
16: (4)             file system. It allows iteration over the object *without* reading
17: (4)             everything in memory; instead, small blocks are read and iterated over.
18: (4)             `Arrayterator` can be used with any object that supports multidimensional
19: (4)             slices. This includes NumPy arrays, but also variables from
20: (4)             Scientific.IO.NetCDF or pynetcdf for example.
21: (4)             Parameters
22: (4)             -----
23: (4)             var : array_like
24: (8)             The object to iterate over.
25: (4)             buf_size : int, optional
26: (8)             The buffer size. If `buf_size` is supplied, the maximum amount of
27: (8)             data that will be read into memory is `buf_size` elements.
28: (8)             Default is None, which will read as many element as possible
29: (8)             into memory.
30: (4)             Attributes
31: (4)             -----
32: (4)             var
33: (4)             buf_size
34: (4)             start
35: (4)             stop
36: (4)             step
37: (4)             shape
38: (4)             flat
39: (4)             See Also
40: (4)             -----
41: (4)             ndenumerate : Multidimensional array iterator.
42: (4)             flatiter : Flat array iterator.
43: (4)             memmap : Create a memory-map to an array stored in a binary file on disk.
44: (4)             Notes
45: (4)             -----
46: (4)             The algorithm works by first finding a "running dimension", along which
47: (4)             the blocks will be extracted. Given an array of dimensions
48: (4)             `` $d_1, d_2, \dots, d_n$ `` , e.g. if `buf_size` is smaller than `` $d_1$ `` , the
49: (4)             first dimension will be used. If, on the other hand,
50: (4)             `` $d_1 < buf\_size < d_1 \cdot d_2$ `` the second dimension will be used, and so on.
51: (4)             Blocks are extracted along this dimension, and when the last block is
52: (4)             returned the process continues from the next dimension, until all
53: (4)             elements have been read.
54: (4)             Examples
55: (4)             -----
56: (4)             >>> a = np.arange(3 * 4 * 5 * 6).reshape(3, 4, 5, 6)
57: (4)             >>> a_itor = np.lib.Arrayterator(a, 2)
58: (4)             >>> a_itor.shape
59: (4)             (3, 4, 5, 6)
60: (4)             Now we can iterate over ``a_itor`` , and it will return arrays of size
61: (4)             two. Since `buf_size` was smaller than any dimension, the first
```

```

62: (4) dimension will be iterated over first:
63: (4) >>> for subarr in a_itor:
64: (4) ...     if not subarr.all():

## File 207 - format.py:

```

1: (0)             """
2: (0)             Binary serialization
3: (0)             NPY format
4: (0)             =====
5: (0)             A simple format for saving numpy arrays to disk with the full
6: (0)             information about them.
7: (0)             The ``.npy`` format is the standard binary file format in NumPy for
8: (0)             persisting a *single* arbitrary NumPy array on disk. The format stores all
9: (0)             of the shape and dtype information necessary to reconstruct the array
10: (0)            correctly even on another machine with a different architecture.
11: (0)            The format is designed to be as simple as possible while achieving
12: (0)            its limited goals.
13: (0)            The ``.npz`` format is the standard format for persisting *multiple* NumPy
14: (0)            arrays on disk. A ``.npz`` file is a zip file containing multiple ``.npy``
15: (0)            files, one for each array.
16: (0)            Capabilities
17: (0)            -----
18: (0)            - Can represent all NumPy arrays including nested record arrays and
19: (2)            object arrays.
20: (0)            - Represents the data in its native binary form.
21: (0)            - Supports Fortran-contiguous arrays directly.
22: (0)            - Stores all of the necessary information to reconstruct the array
23: (2)            including shape and dtype on a machine of a different
24: (2)            architecture. Both little-endian and big-endian arrays are
25: (2)            supported, and a file with little-endian numbers will yield
26: (2)            a little-endian array on any machine reading the file. The

```

27: (2) types are described in terms of their actual sizes. For example,  
 28: (2) if a machine with a 64-bit C "long int" writes out an array with  
 29: (2) "long ints", a reading machine with 32-bit C "long ints" will yield  
 30: (2) an array with 64-bit integers.  
 31: (0) - Is straightforward to reverse engineer. Datasets often live longer than  
 32: (2) the programs that created them. A competent developer should be  
 33: (2) able to create a solution in their preferred programming language to  
 34: (2) read most ``.npy`` files that they have been given without much  
 35: (2) documentation.  
 36: (0) - Allows memory-mapping of the data. See `open\_memmap`.  
 37: (0) - Can be read from a filelike stream object instead of an actual file.  
 38: (0) - Stores object arrays, i.e. arrays containing elements that are arbitrary  
 39: (2) Python objects. Files with object arrays are not to be mmapable, but  
 40: (2) can be read and written to disk.

41: (0) Limitations  
 42: (0) -----  
 43: (0) - Arbitrary subclasses of numpy.ndarray are not completely preserved.  
 44: (2) Subclasses will be accepted for writing, but only the array data will  
 45: (2) be written out. A regular numpy.ndarray object will be created  
 46: (2) upon reading the file.

47: (0) .. warning::  
 48: (2) Due to limitations in the interpretation of structured dtypes, dtypes  
 49: (2) with fields with empty names will have the names replaced by 'f0', 'f1',  
 50: (2) etc. Such arrays will not round-trip through the format entirely  
 51: (2) accurately. The data is intact; only the field names will differ. We are  
 52: (2) working on a fix for this. This fix will not require a change in the  
 53: (2) file format. The arrays with such structures can still be saved and  
 54: (2) restored, and the correct dtype may be restored by using the  
 55: (2) ``loadedarray.view(correct\_dtype)`` method.

56: (0) File extensions  
 57: (0) -----  
 58: (0) We recommend using the ``.npy`` and ``.npz`` extensions for files saved  
 59: (0) in this format. This is by no means a requirement; applications may wish  
 60: (0) to use these file formats but use an extension specific to the  
 61: (0) application. In the absence of an obvious alternative, however,  
 62: (0) we suggest using ``.npy`` and ``.npz``.

63: (0) Version numbering  
 64: (0) -----  
 65: (0) The version numbering of these formats is independent of NumPy version  
 66: (0) numbering. If the format is upgraded, the code in `numpy.io` will still  
 67: (0) be able to read and write Version 1.0 files.

68: (0) Format Version 1.0  
 69: (0) -----  
 70: (0) The first 6 bytes are a magic string: exactly ``\\x93NUMPY``.  
 71: (0) The next 1 byte is an unsigned byte: the major version number of the file  
 72: (0) format, e.g. ``\\x01``.  
 73: (0) The next 1 byte is an unsigned byte: the minor version number of the file  
 74: (0) format, e.g. ``\\x00``. Note: the version of the file format is not tied  
 75: (0) to the version of the numpy package.  
 76: (0) The next 2 bytes form a little-endian unsigned short int: the length of  
 77: (0) the header data HEADER\_LEN.  
 78: (0) The next HEADER\_LEN bytes form the header data describing the array's  
 79: (0) format. It is an ASCII string which contains a Python literal expression  
 80: (0) of a dictionary. It is terminated by a newline (``\\n``) and padded with  
 81: (0) spaces (``\\x20``) to make the total of  
 82: (0) ``len(magic string) + 2 + len(length) + HEADER\_LEN`` be evenly divisible  
 83: (0) by 64 for alignment purposes.  
 84: (0) The dictionary contains three keys:  
 85: (4)    "descr" : dtype.descr  
 86: (6)     An object that can be passed as an argument to the `numpy.dtype`  
 87: (6)     constructor to create the array's dtype.  
 88: (4)    "fortran\_order" : bool  
 89: (6)     Whether the array data is Fortran-contiguous or not. Since  
 90: (6)     Fortran-contiguous arrays are a common form of non-C-contiguity,  
 91: (6)     we allow them to be written directly to disk for efficiency.  
 92: (4)    "shape" : tuple of int  
 93: (6)     The shape of the array.  
 94: (0) For repeatability and readability, the dictionary keys are sorted in  
 95: (0) alphabetic order. This is for convenience only. A writer SHOULD implement

```

96: (0) this if possible. A reader MUST NOT depend on this.
97: (0) Following the header comes the array data. If the dtype contains Python
98: (0) objects (i.e. ``dtype.hasobject is True``), then the data is a Python
99: (0) pickle of the array. Otherwise the data is the contiguous (either C-
100: (0) or Fortran-, depending on ``fortran_order``) bytes of the array.
101: (0) Consumers can figure out the number of bytes by multiplying the number
102: (0) of elements given by the shape (noting that ``shape=()`` means there is
103: (0) 1 element) by ``dtype.itemsize``.
104: (0) Format Version 2.0
105: (0) -----
106: (0) The version 1.0 format only allowed the array header to have a total size of
107: (0) 65535 bytes. This can be exceeded by structured arrays with a large number of
108: (0) columns. The version 2.0 format extends the header size to 4 GiB.
109: (0) `numpy.save` will automatically save in 2.0 format if the data requires it,
110: (0) else it will always use the more compatible 1.0 format.
111: (0) The description of the fourth element of the header therefore has become:
112: (0) "The next 4 bytes form a little-endian unsigned int: the length of the header
113: (0) data HEADER_LEN."
114: (0) Format Version 3.0
115: (0) -----
116: (0) This version replaces the ASCII string (which in practice was latin1) with
117: (0) a utf8-encoded string, so supports structured types with any unicode field
118: (0) names.
119: (0) Notes
120: (0) -----
121: (0) The ``.npy`` format, including motivation for creating it and a comparison of
122: (0) alternatives, is described in the
123: (0) :doc:`"npy-format" NEP <neps:nep-0001-npy-format>`, however details have
124: (0) evolved with time and this document is more current.

    -----
    fp : file_like object
        If this is not a real file object, then this may take extra memory
        and time.
    allow_pickle : bool, optional
        Whether to allow writing pickled data. Default: False
        .. versionchanged:: 1.16.3
            Made default False in response to CVE-2019-6446.
    pickle_kwds : dict
        Additional keyword arguments to pass to pickle.load. These are only
        useful when loading object arrays saved on Python 2 when using
        Python 3.
    max_header_size : int, optional
        Maximum allowed size of the header. Large headers may not be safe
        to load securely and thus require explicitly passing a larger value.
        See :py:func:`ast.literal_eval()` for details.
        This option is ignored when `allow_pickle` is passed. In that case
        the file is by definition trusted and the limit is unnecessary.

Returns
-----
array : ndarray
    The array from the data on disk.

Raises
-----
ValueError
    If the data is invalid, or allow_pickle=False and the file contains
    an object array.

118: (0) @array_function_dispatch(_rot90_dispatcher)
119: (0) def rot90(m, k=1, axes=(0, 1)):
120: (4) """
121: (4)     Rotate an array by 90 degrees in the plane specified by axes.
122: (4)     Rotation direction is from the first towards the second axis.
123: (4)     This means for a 2D array with the default `k` and `axes`, the
124: (4)     rotation will be counterclockwise.
125: (4) Parameters
126: (4) -----
127: (4) m : array_like
128: (8)     Array of two or more dimensions.
129: (4) k : integer
130: (8)     Number of times the array is rotated by 90 degrees.
131: (4) axes : (2,) array_like
132: (8)     The array is rotated in the plane defined by the axes.
133: (8)     Axes must be different.
134: (8)     .. versionadded:: 1.12.0
135: (4) Returns
136: (4) -----
137: (4) y : ndarray
138: (8)     A rotated view of `m`.
139: (4) See Also
140: (4) -----
141: (4) flip : Reverse the order of elements in an array along the given axis.
142: (4) fliplr : Flip an array horizontally.
143: (4) flipud : Flip an array vertically.
144: (4) Notes
145: (4) -----
146: (4) ```rot90(m, k=1, axes=(1,0))``` is the reverse of
147: (4) ```rot90(m, k=1, axes=(0,1))``` .
148: (4) ```rot90(m, k=1, axes=(1,0))``` is equivalent to
149: (4) ```rot90(m, k=-1, axes=(0,1))``` .
150: (4) Examples
151: (4) -----
152: (4) >>> m = np.array([[1,2],[3,4]], int)
153: (4) >>> m
154: (4) array([[1, 2],

    Reverse the order of elements in an array along the given axis.
    The shape of the array is preserved, but the elements are reordered.
    .. versionadded:: 1.12.0
    Parameters
    -----
    m : array_like
        Input array.
    axis : None or int or tuple of ints, optional
        Axis or axes along which to flip over. The default,
        axis=None, will flip over all of the axes of the input array.
        If axis is negative it counts from the last to the first axis.
        If axis is a tuple of ints, flipping is performed on all of the axes
        specified in the tuple.
        .. versionchanged:: 1.15.0
        None and tuples of axes are supported
    Returns
    -----
    out : array_like
        A view of `m` with the entries of axis reversed. Since a view is
        returned, this operation is done in constant time.
    See Also
    -----
    flipud : Flip an array vertically (axis=0).
    fliplr : Flip an array horizontally (axis=1).
    Notes
    -----
    flip(m, 0) is equivalent to flipud(m).
    flip(m, 1) is equivalent to fliplr(m).
    flip(m, n) corresponds to ``m[...,:-1,...]`` with ``::-1`` at position n.
    flip(m) corresponds to ``m[::-1,:,:-1,...,:-1]`` with ``::-1`` at all
    positions.
    flip(m, (0, 1)) corresponds to ``m[::-1,:,:-1,...]`` with ``::-1`` at
    position 0 and position 1.
    Examples
    -----

313: (12)            keepdims=np._NoValue):
314: (4)          """
315: (4)          Compute the weighted average along the specified axis.
316: (4)          Parameters
317: (4)          -----
318: (4)          a : array_like
319: (8)          Array containing data to be averaged. If `a` is not an array, a
320: (8)          conversion is attempted.
321: (4)          axis : None or int or tuple of ints, optional
322: (8)          Axis or axes along which to average `a`. The default,
323: (8)          axis=None, will average over all of the elements of the input array.
324: (8)          If axis is negative it counts from the last to the first axis.
325: (8)          .. versionadded:: 1.7.0
326: (8)          If axis is a tuple of ints, averaging is performed on all of the axes
327: (8)          specified in the tuple instead of a single axis or all the axes as
328: (8)          before.
329: (4)          weights : array_like, optional
330: (8)          An array of weights associated with the values in `a`. Each value in
331: (8)          `a` contributes to the average according to its associated weight.
332: (8)          The weights array can either be 1-D (in which case its length must be
333: (8)          the size of `a` along the given axis) or of the same shape as `a`.
334: (8)          If `weights=None`, then all data in `a` are assumed to have a
335: (8)          weight equal to one. The 1-D calculation is::
336: (12)          avg = sum(a * weights) / sum(weights)
337: (8)          The only constraint on `weights` is that `sum(weights)` must not be 0.
338: (4)          returned : bool, optional
339: (8)          Default is `False`. If `True`, the tuple (`average`, `sum_of_weights`)
340: (8)          is returned, otherwise only the average is returned.
341: (8)          If `weights=None`, `sum_of_weights` is equivalent to the number of
342: (8)          elements over which the average is taken.
343: (4)          keepdims : bool, optional
344: (8)          If this is set to True, the axes which are reduced are left
345: (8)          in the result as dimensions with size one. With this option,
346: (8)          the result will broadcast correctly against the original `a`.
347: (8)          *Note:* `keepdims` will not work with instances of `numpy.matrix`
348: (8)          or other classes whose methods do not support `keepdims`.
349: (8)          .. versionadded:: 1.23.0
350: (4)          Returns
351: (4)          -----
352: (4)          retval, [sum_of_weights] : array_type or double
353: (8)          Return the average along the specified axis. When `returned` is
`True`,
354: (8)          return a tuple with the average as the first element and the sum
355: (8)          of the weights as the second element. `sum_of_weights` is of the
356: (8)          same type as `retval`. The result dtype follows a general pattern.
357: (8)          If `weights` is None, the result dtype will be that of `a` , or
`float64` .
358: (8)          if `a` is integral. Otherwise, if `weights` is not None and `a` is
non-
359: (8)          integral, the result type will be the type of lowest precision capable
of
360: (8)          representing values of both `a` and `weights`. If `a` happens to be
361: (8)          integral, the previous rules still applies but the result dtype will
362: (8)          at least be ``float64``.
363: (4)          Raises
364: (4)          -----

```

```

516: (4) """
517: (4)     Evaluate a piecewise-defined function.
518: (4)     Given a set of conditions and corresponding functions, evaluate each
519: (4)     function on the input data wherever its condition is true.
520: (4)     Parameters
521: (4)     -----
522: (8)     x : ndarray or scalar
523: (4)         The input domain.
524: (8)     condlist : list of bool arrays or bool scalars
525: (8)         Each boolean array corresponds to a function in `funclist`. Wherever
526: (8)         `condlist[i]` is True, `funclist[i](x)` is used as the output value.
527: (8)         Each boolean array in `condlist` selects a piece of `x`,
528: (8)         and should therefore be of the same shape as `x`.
529: (8)         The length of `condlist` must correspond to that of `funclist`.
530: (8)         If one extra function is given, i.e. if
531: (8)             ``len(funclist) == len(condlist) + 1``,
532: (8)             then that extra function
533: (8)             is the default value, used wherever all conditions are false.
534: (8)     funclist : list of callables, f(x,*args,**kw), or scalars
535: (8)         Each function is evaluated over `x` wherever its corresponding
536: (8)         condition is True. It should take a 1d array as input and give an 1d
537: (8)         array or a scalar value as output. If, instead of a callable,
538: (4)             a scalar is provided then a constant function (``lambda x: scalar``)
539: (8)         assumed.
540: (8)     args : tuple, optional
541: (8)         Any further arguments given to `piecewise` are passed to the functions
542: (8)         upon execution, i.e., if called ``piecewise(..., ..., 1, 'a')``,
543: (8)         then each function is called as ``f(x, 1, 'a')``.
544: (8)     kw : dict, optional
545: (8)         Keyword arguments used in calling `piecewise` are passed to the
546: (8)         functions upon execution, i.e., if called
547: (4)             ``piecewise(..., ..., alpha=1)``,
548: (4)             then each function is called as
549: (4)                 ``f(x, alpha=1)``.
550: (8)     Returns
551: (8)     -----
552: (8)     out : ndarray
553: (8)         The output is the same shape and type as x and is found by
554: (8)         calling the functions in `funclist` on the appropriate portions of
555: (8)         `x`,
556: (8)         as defined by the boolean arrays in `condlist`. Portions not covered
557: (8)         by any condition have a default value of 0.
558: (4)     See Also
559: (4)     -----
560: (4)     choose, select, where
561: (4)     Notes
562: (4)     -----
563: (12)     This is similar to choose or select, except that functions are
564: (12)     evaluated on elements of `x` that satisfy the corresponding condition from
565: (6)     `condlist`.
566: (12)     The result is::
567: (12)         |--
568: (12)             |funclist[0](x[condlist[0]])
569: (12)             |out = |funclist[1](x[condlist[1]])
570: (12)             |...

694: (8)                  Controls the memory layout of the copy. 'C' means C-order,
695: (8)                  'F' means F-order, 'A' means 'F' if `a` is Fortran contiguous,
696: (8)                  'C' otherwise. 'K' means match the layout of `a` as closely
697: (8)                  as possible. (Note that this function and :meth:`ndarray.copy` are
very

```

```

698: (8)           similar, but have different default values for their order-
699: (8)           arguments.)
700: (4)           subok : bool, optional
701: (8)           If True, then sub-classes will be passed-through, otherwise the
702: (8)           returned array will be forced to be a base-class array (defaults to
False).
703: (8)           .. versionadded:: 1.19.0
704: (4)           Returns
705: (4)           -----
706: (4)           arr : ndarray
707: (8)           Array interpretation of `a`.
708: (4)           See Also
709: (4)           -----
710: (4)           ndarray.copy : Preferred method for creating an array copy
711: (4)           Notes
712: (4)           -----
713: (4)           This is equivalent to:
714: (4)           >>> np.array(a, copy=True) #doctest: +SKIP
715: (4)           Examples
716: (4)           -----
717: (4)           Create an array x, with a reference y and a copy z:
718: (4)           >>> x = np.array([1, 2, 3])
719: (4)           >>> y = x
720: (4)           >>> z = np.copy(x)
721: (4)           Note that, when we modify x, y changes, but not z:
722: (4)           >>> x[0] = 10
723: (4)           >>> x[0] == y[0]
724: (4)           True
725: (4)           >>> x[0] == z[0]
726: (4)           False
727: (4)           Note that, np.copy clears previously set WRITEABLE=False flag.
728: (4)           >>> a = np.array([1, 2, 3])
729: (4)           >>> a.flags["WRITEABLE"] = False
730: (4)           >>> b = np.copy(a)
731: (4)           >>> b.flags["WRITEABLE"]
732: (4)           True
733: (4)           >>> b[0] = 3
734: (4)           >>> b
735: (4)           array([3, 2, 3])
736: (4)           Note that np.copy is a shallow copy and will not copy object
737: (4)           elements within arrays. This is mainly important for arrays
738: (4)           containing Python objects. The new array will contain the
739: (4)           same object which may lead to surprises if that object can
740: (4)           be modified (is mutable):
741: (4)           >>> a = np.array([1, 'm', [2, 3, 4]], dtype=object)
742: (4)           >>> b = np.copy(a)
743: (4)           >>> b[2][0] = 10
744: (4)           >>> a
745: (4)           array([1, 'm', list([10, 3, 4])], dtype=object)
746: (4)           To ensure all elements within an ``object`` array are copied,
747: (4)           use `copy.deepcopy`:
748: (4)           >>> import copy
749: (4)           >>> a = np.array([1, 'm', [2, 3, 4]], dtype=object)
750: (4)           >>> c = copy.deepcopy(a)
751: (4)           >>> c[2][0] = 10
752: (4)           >>> c
753: (4)           array([1, 'm', list([10, 3, 4])], dtype=object)
754: (4)           >>> a
755: (4)           array([1, 'm', list([2, 3, 4])], dtype=object)
756: (4)           """
757: (4)           return array(a, order=order, subok=subok, copy=True)
758: (0)           def _gradient_dispatcher(f, *varargs, axis=None, edge_order=None):
759: (4)               yield f
760: (4)               yield from varargs
761: (0)               @array_function_dispatch(_gradient_dispatcher)
762: (0)               def gradient(f, *varargs, axis=None, edge_order=1):
763: (4)                   """
764: (4)                   Return the gradient of an N-dimensional array.
765: (4)                   The gradient is computed using second order accurate central differences

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

766: (4)           in the interior points and either first or second order accurate one-sides
767: (4)           (forward or backwards) differences at the boundaries.
768: (4)           The returned gradient hence has the same shape as the input array.
769: (4)           Parameters
770: (4)           -----
771: (4)           f : array_like
772: (8)             An N-dimensional array containing samples of a scalar function.
773: (4)           varargs : list of scalar or array, optional
774: (8)             Spacing between f values. Default unitary spacing for all dimensions.
775: (8)             Spacing can be specified using:
776: (8)               1. single scalar to specify a sample distance for all dimensions.
777: (8)               2. N scalars to specify a constant sample distance for each dimension.
778: (11)                 i.e. `dx`, `dy`, `dz`, ...
779: (8)               3. N arrays to specify the coordinates of the values along each
780: (11)                 dimension of F. The length of the array must match the size of
781: (11)                 the corresponding dimension
782: (8)               4. Any combination of N scalars/arrays with the meaning of 2. and 3.
783: (8)             If `axis` is given, the number of varargs must equal the number of
784: axes.
785: (8)             Default: 1.
786: (4)           edge_order : {1, 2}, optional
787: (8)             Gradient is calculated using N-th order accurate differences
788: (8)             at the boundaries. Default: 1.
789: (8)               .. versionadded:: 1.9.1
790: (4)           axis : None or int or tuple of ints, optional
791: (8)             Gradient is calculated only along the given axis or axes
792: axes
793: (8)             The default (axis = None) is to calculate the gradient for all the
794: of the input array. axis may be negative, in which case it counts from
795: the last to the first axis.
796: (8)               .. versionadded:: 1.11.0
797: (4)           Returns
798: (8)           -----
799: (4)           gradient : ndarray or list of ndarray
800: (8)             A list of ndarrays (or a single ndarray if there is only one
801: dimension)
802: (4)             corresponding to the derivatives of f with respect to each dimension.
803: (4)             Each derivative has the same shape as f.
804: (4)           Examples
805: (4)           -----
806: (4)           >>> f = np.array([1, 2, 4, 7, 11, 16], dtype=float)
807: (4)           >>> np.gradient(f)
808: (4)             array([1. , 1.5, 2.5, 3.5, 4.5, 5. ])
809: coordinates
810: (4)             Spacing can be also specified with an array that represents the
811: of the values F along the dimensions.
812: (4)             For instance a uniform spacing:
813: (4)             >>> x = np.arange(f.size)
814: (4)             >>> np.gradient(f, x)
815: (4)             array([1. , 1.5, 2.5, 3.5, 4.5, 5. ])
816: (4)             Or a non uniform one:
817: (4)             >>> x = np.array([0., 1., 1.5, 3.5, 4., 6.], dtype=float)
818: (4)             >>> np.gradient(f, x)
819: (4)             array([1. , 3. , 3.5, 6.7, 6.9, 2.5])
820: (4)             For two dimensional arrays, the return will be two arrays ordered by
821: axis. In this example the first array stands for the gradient in
822: rows and the second one in columns direction:
823: (4)             >>> np.gradient(np.array([[1, 2, 6], [3, 4, 5]]), dtype=float))
824: (4)             [array([[ 2.,  2., -1.],
825: (11)                   [ 2.,  2., -1.]]), array([[1. , 2.5, 4. ],
826: (11)                   [1. , 1. , 1. ]]])
827: (4)             In this example the spacing is also specified:
828: (4)             uniform for axis=0 and non uniform for axis=1
829: (4)             >>> dx = 2.
830: (4)             >>> y = [1., 1.5, 3.5]
831: (4)             >>> np.gradient(np.array([[1, 2, 6], [3, 4, 5]]), dtype=float), dx, y)
832: (4)             [array([[ 1. ,  1. , -0.5],
```

```

831: (11) [ 1. , 1. , -0.5]], array([[2. , 2. , 2. ],
832: (11) [2. , 1.7, 0.5]])
833: (4) It is possible to specify how boundaries are treated using `edge_order`:
834: (4) >>> x = np.array([0, 1, 2, 3, 4])
835: (4) >>> f = x**2
836: (4) >>> np.gradient(f, edge_order=1)
837: (4) array([1., 2., 4., 6., 7.])
838: (4) >>> np.gradient(f, edge_order=2)
839: (4) array([0., 2., 4., 6., 8.])
840: (4) The `axis` keyword can be used to specify a subset of axes of which the
841: (4) gradient is calculated
842: (4) >>> np.gradient(np.array([[1, 2, 6], [3, 4, 5]]), dtype=float), axis=0)
843: (4) array([[ 2.,  2., -1.],
844: (11) [ 2.,  2., -1.]])
845: (4) Notes
846: (4) -----
847: (4) Assuming that :math:`f \in C^3` (i.e., :math:`f` has at least 3
848: (4) continuous
849: (4) derivatives) and let :math:`h_{\cdot i}` be a non-homogeneous stepsize, we
gradient minimize the "consistency error" :math:`\|\eta_i\|` between the true
850: (4) and its estimate from a linear combination of the neighboring grid-points:
851: (4) .. math::
852: (8) 
$$\|\eta_i\| = f_{\cdot i}^{\prime \prime}(x_i) - \left[ \alpha f(x_i) + \beta f(x_i + h_d) + \gamma f(x_i - h_s) \right]$$

853: (20)
854: (28)
855: (28)
856: (20)
857: (4) By substituting :math:`f(x_i + h_d)` and :math:`f(x_i - h_s)` with their Taylor series expansion, this translates into solving
858: (4) the following the linear system:
859: (4) .. math::
860: (4) .. math::
861: (8) 
$$\begin{array}{l} \left( \alpha + \beta + \gamma \right) h_d = 0 \\ \beta h_d - \gamma h_s = 1 \\ \beta h_d^2 + \gamma h_s^2 = 0 \end{array}$$

862: (12)
863: (16)
864: (16)
865: (16)
866: (12)
867: (8)
868: (4) The resulting approximation of :math:`f_{\cdot i}^{\prime \prime}(1)` is the following:
869: (4) .. math::
870: (8) .. math::
871: (12) 
$$\hat{f}_{\cdot i}^{\prime \prime}(1) = \frac{h_s^2 f(x_i + h_d) + (h_d^2 - h_s^2) f(x_i) - h_d^2 f(x_i - h_s)}{2 h_d^2}$$

872: (16)
873: (16)
874: (16)
875: (16)
876: (12)
877: (32)
878: (32)
879: (4) It is worth noting that if :math:`h_s = h_d` (i.e., data are evenly spaced)
880: (4) we find the standard second order approximation:
881: (4) .. math::
882: (4) .. math::
883: (8) .. math::
884: (12) 
$$\hat{f}_{\cdot i}^{\prime \prime}(1) = \frac{f(x_{i+1}) - f(x_{i-1})}{2h} + \frac{h^2}{12} \mathcal{O}(h^2)$$

885: (12)
886: (4) With a similar procedure the forward/backward approximations used for
887: (4) boundaries can be derived.

1031: (4)              Calculate the n-th discrete difference along the given axis.

```

```

1032: (4)          The first difference is given by ``out[i] = a[i+1] - a[i]`` along
1033: (4)          the given axis, higher differences are calculated by using `diff`
1034: (4)          recursively.
1035: (4)          Parameters
1036: (4)          -----
1037: (4)          a : array_like
1038: (8)            Input array
1039: (4)          n : int, optional
1040: (8)            The number of times values are differenced. If zero, the input
1041: (8)            is returned as-is.
1042: (4)          axis : int, optional
1043: (8)            The axis along which the difference is taken, default is the
1044: (8)            last axis.
1045: (4)          prepend, append : array_like, optional
1046: (8)            Values to prepend or append to `a` along axis prior to
1047: (8)            performing the difference. Scalar values are expanded to
1048: (8)            arrays with length 1 in the direction of axis and the shape
1049: (8)            of the input array in along all other axes. Otherwise the
1050: (8)            dimension and shape must match `a` except along axis.
1051: (8)            .. versionadded:: 1.16.0
1052: (4)          Returns
1053: (4)          -----
1054: (4)          diff : ndarray
1055: (8)            The n-th differences. The shape of the output is the same as `a`
1056: (8)            except along `axis` where the dimension is smaller by `n`. The
1057: (8)            type of the output is the same as the type of the difference
1058: (8)            between any two elements of `a`. This is the same as the type of
1059: (8)            `a` in most cases. A notable exception is `datetime64`, which
1060: (8)            results in a `timedelta64` output array.
1061: (4)          See Also
1062: (4)          -----
1063: (4)          gradient, ediff1d, cumsum
1064: (4)          Notes
1065: (4)          -----
1066: (4)            Type is preserved for boolean arrays, so the result will contain
1067: (4)            `False` when consecutive elements are the same and `True` when they
1068: (4)            differ.
1069: (4)            For unsigned integer arrays, the results will also be unsigned. This
1070: (4)            should not be surprising, as the result is consistent with
1071: (4)            calculating the difference directly:
1072: (4)            >>> u8_arr = np.array([1, 0], dtype=np.uint8)
1073: (4)            >>> np.diff(u8_arr)
1074: (4)            array([255], dtype=uint8)
1075: (4)            >>> u8_arr[1,...] - u8_arr[0,...]
1076: (4)            255
1077: (4)            If this is not desirable, then the array should be cast to a larger
1078: (4)            integer type first:
1079: (4)            >>> i16_arr = u8_arr.astype(np.int16)
1080: (4)            >>> np.diff(i16_arr)
1081: (4)            array([-1], dtype=int16)
1082: (4)          Examples
1083: (4)          -----
1084: (4)            >>> x = np.array([1, 2, 4, 7, 0])
1085: (4)            >>> np.diff(x)
1086: (4)            array([ 1,  2,  3, -7])

1297: (4)     """
1298: (4)     Unwrap by taking the complement of large deltas with respect to the
1299: (4)     period.
1300: (4)     This unwraps a signal `p` by changing elements which have an absolute
1301: (4)     difference from their predecessor of more than ``max(discont, period/2)``
1302: (4)     to their `period`-complementary values.
1303: (4)     For the default case where `period` is :math:`2\pi` and `discont` is
:math:`\pi`, this unwraps a radian phase `p` such that adjacent

```

```

differences
1304: (4)     are never greater than :math:`\pi` by adding :math:`2k\pi` for some
1305: (4)     integer :math:`k`.
1306: (4)     Parameters
1307: (4)     -----
1308: (4)     p : array_like
1309: (8)       Input array.
1310: (4)     discontinuity : float, optional
1311: (8)       Maximum discontinuity between values, default is ``period/2``.
1312: (8)       Values below ``period/2`` are treated as if they were ``period/2``.
1313: (8)       To have an effect different from the default, `discont` should be
1314: (8)       larger than ``period/2``.
1315: (4)     axis : int, optional
1316: (8)       Axis along which unwrap will operate, default is the last axis.
1317: (4)     period : float, optional
1318: (8)       Size of the range over which the input wraps. By default, it is
1319: (8)       ``2 pi``.
1320: (8)       .. versionadded:: 1.21.0

1662: (4)     return arrays
1663: (0) @set_module('numpy')
1664: (0) class vectorize:
1665: (4)     """
1666: (4)     vectorize(pyfunc=np._NoValue, otypes=None, doc=None, excluded=None,
1667: (4)         cache=False, signature=None)
1668: (4)     Returns an object that acts like pyfunc, but takes arrays as input.
1669: (4)     Define a vectorized function which takes a nested sequence of objects or
1670: (4)     numpy arrays as inputs and returns a single numpy array or a tuple of
1671: (4)     arrays. The vectorized function evaluates `pyfunc` over successive tuples
1672: (4)     of the input arrays like the python map function, except it uses the
1673: (4)     broadcasting rules of numpy.
1674: (4)     The data type of the output of `vectorized` is determined by calling
1675: (4)     the function with the first element of the input. This can be avoided
1676: (4)     by specifying the `otypes` argument.
1677: (4)     Parameters
1678: (4)     -----
1679: (4)     pyfunc : callable, optional
1680: (8)         A python function or method.
1681: (8)         Can be omitted to produce a decorator with keyword arguments.
1682: (4)     otypes : str or list of dtypes, optional
1683: (8)         The output data type. It must be specified as either a string of
1684: (8)         typecode characters or a list of data type specifiers. There should
1685: (8)         be one data type specifier for each output.
1686: (4)     doc : str, optional
1687: (8)         The docstring for the function. If None, the docstring will be the
1688: (8)         ``pyfunc.__doc__``.
1689: (4)     excluded : set, optional
1690: (8)         Set of strings or integers representing the positional or keyword
1691: (8)         arguments for which the function will not be vectorized. These will
be
1692: (8)         passed directly to `pyfunc` unmodified.
1693: (8)         .. versionadded:: 1.7.0
1694: (4)     cache : bool, optional
1695: (8)         If `True`, then cache the first function call that determines the
number
1696: (8)         of outputs if `otypes` is not provided.
1697: (8)         .. versionadded:: 1.7.0
1698: (4)     signature : string, optional
1699: (8)         Generalized universal function signature, e.g., ``(m,n),(n)->(m)`` for
1700: (8)         vectorized matrix-vector multiplication. If provided, ``pyfunc`` will
1701: (8)         be called with (and expected to return) arrays with shapes given by
the
1702: (8)         size of corresponding core dimensions. By default, ``pyfunc`` is
1703: (8)         assumed to take scalars as input and output.
1704: (8)         .. versionadded:: 1.12.0
1705: (4)     Returns
1706: (4)     -----
1707: (4)     out : callable
1708: (8)         A vectorized function if ``pyfunc`` was provided,
1709: (8)         a decorator otherwise.
1710: (4)     See Also

```

```

1711: (4) -----
1712: (4) from numpy import frompyfunc : Takes an arbitrary Python function and returns a ufunc
1713: (4) Notes -----
1714: (4) The `vectorize` function is provided primarily for convenience, not for
1715: (4) performance. The implementation is essentially a for loop.
1716: (4) If `otypes` is not specified, then a call to the function with the
1717: (4) first argument will be used to determine the number of outputs. The
1718: (4) results of this call will be cached if `cache` is `True` to prevent
1719: (4) calling the function twice. However, to implement the cache, the
1720: (4) original function must be wrapped which will slow down subsequent
1721: (4) calls, so only do this if your function is expensive.
1722: (4) The new keyword argument interface and `excluded` argument support
1723: (4) further degrades performance.
1724: (4) References -----
1725: (4) .. [1] :doc:`/reference/c-api/generalized-ufuncs`
1726: (4) Examples -----
1727: (4) >>> def myfunc(a, b):
1728: (4) ...     "Return a-b if a>b, otherwise return a+b"
1729: (4) ...     if a > b:
1730: (4) ...         return a - b
1731: (4) ...     else:
1732: (4) ...         return a + b
1733: (4) >>> vfunc = np.vectorize(myfunc)
1734: (4) >>> vfunc([1, 2, 3, 4], 2)
1735: (4) array([3, 4, 1, 2])
1736: (4) The docstring is taken from the input function to `vectorize` unless it
1737: (4) is specified:
1738: (4) >>> vfunc.__doc__
1739: (4) 'Return a-b if a>b, otherwise return a+b'
1740: (4) >>> vfunc = np.vectorize(myfunc, doc='Vectorized `myfunc`')
1741: (4) >>> vfunc.__doc__
1742: (4) 'Vectorized `myfunc`'
1743: (4) The output type is determined by evaluating the first element of the
1744: (4) input,
1745: (4) unless it is specified:
1746: (4) >>> out = vfunc([1, 2, 3, 4], 2)
1747: (4) >>> type(out[0])
1748: (4) <class 'numpy.int64'>
1749: (4) >>> vfunc = np.vectorize(myfunc, otypes=[float])
1750: (4) >>> out = vfunc([1, 2, 3, 4], 2)
1751: (4) >>> type(out[0])
1752: (4) <class 'numpy.float64'>
1753: (4) The `excluded` argument can be used to prevent vectorizing over certain
1754: (4) arguments. This can be useful for array-like arguments of a fixed length
1755: (4) such as the coefficients for a polynomial as in `polyval`:
1756: (4) >>> def mypolyval(p, x):
1757: (4) ...     _p = list(p)
1758: (4) ...     res = _p.pop(0)
1759: (4) ...     while _p:
1760: (4) ...         res = res*x + _p.pop(0)
1761: (4) ...     return res
1762: (4) >>> vpolyval = np.vectorize(mypolyval, excluded=['p'])
1763: (4) >>> vpolyval(p=[1, 2, 3], x=[0, 1])
1764: (4) array([3, 6])
1765: (4) Positional arguments may also be excluded by specifying their position:
1766: (4) >>> vpolyval.excluded.add(0)
1767: (4) >>> vpolyval([1, 2, 3], x=[0, 1])
1768: (4) array([3, 6])
1769: (4) The `signature` argument allows for vectorizing functions that act on
1770: (4) non-scalar arrays of fixed length. For example, you can use it for a
1771: (4) vectorized calculation of Pearson correlation coefficient and its p-value:
1772: (4) >>> import scipy.stats
1773: (4) >>> pearsonr = np.vectorize(scipy.stats.pearsonr,
1774: (4) ...             signature='(n),(n)->(),()')
1775: (4) >>> pearsonr([[0, 1, 2, 3]], [[1, 2, 3, 4], [4, 3, 2, 1]])
1776: (4) (array([ 1., -1.]), array([ 0.,  0.]))
1777: (4)
1778: (4)

```

```

1779: (4)          Or for a vectorized convolution:
1780: (4)          >>> convolve = np.vectorize(np.convolve, signature='(n),(m)->(k)')
1781: (4)          >>> convolve(np.eye(4), [1, 2, 1])
1782: (4)          array([[1.,  2.,  1.,  0.,  0.,  0.],
1783: (11)             [0.,  1.,  2.,  1.,  0.,  0.],
1784: (11)             [0.,  0.,  1.,  2.,  1.,  0.],
1785: (11)             [0.,  0.,  0.,  1.,  2.,  1.]])
1786: (4)          Decorator syntax is supported. The decorator can be called as
1787: (4)          a function to provide keyword arguments.
1788: (4)          >>>@np.vectorize
1789: (4)          ...def identity(x):
1790: (4)          ...    return x

```

1986: (4)
1987: (8) m : array_like
1988: (8) A 1-D or 2-D array containing multiple variables and observations.
1989: (8) Each row of `m` represents a variable, and each column a single
1990: (4) observation of all those variables. Also see `rowvar` below.
1991: (8) y : array_like, optional
1992: (8) An additional set of variables and observations. `y` has the same form
1993: (4) as that of `m`.
1994: (8) rowvar : bool, optional
1995: (8) If `rowvar` is True (default), then each row represents a
relationship variable, with observations in the columns. Otherwise, the
1996: (8) is transposed: each column represents a variable, while the rows
1997: (8) contain observations.
1998: (4) bias : bool, optional
1999: (8) Default normalization (False) is by `` $(N - 1)$ ``, where `` $N$ `` is the
2000: (8) number of observations given (unbiased estimate). If `bias` is True,
2001: (8) then normalization is by `` $N$ ``. These values can be overridden by
using
2002: (8) the keyword ``ddof`` in numpy versions  $\geq 1.5$ .
2003: (4) ddof : int, optional
2004: (8) If not ``None`` the default value implied by `bias` is overridden.
2005: (8) Note that ``ddof=1`` will return the unbiased estimate, even if both
2006: (8) `fweights` and `aweights` are specified, and ``ddof=0`` will return
2007: (8) the simple average. See the notes for the details. The default value
2008: (8) is ``None``.
2009: (8) .. versionadded:: 1.5
2010: (4) fweights : array_like, int, optional
2011: (8) 1-D array of integer frequency weights; the number of times each
2012: (8) observation vector should be repeated.
2013: (8) .. versionadded:: 1.10
2014: (4) aweights : array_like, optional
2015: (8) 1-D array of observation vector weights. These relative weights are
2016: (8) typically large for observations considered "important" and smaller
for
2017: (8) observations considered less "important". If ``ddof=0`` the array of
2018: (8) weights can be used to assign probabilities to observation vectors.
2019: (8) .. versionadded:: 1.10
2020: (4) dtype : data-type, optional
2021: (8) Data-type of the result. By default, the return data-type will have
2022: (8) at least `numpy.float64` precision.
2023: (8) .. versionadded:: 1.20
2024: (4) Returns
2025: (4) -----
2026: (4) out : ndarray
2027: (8) The covariance matrix of the variables.
2028: (4) See Also
2029: (4) -----
2030: (4) corrcoef : Normalized covariance matrix
2031: (4) Notes
2032: (4) -----
2033: (4) Assume that the observations are in the columns of the observation
2034: (4) array `m` and let ``f = fweights`` and ``a = aweights`` for brevity. The
2035: (4) steps to compute the weighted covariance are as follows::
2036: (8) >>> m = np.arange(10, dtype=np.float64)
2037: (8) >>> f = np.arange(10) * 2
2038: (8) >>> a = np.arange(10) ** 2.
2039: (8) >>> ddof = 1
2040: (8) >>> w = f * a
2041: (8) >>> v1 = np.sum(w)
2042: (8) >>> v2 = np.sum(w * a)
2043: (8) >>> m -= np.sum(m * w, axis=None, keepdims=True) / v1
2044: (8) >>> cov = np.dot(m * w, m.T) * v1 / (v1**2 - ddof * v2)
2045: (4) Note that when ``a == 1``, the normalization factor
2046: (4) ``v1 / (v1**2 - ddof * v2)`` goes over to ``1 / (np.sum(f) - ddof)``
2047: (4) as it should.
2048: (4) Examples
2049: (4) -----
2050: (4) Consider two variables, :math:`x_0` and :math:`x_1`, which
2051: (4) correlate perfectly, but in opposite directions:
```

    >>> x = np.array([[0, 2], [1, 1], [2, 0]]).T
    >>> x
    array([[0, 1, 2],
           [2, 1, 0]])
    Note how :math:`x_0` increases while :math:`x_1` decreases. The covariance
    matrix shows this clearly:
    >>> np.cov(x)
    array([[ 1., -1.],
           [-1.,  1.]])
    Note that element :math:`C_{0,1}`, which shows the correlation between
    :math:`x_0` and :math:`x_1`, is negative.
    Further, note how `x` and `y` are combined:
    >>> x = [-2.1, -1, 4.3]
    >>> y = [3, 1.1, 0.12]
    >>> X = np.stack((x, y), axis=0)
    >>> np.cov(X)
    array([[11.71      , -4.286      ], # may vary
           [-4.286      ,  2.144133]])]
    >>> np.cov(x, y)
    array([[11.71      , -4.286      ], # may vary
           [-4.286      ,  2.144133]])]
    >>> np.cov(x)
    array(11.71)

2167: (4)                     Please refer to the documentation for `cov` for more detail. The
2168: (4)                     relationship between the correlation coefficient matrix, `R`, and the
2169: (4)                     covariance matrix, `C`, is
2170: (4)                     .. math:: R_{ij} = \frac{C_{ij}}{\sqrt{C_{ii} C_{jj}}}
2171: (4)                     The values of `R` are between -1 and 1, inclusive.
2172: (4)                     Parameters
2173: (4)                     -----
2174: (4)                     x : array_like
2175: (8)                         A 1-D or 2-D array containing multiple variables and observations.
2176: (8)                         Each row of `x` represents a variable, and each column a single
2177: (8)                         observation of all those variables. Also see `rowvar` below.
2178: (4)                     y : array_like, optional
2179: (8)                         An additional set of variables and observations. `y` has the same
2180: (8)                         shape as `x`.
2181: (4)                     rowvar : bool, optional
2182: (8)                         If `rowvar` is True (default), then each row represents a
2183: (8)                         variable, with observations in the columns. Otherwise, the
2184: (8)                         is transposed: each column represents a variable, while the rows
2185: (8)                         contain observations.
2186: (4)                     bias : _NoValue, optional
2187: (8)                         Has no effect, do not use.
2188: (8)                         .. deprecated:: 1.10.0

```

```

2189: (4)           ddof : _NoValue, optional
2190: (8)             Has no effect, do not use.
2191: (8)               .. deprecated:: 1.10.0
2192: (4)             dtype : data-type, optional
2193: (8)               Data-type of the result. By default, the return data-type will have
2194: (8)               at least `numpy.float64` precision.
2195: (8)               .. versionadded:: 1.20
2196: (4)             Returns
2197: (4)             -----
2198: (4)             R : ndarray
2199: (8)               The correlation coefficient matrix of the variables.
2200: (4)             See Also
2201: (4)             -----
2202: (4)             cov : Covariance matrix
2203: (4)             Notes
2204: (4)             -----
2205: (4)             Due to floating point rounding the resulting array may not be Hermitian,
2206: (4)             the diagonal elements may not be 1, and the elements may not satisfy the
2207: (4)             inequality  $\text{abs}(a) \leq 1$ . The real and imaginary parts are clipped to the
2208: (4)             interval [-1, 1] in an attempt to improve on that situation but is not
2209: (4)             much help in the complex case.
2210: (4)             This function accepts but discards arguments `bias` and `ddof`. This is
2211: (4)             for backwards compatibility with previous versions of this function.

These
2212: (4)             arguments had no effect on the return values of the function and can be
2213: (4)             safely ignored in this and previous versions of numpy.

Examples
2215: (4)             -----
2216: (4)             In this example we generate two random arrays, ``xarr`` and ``yarr``, and
2217: (4)             compute the row-wise and column-wise Pearson correlation coefficients,
2218: (4)             ``R``. Since ``rowvar`` is true by default, we first find the row-wise
2219: (4)             Pearson correlation coefficients between the variables of ``xarr``.
2220: (4)             >>> import numpy as np
2221: (4)             >>> rng = np.random.default_rng(seed=42)
2222: (4)             >>> xarr = rng.random((3, 3))
2223: (4)             >>> xarr
2224: (4)             array([[0.77395605, 0.43887844, 0.85859792],
2225: (11)                 [0.69736803, 0.09417735, 0.97562235],
2226: (11)                 [0.7611397 , 0.78606431, 0.12811363]])
2227: (4)             >>> R1 = np.corrcoef(xarr)
2228: (4)             >>> R1
2229: (4)             array([[ 1.          ,  0.99256089, -0.68080986],
2230: (11)                 [ 0.99256089,  1.          , -0.76492172],
2231: (11)                 [-0.68080986, -0.76492172,  1.          ]])
2232: (4)             If we add another set of variables and observations ``yarr``, we can
2233: (4)             compute the row-wise Pearson correlation coefficients between the
2234: (4)             variables in ``xarr`` and ``yarr``.
2235: (4)             >>> yarr = rng.random((3, 3))
2236: (4)             >>> yarr
2237: (4)             array([[0.45038594, 0.37079802, 0.92676499],
2238: (11)                 [0.64386512, 0.82276161, 0.4434142 ],
2239: (11)                 [0.22723872, 0.55458479, 0.06381726]])
2240: (4)             >>> R2 = np.corrcoef(xarr, yarr)
2241: (4)             >>> R2
2242: (4)             array([[ 1.          ,  0.99256089, -0.68080986,  0.75008178, -0.934284 ,
2243: (12)                 -0.99004057],
2244: (11)                 [ 0.99256089,  1.          , -0.76492172,  0.82502011, -0.97074098,
2245: (12)                 -0.99981569],
2246: (11)                 [-0.68080986, -0.76492172,  1.          , -0.99507202,  0.89721355,
2247: (13)                 0.77714685],
2248: (11)                 [ 0.75008178,  0.82502011, -0.99507202,  1.          , -0.93657855,
2249: (12)                 -0.83571711],
2250: (11)                 [-0.934284 , -0.97074098,  0.89721355, -0.93657855,  1.          ,
2251: (13)                 0.97517215],
2252: (11)                 [-0.99004057, -0.99981569,  0.77714685, -0.83571711,  0.97517215,
2253: (13)                 1.          ]])
2254: (4)             Finally if we use the option ``rowvar=False``, the columns are now
2255: (4)             being treated as the variables and we will find the column-wise Pearson
2256: (4)             correlation coefficients between variables in ``xarr`` and ``yarr``.

"""
Return the Bartlett window.

The Bartlett window is very similar to a triangular window, except
that the end points are at zero. It is often used in signal
processing for tapering a signal, without generating too much
ripple in the frequency domain.

Parameters
-----
M : int
    Number of points in the output window. If zero or less, an
    empty array is returned.

Returns
-----
out : array
    The triangular window, with the maximum value normalized to one
    (the value one appears only if the number of samples is odd), with
    the first and last samples equal to zero.

See Also
-----

```

proper ufunc written in C, and more than an order of magnitude faster. We use the algorithm published by Clenshaw [1] and referenced by Abramowitz and Stegun [2], for which the function domain is partitioned into the two intervals  $[0,8]$  and  $(8,\infty)$ , and Chebyshev polynomial expansions are employed in each interval. Relative error on the domain  $[0,30]$  using IEEE arithmetic is documented [3] as having a peak of  $5.8e-16$  with an rms of  $1.4e-16$  ( $n = 30000$ ).

def kaiser(M, beta):
    """
    Return the Kaiser window.

    The Kaiser window is a taper formed by using a Bessel function.

    Parameters
    -----
    M : int
        Number of points in the output window. If zero or less, an
        empty array is returned.
    beta : float
        Shape parameter for window.

    Returns
    -----
    out : array
        The window, with the maximum value normalized to one (the value
        one appears only if the number of samples is odd).
    See Also
    -----
    bartlett, blackman, hamming, hanning
    Notes
    -----
    The Kaiser window is defined as
    .. math:: w(n) = I_0 \left( \beta \sqrt{1 - \frac{4n^2}{(M-1)^2}} \right) / I_0(\beta)
    with
    .. math:: \quad -\frac{M-1}{2} \leq n \leq \frac{M-1}{2},
    where :math:`I_0` is the modified zeroth-order Bessel function.
    The Kaiser was named for Jim Kaiser, who discovered a simple
    approximation to the DPSS window based on Bessel functions. The Kaiser
    window is a very good approximation to the Digital Prolate Spheroidal
    Sequence, or Slepian window, which is the transform which maximizes the
    energy in the main lobe of the window relative to total energy.
    The Kaiser can approximate many other windows by varying the beta
    parameter.

2880: (4)                 Return the normalized sinc function.
2881: (4)                 The sinc function is equal to :math:`\sin(\pi x)/(\pi x)` for any argument
2882: (4)                 :math:`x \neq 0` . ``sinc(0)`` takes the limit value 1, making ``sinc`` not
2883: (4)                 only everywhere continuous but also infinitely differentiable.
2884: (4)                 .. note::
2885: (8)                     Note the normalization factor of ``pi`` used in the definition.
2886: (8)                     This is the most commonly used definition in signal processing.
2887: (8)                     Use ``sinc(x / np.pi)`` to obtain the unnormalized sinc function
2888: (8)                     :math:`\sin(x)/x` that is more common in mathematics.
2889: (4)             Parameters
2890: (4)             -----
2891: (4)             x : ndarray
2892: (8)                 Array (possibly multi-dimensional) of values for which to calculate
2893: (8)                 ``sinc(x)``.
2894: (4)             Returns
2895: (4)             -----
2896: (4)             out : ndarray
2897: (8)                 ``sinc(x)``, which has the same shape as the input.
2898: (4)             Notes
2899: (4)             -----
2900: (4)                 The name sinc is short for "sine cardinal" or "sinus cardinalis".
2901: (4)                 The sinc function is used in various signal processing applications,
2902: (4)                 including in anti-aliasing, in the construction of a Lanczos resampling
2903: (4)                 filter, and in interpolation.
2904: (4)                 For bandlimited interpolation of discrete-time signals, the ideal
2905: (4)                 interpolation kernel is proportional to the sinc function.

3052: (4)                 a : array_like
3053: (8)                     Input array or object that can be converted to an array.
3054: (4)                 axis : {int, sequence of int, None}, optional
3055: (8)                     Axis or axes along which the medians are computed. The default
3056: (8)                     is to compute the median along a flattened version of the array.
3057: (8)                     A sequence of axes is supported since version 1.9.0.
3058: (4)                 out : ndarray, optional
3059: (8)                     Alternative output array in which to place the result. It must
3060: (8)                     have the same shape and buffer length as the expected output,
3061: (8)                     but the type (of the output) will be cast if necessary.
3062: (4)                 overwrite_input : bool, optional
3063: (7)                     If True, then allow use of memory of input array `a` for
3064: (7)                     calculations. The input array will be modified by the call to
3065: (7)                     `median`. This will save memory when you do not need to preserve
3066: (7)                     the contents of the input array. Treat the input as undefined,
3067: (7)                     but it will probably be fully or partially sorted. Default is
3068: (7)                     False. If `overwrite_input` is ``True`` and `a` is not already an
3069: (7)                     `ndarray`, an error will be raised.
3070: (4)                 keepdims : bool, optional
3071: (8)                     If this is set to True, the axes which are reduced are left
3072: (8)                     in the result as dimensions with size one. With this option,
3073: (8)                     the result will broadcast correctly against the original `arr`.
3074: (8)                     .. versionadded:: 1.9.0
3075: (4)             Returns
3076: (4)             -----
3077: (4)             median : ndarray
3078: (8)                 A new array holding the result. If the input contains integers
3079: (8)                 or floats smaller than ``float64``, then the output data-type is
3080: (8)                 ``np.float64``. Otherwise, the data-type of the output is the

```

```

3081: (8)           same as that of the input. If `out` is specified, that array is
3082: (8)           returned instead.
3083: (4)           See Also
3084: (4)           -----
3085: (4)           mean, percentile
3086: (4)           Notes
3087: (4)           -----
3088: (4)           Given a vector ``V`` of length ``N``, the median of ``V`` is the
3089: (4)           middle value of a sorted copy of ``V``, ``V_sorted`` - i
3090: (4)           e., ``V_sorted[(N-1)/2]``, when ``N`` is odd, and the average of the
3091: (4)           two middle values of ``V_sorted`` when ``N`` is even.
3092: (4)           Examples
3093: (4)           -----
3094: (4)           >>> a = np.array([[10, 7, 4], [3, 2, 1]])

               *,
               interpolation=None):
    """
    Compute the q-th percentile of the data along the specified axis.
    Returns the q-th percentile(s) of the array elements.
    Parameters
    -----
    a : array_like of real numbers
        Input array or object that can be converted to an array.
    q : array_like of float
        Percentage or sequence of percentages for the percentiles to compute.
        Values must be between 0 and 100 inclusive.
    axis : {int, tuple of int, None}, optional
        Axis or axes along which the percentiles are computed. The
        default is to compute the percentile(s) along a flattened
        version of the array.
        .. versionchanged:: 1.9.0
            A tuple of axes is supported
    out : ndarray, optional
        Alternative output array in which to place the result. It must
        have the same shape and buffer length as the expected output,
        but the type (of the output) will be cast if necessary.
    overwrite_input : bool, optional
        If True, then allow the input array `a` to be modified by intermediate
        calculations, to save memory. In this case, the contents of the input
        `a` after this function completes is undefined.
    method : str, optional
        This parameter specifies the method to use for estimating the
        percentile. There are many different methods, some unique to NumPy.
        See the notes for explanation. The options sorted by their R type
        as summarized in the H&F paper [1]_ are:
        1. 'inverted_cdf'
        2. 'averaged_inverted_cdf'
        3. 'closest_observation'
        4. 'interpolated_inverted_cdf'
        5. 'hazen'
        6. 'weibull'
        7. 'linear' (default)
        8. 'median_unbiased'
        9. 'normal_unbiased'
        The first three methods are discontinuous. NumPy further defines the
        following discontinuous variations of the default 'linear' (7.).
        *
        * 'lower'
        * 'higher',
        * 'midpoint'
        * 'nearest'
        .. versionchanged:: 1.22.0
            This argument was previously called "interpolation" and only

```

```

3218: (12) offered the "linear" default and last four options.
3219: (4) keepdims : bool, optional
3220: (8) If this is set to True, the axes which are reduced are left in
3221: (8) the result as dimensions with size one. With this option, the
3222: (8) result will broadcast correctly against the original array `a`.
3223: (8) .. versionadded:: 1.9.0
3224: (4) interpolation : str, optional
3225: (8) Deprecated name for the method keyword argument.
3226: (8) .. deprecated:: 1.22.0
3227: (4) Returns
3228: (4)
3229: (4) -----
3230: (8) percentile : scalar or ndarray
3231: (8) If `q` is a single percentile and `axis=None`, then the result
3232: (8) is a scalar. If multiple percentiles are given, first axis of
3233: (8) the result corresponds to the percentiles. The other axes are
3234: (8) the axes that remain after the reduction of `a`. If the input
3235: (8) contains integers or floats smaller than ``float64``, the output
3236: (8) data-type is ``float64``. Otherwise, the output data-type is the
3237: (8) same as that of the input. If `out` is specified, that array is
3238: (4) returned instead.
3239: (4) See Also
3240: (4) -----
3241: (4) mean
3242: (4) median : equivalent to ``percentile(..., 50)``
3243: (4) nanpercentile
3244: (4) quantile : equivalent to percentile, except q in the range [0, 1].
3245: (4) Notes
3246: (4) -----
3247: (4) Given a vector ``V`` of length ``n``, the q-th percentile of ``V`` is
3248: (4) the value ``q/100`` of the way from the minimum to the maximum in a
3249: (4) sorted copy of ``V``. The values and distances of the two nearest
3250: (4) neighbors as well as the `method` parameter will determine the
3251: (4) percentile if the normalized ranking does not match the location of
3252: (4) ``q`` exactly. This function is the same as the median if ``q=50``, the
3253: (4) same as the minimum if ``q=0`` and the same as the maximum if
3254: (4) ``q=100``.
3255: (4) The optional `method` parameter specifies the method to use when the
3256: (4) desired percentile lies between two indexes ``i`` and ``j = i + 1``.
3257: (4) In that case, we first determine ``i + g``, a virtual index that lies
3258: (4) between ``i`` and ``j``, where ``i`` is the floor and ``g`` is the
3259: (4) fractional part of the index. The final result is, then, an interpolation
3260: (4) of ``a[i]`` and ``a[j]`` based on ``g``. During the computation of ``g``,
3261: (4) ``i`` and ``j`` are modified using correction constants ``alpha`` and
3262: (4) ``beta`` whose choices depend on the ``method`` used. Finally, note that
3263: (4) since Python uses 0-based indexing, the code subtracts another 1 from the
3264: (4) index internally.
3265: (4) The following formula determines the virtual index ``i + g``, the location
3266: (4) of the percentile in the sorted sample:
3267: (8) .. math::
3268: (8)     i + g = (q / 100) * (n - alpha - beta + 1) + alpha
3269: (4) The different methods then work as follows
3270: (8) inverted_cdf:
3271: (8)     method 1 of H&F [1]_.
3272: (8)     This method gives discontinuous results:
3273: (8)     * if g > 0 ; then take j
3274: (8)     * if g = 0 ; then take i
3275: (8) averaged_inverted_cdf:
3276: (8)     method 2 of H&F [1]_.
3277: (8)     This method give discontinuous results:
3278: (8)     * if g > 0 ; then take j
3279: (4)     * if g = 0 ; then average between bounds
3280: (8) closest_observation:
3281: (8)     method 3 of H&F [1]_.
3282: (8)     This method give discontinuous results:
3283: (8)     * if g > 0 ; then take j
3284: (8)     * if g = 0 and index is odd ; then take j
3285: (4)     * if g = 0 and index is even ; then take i
3286: (8) interpolated_inverted_cdf:
3287: (8)     method 4 of H&F [1]_.

```

3424: (8)                               Probability or sequence of probabilities for the quantiles to compute.
3425: (8)                               Values must be between 0 and 1 inclusive.
3426: (4)                               axis : {int, tuple of int, None}, optional
3427: (8)                               Axis or axes along which the quantiles are computed. The default is
3428: (8)                               to compute the quantile(s) along a flattened version of the array.
3429: (4)                               out : ndarray, optional
3430: (8)                               Alternative output array in which to place the result. It must have
3431: (8)                               the same shape and buffer length as the expected output, but the
3432: (8)                               type (of the output) will be cast if necessary.
3433: (4)                               overwrite_input : bool, optional
3434: (8)                               If True, then allow the input array `a` to be modified by
3435: (8)                               intermediate calculations, to save memory. In this case, the
3436: (8)                               contents of the input `a` after this function completes is
3437: (8)                               undefined.
3438: (4)                               method : str, optional
3439: (8)                               This parameter specifies the method to use for estimating the
3440: (8)                               quantile. There are many different methods, some unique to NumPy.
3441: (8)                               See the notes for explanation. The options sorted by their R type
3442: (8)                               as summarized in the H&F paper [1]_ are:
3443: (8)                               1. 'inverted_cdf'
3444: (8)                               2. 'averaged_inverted_cdf'
3445: (8)                               3. 'closest_observation'
3446: (8)                               4. 'interpolated_inverted_cdf'
3447: (8)                               5. 'hazen'
3448: (8)                               6. 'weibull'
3449: (8)                               7. 'linear' (default)
3450: (8)                               8. 'median_unbiased'
3451: (8)                               9. 'normal_unbiased'
3452: (8)                               The first three methods are discontinuous. NumPy further defines the
3453: (8)                               following discontinuous variations of the default 'linear' (7.)
option:
3454: (8)                               * 'lower'
3455: (8)                               * 'higher',
3456: (8)                               * 'midpoint'
3457: (8)                               * 'nearest'
3458: (8)                               .. versionchanged:: 1.22.0
3459: (12)                              This argument was previously called "interpolation" and only
3460: (12)                              offered the "linear" default and last four options.
keepdims : bool, optional
3461: (4)                               If this is set to True, the axes which are reduced are left in
3462: (8)                               the result as dimensions with size one. With this option, the
3463: (8)                               result will broadcast correctly against the original array `a`.
3464: (8)                               interpolation : str, optional
3465: (4)                               Deprecated name for the method keyword argument.
3466: (8)                               .. deprecated:: 1.22.0
3467: (8)                               Returns
3468: (4)                               -----
3469: (4)                               quantile : scalar or ndarray
3470: (4)                               If `q` is a single probability and `axis=None`, then the result
3471: (8)                               is a scalar. If multiple probabilities levels are given, first axis of
3472: (8)                               the result corresponds to the quantiles. The other axes are
3473: (8)                               the axes that remain after the reduction of `a`. If the input
3474: (8)                               contains integers or floats smaller than ``float64``, the output
3475: (8)                               data-type is ``float64``. Otherwise, the output data-type is the
3476: (8)                               same as that of the input. If `out` is specified, that array is
3477: (8)                               returned instead.
3478: (8)                               See Also
3479: (4)                               -----
3480: (4)                               mean
3481: (4)                               percentile : equivalent to quantile, but with q in the range [0, 100].
3482: (4)                               median : equivalent to ``quantile(..., 0.5)``
3483: (4)                               nanquantile
3484: (4)                               Notes
3485: (4)                               -----
3486: (4)                               Given a vector ``V`` of length ``n``, the q-th quantile of ``V`` is
3487: (4)                               the value ``q`` of the way from the minimum to the maximum in a
3488: (4)                               sorted copy of ``V``. The values and distances of the two nearest
3489: (4)                               neighbors as well as the `method` parameter will determine the
3490: (4)                               quantile if the normalized ranking does not match the location of
3491: (4)

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

3492: (4)           ``q`` exactly. This function is the same as the median if ``q=0.5``, the
3493: (4)           same as the minimum if ``q=0.0`` and the same as the maximum if
3494: (4)           ``q=1.0``.
3495: (4)           The optional `method` parameter specifies the method to use when the
3496: (4)           desired quantile lies between two indexes ``i`` and ``j = i + 1``.
3497: (4)           In that case, we first determine ``i + g``, a virtual index that lies
3498: (4)           between ``i`` and ``j``, where ``i`` is the floor and ``g`` is the
3499: (4)           fractional part of the index. The final result is, then, an interpolation
3500: (4)           of ``a[i]`` and ``a[j]`` based on ``g``. During the computation of ``g``,
3501: (4)           ``i`` and ``j`` are modified using correction constants ``alpha`` and
3502: (4)           ``beta`` whose choices depend on the ``method`` used. Finally, note that
3503: (4)           since Python uses 0-based indexing, the code subtracts another 1 from the
3504: (4)           index internally.
3505: (4)           The following formula determines the virtual index ``i + g``, the location
3506: (4)           of the quantile in the sorted sample:
3507: (4)           .. math::
3508: (8)              $i + g = q * (n - \alpha - \beta + 1) + \alpha$ 
3509: (4)           The different methods then work as follows
3510: (4)           inverted_cdf:
3511: (8)             method 1 of H&F [1]..
3512: (8)             This method gives discontinuous results:
3513: (8)               * if  $g > 0$ ; then take  $j$ 
3514: (8)               * if  $g = 0$ ; then take  $i$ 
3515: (4)           averaged_inverted_cdf:
3516: (8)             method 2 of H&F [1]..
3517: (8)             This method gives discontinuous results:
3518: (8)               * if  $g > 0$ ; then take  $j$ 
3519: (8)               * if  $g = 0$ ; then average between bounds
3520: (4)           closest_observation:
3521: (8)             method 3 of H&F [1]..
3522: (8)             This method gives discontinuous results:
3523: (8)               * if  $g > 0$ ; then take  $j$ 
3524: (8)               * if  $g = 0$  and index is odd; then take  $j$ 
3525: (8)               * if  $g = 0$  and index is even; then take  $i$ 
3526: (4)           interpolated_inverted_cdf:
3527: (8)             method 4 of H&F [1]..
3528: (8)             This method gives continuous results using:
3529: (8)               *  $\alpha = 0$ 
3530: (8)               *  $\beta = 1$ 
3531: (4)           hazen:
3532: (8)             method 5 of H&F [1]..
3533: (8)             This method gives continuous results using:

    """
    Integrate along the given axis using the composite trapezoidal rule.
    If `x` is provided, the integration happens in sequence along its
    elements - they are not sorted.
    Integrate `y` (`x`) along each 1d slice on the given axis, compute
    :math:`\int y(x) dx`.
    When `x` is specified, this integrates along the parametric curve,
    computing :math:`\int_t y(t) dt =
    \int_t y(t) \left.\frac{dx}{dt}\right|_{x=x(t)} dt`.
    Parameters
    -----
    y : array_like
        Input array to integrate.
    x : array_like, optional
        The sample points corresponding to the `y` values. If `x` is None,
        the sample points are assumed to be evenly spaced `dx` apart. The
        default is None.
    dx : scalar, optional
        The spacing between sample points when `x` is None. The default is 1.
    axis : int, optional
        The axis along which to integrate.
    Returns
    -----
    trapz : float or ndarray
        Definite integral of `y` = n-dimensional array as approximated along
        a single axis by the trapezoidal rule. If `y` is a 1-dimensional
        then the result is a float. If `n` is greater than 1, then the result
        is an `n`-1 dimensional array.
    See Also
    -----
    sum, cumsum
    Notes
    -----
    Image [2]_ illustrates trapezoidal rule -- y-axis locations of points
    will be taken from `y` array, by default x-axis distances between
    points will be 1.0, alternatively they can be provided with `x` array
    or with `dx` scalar. Return value will be equal to combined area under
    the red lines.

```

```

3907: (11)
https://en.wikipedia.org/wiki/File:Composite\_trapezoidal\_rule\_illustration.png
3908: (4)             Examples
3909: (4)
3910: (4)             -----
3911: (4)             Use the trapezoidal rule on evenly spaced points:
3912: (4)             >>> np.trapz([1, 2, 3])
3913: (4)             4.0
3914: (4)             The spacing between sample points can be selected by either the
3915: (4)             ``x`` or ``dx`` arguments:
3916: (4)             >>> np.trapz([1, 2, 3], x=[4, 6, 8])
3917: (4)             8.0
3918: (4)             >>> np.trapz([1, 2, 3], dx=2)
3919: (4)             8.0
3920: (4)             Using a decreasing ``x`` corresponds to integrating in reverse:
3921: (4)             >>> np.trapz([1, 2, 3], x=[8, 6, 4])
3922: (4)             -8.0
3923: (4)             More generally ``x`` is used to integrate along a parametric curve. We can
3924: (4)             estimate the integral :math:`\int_0^1 x^2 = 1/3` using:
3925: (4)             >>> x = np.linspace(0, 1, num=50)
3926: (4)             >>> y = x**2
3927: (4)             0.33340274885464394
3928: (4)             Or estimate the area of a circle, noting we repeat the sample which closes
3929: (4)             the curve:
3930: (4)             >>> theta = np.linspace(0, 2 * np.pi, num=1000, endpoint=True)
3931: (4)             >>> np.trapz(np.cos(theta), x=np.sin(theta))
3932: (4)             3.141571941375841
3933: (4)             ``np.trapz`` can be applied along a specified axis to do multiple
3934: (4)             computations in one call:
3935: (4)             >>> a = np.arange(6).reshape(2, 3)
3936: (4)
3937: (4)             >>> a
3938: (11)            array([[0, 1, 2],
3939: (4)                         [3, 4, 5]])
3940: (4)             >>> np.trapz(a, axis=0)
3941: (4)             array([1.5, 2.5, 3.5])
3942: (4)             >>> np.trapz(a, axis=1)
3943: (4)             array([2., 8.])

def _meshgrid_dispatcher(*xi, copy=None, sparse=None, indexing=None):
    return xi
@array_function_dispatch(_meshgrid_dispatcher)
def meshgrid(*xi, copy=True, sparse=False, indexing='xy'):
    """
        Return a list of coordinate matrices from coordinate vectors.
        Make N-D coordinate arrays for vectorized evaluations of
        N-D scalar/vector fields over N-D grids, given
        one-dimensional coordinate arrays x1, x2,..., xn.
        .. versionchanged:: 1.9
            1-D and 0-D cases are allowed.
    Parameters
    -----
    x1, x2,..., xn : array_like
        1-D arrays representing the coordinates of a grid.
    indexing : {'xy', 'ij'}, optional
        Cartesian ('xy', default) or matrix ('ij') indexing of output.
        See Notes for more details.
        .. versionadded:: 1.7.0
    sparse : bool, optional
        If True the shape of the returned coordinate array for dimension *i*
        is reduced from ``(N1, ..., Ni, ... Nn)`` to
        ``(1, ..., 1, Ni, 1, ..., 1)``. These sparse coordinate grids are
        intended to be used with :ref:`basics.broadcasting`. When all
        coordinates are used in an expression, broadcasting still leads to a
        fully-dimensional result array.
        Default is False.
        .. versionadded:: 1.7.0
    copy : bool, optional
        If False, a view into the original arrays are returned in order to
        conserve memory. Default is True. Please note that
        ``sparse=False, copy=False`` will likely return non-contiguous
        arrays. Furthermore, more than one element of a broadcast array
        may refer to a single memory location. If you need to write to the
        arrays, make copies first.
        .. versionadded:: 1.7.0
    Returns
    -----
    X1, X2,..., XN : list of ndarrays
        For vectors `x1`, `x2`,..., `xn` with lengths ``Ni=len(xi)``,
        returns ``(N1, N2, N3,..., Nn)`` shaped arrays if indexing='ij'
        or ``(N2, N1, N3,..., Nn)`` shaped arrays if indexing='xy'
        with the elements of `xi` repeated to fill the matrix along
        the first dimension for `x1`, the second for `x2` and so on.
    Notes
    -----
    This function supports both indexing conventions through the indexing
    keyword argument. Giving the string 'ij' returns a meshgrid with
    matrix indexing, while 'xy' returns a meshgrid with Cartesian indexing.
    In the 2-D case with inputs of length M and N, the outputs are of shape
    (N, M) for 'xy' indexing and (M, N) for 'ij' indexing. In the 3-D case
    with inputs of length M, N and P, outputs are of shape (N, M, P) for
    'xy' indexing and (M, N, P) for 'ij' indexing. The difference is
    illustrated by the following code snippet::
        xv, yv = np.meshgrid(x, y, indexing='ij')
        for i in range(nx):
            for j in range(ny):
                xv, yv = np.meshgrid(x, y, indexing='xy')
                for i in range(nx):
                    for j in range(ny):
    In the 1-D and 0-D case, the indexing and sparse keywords have no effect.

4108: (4)     def delete(arr, obj, axis=None):
4108: (4)         """
4108: (4)             Return a new array with sub-arrays along an axis deleted. For a one

```

```

4109: (4) dimensional array, this returns those entries not returned by
4110: (4) `arr[obj]`.
4111: (4) Parameters
4112: (4) -----
4113: (4) arr : array_like
4114: (8) Input array.
4115: (4) obj : slice, int or array of ints
4116: (8) Indicate indices of sub-arrays to remove along the specified axis.
4117: (8) .. versionchanged:: 1.19.0
4118: (12) Boolean indices are now treated as a mask of elements to remove,
4119: (12) rather than being cast to the integers 0 and 1.
4120: (4) axis : int, optional
4121: (8) The axis along which to delete the subarray defined by `obj`.
4122: (8) If `axis` is None, `obj` is applied to the flattened array.
4123: (4) Returns
4124: (4) -----
4125: (4) out : ndarray
4126: (8) A copy of `arr` with the elements specified by `obj` removed. Note
4127: (8) that `delete` does not occur in-place. If `axis` is None, `out` is
4128: (8) a flattened array.
4129: (4) See Also
4130: (4) -----
4131: (4) insert : Insert elements into an array.
4132: (4) append : Append elements at the end of an array.
4133: (4) Notes
4134: (4) -----
4135: (4) Often it is preferable to use a boolean mask. For example:
4136: (4) >>> arr = np.arange(12) + 1
4137: (4) >>> mask = np.ones(len(arr), dtype=bool)
4138: (4) >>> mask[[0,2,4]] = False
4139: (4) >>> result = arr[mask,...]
4140: (4) Is equivalent to ``np.delete(arr, [0,2,4], axis=0)``, but allows further
4141: (4) use of `mask`.
4142: (4) Examples
4143: (4) -----
4144: (4) >>> arr = np.array([[1,2,3,4], [5,6,7,8], [9,10,11,12]])
4145: (4) >>> arr
4146: (4) array([[ 1,  2,  3,  4],
4147: (11)      [ 5,  6,  7,  8],
4148: (11)      [ 9, 10, 11, 12]])
4149: (4) >>> np.delete(arr, 1, 0)
4150: (4) array([[ 1,  2,  3,  4],
4151: (11)      [ 9, 10, 11, 12]])
4152: (4) >>> np.delete(arr, np.s_[:2], 1)
4153: (4) array([[ 2,  4],
4154: (11)      [ 6,  8],
4155: (11)      [10, 12]])
4156: (4) >>> np.delete(arr, [1,3,5], None)

4500: (4)          ValueError
4501: (8)              If `bins` is not monotonic.
4502: (4)          TypeError
4503: (8)              If the type of the input is complex.
4504: (4)          See Also
4505: (4)          -----
4506: (4)          bincount, histogram, unique, searchsorted
4507: (4)          Notes
4508: (4)          -----
4509: (4)          If values in `x` are such that they fall outside the bin range,
4510: (4)          attempting to index `bins` with the indices that `digitize` returns
4511: (4)          will result in an IndexError.
4512: (4)          .. versionadded:: 1.10.0
4513: (4)          `np.digitize` is implemented in terms of `np.searchsorted`. This means
4514: (4)          that a binary search is used to bin the values, which scales much better
4515: (4)          for larger number of bins than the previous linear search. It also removes
4516: (4)          the requirement for the input array to be 1-dimensional.
4517: (4)          For monotonically _increasing_ `bins`, the following are equivalent::
4518: (8)              np.digitize(x, bins, right=True)
4519: (8)              np.searchsorted(bins, x, side='left')
4520: (4)          Note that as the order of the arguments are reversed, the side must be
        too.
4521: (4)          The `searchsorted` call is marginally faster, as it does not do any

```

```

4522: (4)    monotonicity checks. Perhaps more importantly, it supports all dtypes.
4523: (4)    Examples
4524: (4)
4525: (4)    -----
4526: (4)    >>> x = np.array([0.2, 6.4, 3.0, 1.6])

173: (4)      iqr = np.subtract(*np.percentile(x, [75, 25]))
174: (4)      return 2.0 * iqr * x.size ** (-1.0 / 3.0)
175: (0)      def _hist_bin_auto(x, range):
176: (4)      """
177: (4)      Histogram bin estimator that uses the minimum width of the
178: (4)      Freedman-Diaconis and Sturges estimators if the FD bin width is non-zero.
179: (4)      If the bin width from the FD estimator is 0, the Sturges estimator is
used.
180: (4)      The FD estimator is usually the most robust method, but its width
181: (4)      estimate tends to be too large for small `x` and bad for data with limited
182: (4)      variance. The Sturges estimator is quite good for small (<1000) datasets
183: (4)      and is the default in the R language. This method gives good off-the-shelf
184: (4)      behaviour.
185: (4)      .. versionchanged:: 1.15.0
186: (4)      If there is limited variance the IQR can be 0, which results in the
187: (4)      FD bin width being 0 too. This is not a valid bin width, so
188: (4)      ``np.histogram_bin_edges`` chooses 1 bin instead, which may not be
optimal.
189: (4)      If the IQR is 0, it's unlikely any variance-based estimators will be of
190: (4)      use, so we revert to the Sturges estimator, which only uses the size of
the
191: (4)      dataset in its calculation.

392: (12)                                         Less robust estimator that takes into account data variability
393: (12)                                         and data size.
394: (8)                                         'stone'
395: (12)                                         Estimator based on leave-one-out cross-validation estimate of
396: (12)                                         the integrated squared error. Can be regarded as a generalization
397: (12)                                         of Scott's rule.
398: (8)                                         'rice'
399: (12)                                         Estimator does not take variability into account, only data
400: (12)                                         size. Commonly overestimates number of bins required.
401: (8)                                         'sturges'
402: (12)                                         R's default method, only accounts for data size. Only
403: (12)                                         optimal for gaussian data and underestimates number of bins
404: (12)                                         for large non-gaussian datasets.
405: (8)                                         'sqrt'
406: (12)                                         Square root (of data size) estimator, used by Excel and
407: (12)                                         other programs for its speed and simplicity.
408: (4)                                         range : (float, float), optional
409: (8)                                         The lower and upper range of the bins. If not provided, range
410: (8)                                         is simply ``a.min(), a.max()``. Values outside the range are
411: (8)                                         ignored. The first element of the range must be less than or
412: (8)                                         equal to the second. `range` affects the automatic bin
413: (8)                                         computation as well. While bin width is computed to be optimal
414: (8)                                         based on the actual data within `range`, the bin count will fill
415: (8)                                         the entire range including portions containing no data.
416: (4)                                         weights : array_like, optional
417: (8)                                         An array of weights, of the same shape as `a`. Each value in
418: (8)                                         `a` only contributes its associated weight towards the bin count
419: (8)                                         (instead of 1). This is currently not used by any of the bin
estimators,
420: (8)                                         but may be in the future.
421: (4)                                         Returns
422: (4)                                         -----
423: (4)                                         bin_edges : array of dtype float
424: (8)                                         The edges to pass into `histogram`
425: (4)                                         See Also

427: (4)                                         histogram
428: (4)                                         Notes
429: (4)                                         -----
430: (4)                                         The methods to estimate the optimal number of bins are well founded

```

```

431: (4) in literature, and are inspired by the choices R provides for
432: (4) histogram visualisation. Note that having the number of bins
433: (4) proportional to :math:`n^{1/3}` is asymptotically optimal, which is
434: (4) why it appears in most estimators. These are simply plug-in methods
435: (4) that give good starting points for number of bins. In the equations
436: (4) below, :math:`h` is the binwidth and :math:`n_h` is the number of
437: (4) bins. All estimators that compute bin counts are recast to bin width
438: (4) using the `ptp` of the data. The final bin count is obtained from
439: (4) ``np.round(np.ceil(range / h))``. The final bin width is often less
440: (4) than what is returned by the estimators below.
441: (4) 'auto' (maximum of the 'sturges' and 'fd' estimators)
442: (8) A compromise to get a good value. For small datasets the Sturges
443: (8) value will usually be chosen, while larger datasets will usually
444: (8) default to FD. Avoids the overly conservative behaviour of FD
445: (8) and Sturges for small and large datasets respectively.
446: (8) Switchover point is usually :math:`a.size \approx 1000` .
447: (4) 'fd' (Freedman Diaconis Estimator)
448: (8) .. math:: h = 2 \frac{IQR}{n^{1/3}}
449: (8) The binwidth is proportional to the interquartile range (IQR)
450: (8) and inversely proportional to cube root of a.size. Can be too
451: (8) conservative for small datasets, but is quite good for large
452: (8) datasets. The IQR is very robust to outliers.
453: (4) 'scott'
454: (8) .. math:: h = \sigma \sqrt[3]{\frac{24}{\pi} n}
455: (8) The binwidth is proportional to the standard deviation of the
456: (8) data and inversely proportional to cube root of ``x.size``. Can
457: (8) be too conservative for small datasets, but is quite good for
458: (8) large datasets. The standard deviation is not very robust to
459: (8) outliers. Values are very similar to the Freedman-Diaconis
460: (8) estimator in the absence of outliers.
461: (4) 'rice'
462: (8) .. math:: n_h = 2n^{1/3}
463: (8) The number of bins is only proportional to cube root of
464: (8) ``a.size``. It tends to overestimate the number of bins and it
465: (8) does not take into account data variability.
466: (4) 'sturges'
467: (8) .. math:: n_h = \log_2(n) + 1
468: (8) The number of bins is the base 2 log of ``a.size``. This
469: (8) estimator assumes normality of data and is too conservative for
470: (8) larger, non-normal datasets. This is the default method in R's
471: (8) ``hist`` method.
472: (4) 'doane'
473: (8) .. math:: n_h = 1 + \log_2(n) +
474: (24) \log_2(1 + \frac{|g_1|}{\sigma_{g_1}})
475: (12) g_1 = mean(x - \mu)^3
476: (12) \sigma_{g_1} = \sqrt{\frac{6(n-2)}{(n+1)(n+3)}}
477: (8) An improved version of Sturges' formula that produces better
478: (8) estimates for non-normal datasets. This estimator attempts to
479: (8) account for the skew of the data.
480: (4) 'sqrt'
481: (8) .. math:: n_h = \sqrt{n}
482: (8) The simplest and fastest estimator. Only takes into account the
483: (8) data size.
484: (4) Examples
485: (4) -----
486: (4) >>> arr = np.array([0, 0, 0, 1, 2, 3, 3, 4, 5])
487: (4) >>> np.histogram_bin_edges(arr, bins='auto', range=(0, 1))
488: (4) array([0. , 0.25, 0.5 , 0.75, 1. ])
489: (4) >>> np.histogram_bin_edges(arr, bins=2)
490: (4) array([0. , 2.5, 5. ])
491: (4) For consistency with histogram, an array of pre-computed bins is
492: (4) passed through unmodified:
493: (4) >>> np.histogram_bin_edges(arr, [1, 2])
494: (4) array([1, 2])
495: (4) This function allows one set of bins to be computed, and reused across
496: (4) multiple histograms:
497: (4) >>> shared_bins = np.histogram_bin_edges(arr, bins='auto')
498: (4) >>> shared_bins
499: (4) array([0., 1., 2., 3., 4., 5.])

    return (a, bins, weights)

@array_function_dispatch(_histogram_dispatcher)
def histogram(a, bins=10, range=None, density=None, weights=None):
    """
    Compute the histogram of a dataset.

    Parameters
    -----
    a : array_like
        Input data. The histogram is computed over the flattened array.
    bins : int or sequence of scalars or str, optional
        If `bins` is an int, it defines the number of equal-width
        bins in the given range (10, by default). If `bins` is a
        sequence, it defines a monotonically increasing array of bin edges,
        including the rightmost edge, allowing for non-uniform bin widths.
        .. versionadded:: 1.11.0
        If `bins` is a string, it defines the method used to calculate the
        optimal bin width, as defined by `histogram_bin_edges`.
    range : (float, float), optional
        The lower and upper range of the bins. If not provided, range
        is simply ``(a.min(), a.max())``. Values outside the range are
        ignored. The first element of the range must be less than or
        equal to the second. `range` affects the automatic bin
        computation as well. While bin width is computed to be optimal
        based on the actual data within `range`, the bin count will fill
        the entire range including portions containing no data.
    weights : array_like, optional
        An array of weights, of the same shape as `a`. Each value in
        `a` only contributes its associated weight towards the bin count
        (instead of 1). If `density` is True, the weights are
        normalized, so that the integral of the density over the range
        remains 1.
    density : bool, optional
        If ``False``, the result will contain the number of samples in
        each bin. If ``True``, the result is the value of the
        probability *density* function at the bin, normalized such that
        the *integral* over the range is 1. Note that the sum of the
        histogram values will not be equal to 1 unless bins of unity
        width are chosen; it is not a probability *mass* function.

    Returns
    -----
    hist : array
        The values of the histogram. See `density` and `weights` for a
        description of the possible semantics.
    bin_edges : array of dtype float
        Return the bin edges ``length(hist)+1``.
    See Also
    -----

689: (4)             -----
690: (4)             sample : (N, D) array, or (N, D) array_like
691: (8)                 The data to be histogrammed.
692: (8)                 Note the unusual interpretation of sample when an array_like:
693: (8)
694: (10)                 * When an array, each row is a coordinate in a D-dimensional space -
695: (8)                     such as ``histogramdd(np.array([p1, p2, p3]))``.
696: (10)                 * When an array_like, each element is the list of values for single
697: (8)                     coordinate - such as ``histogramdd((X, Y, Z))``.
698: (4)                 The first form should be preferred.
699: (8)             bins : sequence or int, optional
700: (8)                 The bin specification:
701: (10)                 * A sequence of arrays describing the monotonically increasing bin
702: (8)                     edges along each dimension.
703: (8)                 * The number of bins for each dimension (nx, ny, ... =bins)
704: (8)                 * The number of bins for all dimensions (nx=ny=...=bins).
705: (4)             range : sequence, optional
706: (8)                 A sequence of length D, each an optional (lower, upper) tuple giving

```

the outer bin edges to be used if the edges are not given explicitly

```

in
707: (8)           `bins`.
708: (8)           An entry of None in the sequence results in the minimum and maximum
709: (8)           values being used for the corresponding dimension.
710: (8)           The default, None, is equivalent to passing a tuple of D None values.
711: (4)           density : bool, optional
712: (8)           If False, the default, returns the number of samples in each bin.
713: (8)           If True, returns the probability *density* function at the bin,
714: (8)           ``bin_count / sample_count / bin_volume``.
715: (4)           weights : (N,) array_like, optional
716: (8)           An array of values `w_i` weighing each sample `(x_i, y_i, z_i, ...)`.
717: (8)           Weights are normalized to 1 if density is True. If density is False,
718: (8)           the values of the returned histogram are equal to the sum of the
719: (8)           weights belonging to the samples falling into each bin.

27: (4)                Construct an open mesh from multiple sequences.
28: (4)                This function takes N 1-D sequences and returns N outputs with N
dimensions each, such that the shape is 1 in all but one dimension
and the dimension with the non-unit shape value cycles through all
30: (4)            """

```

```

31: (4)           N dimensions.
32: (4)           Using `ix_` one can quickly construct index arrays that will index
33: (4)           the cross product. ``a[np.ix_([1,3],[2,5])]`` returns the array
34: (4)           ``[[a[1,2] a[1,5]], [a[3,2] a[3,5]]]``.
35: (4)           Parameters
36: (4)           -----
37: (4)           args : 1-D sequences
38: (8)             Each sequence should be of integer or boolean type.
39: (8)             Boolean sequences will be interpreted as boolean masks for the
40: (8)             corresponding dimension (equivalent to passing in
41: (8)             ``np.nonzero(boolean_sequence)``).
42: (4)           Returns
43: (4)           -----
44: (4)           out : tuple of ndarrays
45: (8)             N arrays with N dimensions each, with N the number of input
46: (8)             sequences. Together these arrays form an open mesh.

class RClass(AxisConcatenator):
    """
    Translates slice objects to concatenation along the first axis.
    This is a simple way to build up arrays quickly. There are two use cases.
    1. If the index expression contains comma separated arrays, then stack
       them along their first axis.
    2. If the index expression contains slice notation or scalars then create
       a 1-D array with a range indicated by the slice notation.
    If slice notation is used, the syntax ``start:stop:step`` is equivalent
    to ``np.arange(start, stop, step)`` inside of the brackets. However, if
    ``step`` is an imaginary number (i.e. 100j) then its integer portion is
    interpreted as a number-of-points desired and the start and stop are
    inclusive. In other words ``start:stop:stepj`` is interpreted as
    ``np.linspace(start, stop, step, endpoint=1)`` inside of the brackets.
    After expansion of slice notation, all comma separated sequences are
    concatenated together.
    Optional character strings placed as the first element of the index
    expression can be used to change the output. The strings 'r' or 'c' result
    in matrix output. If the result is 1-D and 'r' is specified a 1 x N (row)
    matrix is produced. If the result is 1-D and 'c' is specified, then a N x
    (column) matrix is produced. If the result is 2-D then both provide the
    same matrix result.
    """

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

375: (4) A string integer specifies which axis to stack multiple comma separated
376: (4) arrays along. A string of two comma-separated integers allows indication
377: (4) of the minimum number of dimensions to force each entry into as the
378: (4) second integer (the axis to concatenate along is still the first integer).
379: (4) A string with three comma-separated integers allows specification of the
380: (4) axis to concatenate along, the minimum number of dimensions to force the
381: (4) entries to, and which axis should contain the start of the arrays which
382: (4) are less than the specified number of dimensions. In other words the third
383: (4) integer allows you to specify where the 1's should be placed in the shape
384: (4) of the arrays that have their shapes upgraded. By default, they are placed
385: (4) in the front of the shape tuple. The third argument allows you to specify
386: (4) where the start of the array should be instead. Thus, a third argument of
387: (4) '0' would place the 1's at the end of the array shape. Negative integers
388: (4) specify where in the new shape tuple the last dimension of upgraded arrays
389: (4) should be placed, so the default is '-1'.
390: (4) Parameters
391: (4) -----
392: (4) Not a function, so takes no parameters
393: (4) Returns
394: (4) -----
395: (4) A concatenated ndarray or matrix.

564: (4)               A nicer way to build up index tuples for arrays.
565: (4)               .. note::
566: (7)                 Use one of the two predefined instances `index_exp` or `s_`
567: (7)                 rather than directly using `IndexExpression`.
568: (4)               For any index combination, including slicing and axis insertion,
569: (4)               ``a[indices]`` is the same as ``a[np.index_exp[indices]]`` for any
570: (4)               array `a`. However, ``np.index_exp[indices]`` can be used anywhere
571: (4)               in Python code and returns a tuple of slice objects that can be
572: (4)               used in the construction of complex index expressions.
573: (4)               Parameters
574: (4)               -----
575: (4)               maketuple : bool
576: (8)                 If True, always returns a tuple.
577: (4)               See Also
578: (4)               -----
579: (4)               index_exp : Predefined instance that always returns a tuple:
580: (7)                 `index_exp = IndexExpression(maketuple=True)` .
581: (4)               s_ : Predefined instance without tuple conversion:

```

```

582: (7)           `s_ = IndexExpression(maketuple=False)` .
583: (4)           Notes
584: (4)
585: (4)           -----
586: (4)           You can do all this with `slice()` plus a few special objects,
587: (4)           but there's a lot to remember and this version is simpler because
588: (4)           it uses the standard array indexing syntax.
589: (4)           Examples
590: (4)           -----

612: (4)             For an array `a` with ``a.ndim >= 2``, the diagonal is the list of
613: (4)             locations with indices ``a[i, ..., i]`` all identical. This function
614: (4)             modifies the input array in-place, it does not return a value.
615: (4)             Parameters
616: (4)             -----
617: (6)               a : array, at least 2-D.
618: (4)               Array whose diagonal is to be filled, it gets modified in-place.
619: (6)               val : scalar or array_like
620: (6)               Value(s) to write on the diagonal. If `val` is scalar, the value is
621: (6)               written along the diagonal. If array-like, the flattened `val` is
622: (6)               written along the diagonal, repeating if necessary to fill all
623: (4)               diagonal entries.
624: (6)               wrap : bool
625: (6)               For tall matrices in NumPy version up to 1.6.2, the
626: (6)               diagonal "wrapped" after N columns. You can have this behavior
627: (4)               with this option. This affects only tall matrices.
628: (4)           See also
629: (4)           -----
630: (4)           diag_indices, diag_indices_from
631: (4)           Notes
632: (4)           -----
633: (4)           .. versionadded:: 1.4.0
634: (4)           This functionality can be obtained via `diag_indices`, but internally
635: (4)           this version uses a much faster implementation that never constructs the
636: (4)           indices and uses simple slicing.
637: (4)           Examples
638: (4)           -----
639: (4)           >>> a = np.zeros((3, 3), int)
640: (4)           >>> np.fill_diagonal(a, 5)
641: (4)           >>> a
642: (11)          array([[5, 0, 0],
643: (11)                      [0, 5, 0],
644: (4)                      [0, 0, 5]])
645: (4)           The same function can operate on a 4-D array:
646: (4)           >>> a = np.zeros((3, 3, 3, 3), int)
647: (4)           >>> np.fill_diagonal(a, 4)
648: (4)           We only show a few blocks for clarity:
649: (4)           >>> a[0, 0]
650: (11)          array([[4, 0, 0],
651: (11)                      [0, 0, 0],
652: (11)                      [0, 0, 0]])

```

```

651: (11)          [0, 0, 0]])]
652: (4)          >>> a[1, 1]
653: (4)          array([[0, 0, 0],
654: (11)          [0, 4, 0],
655: (11)          [0, 0, 0]])
656: (4)          >>> a[2, 2]
657: (4)          array([[0, 0, 0],
658: (11)          [0, 0, 0],
659: (11)          [0, 0, 4]])
660: (4)          The wrap option affects only tall matrices:
661: (4)          >>> # tall matrices no wrap
662: (4)          >>> a = np.zeros((5, 3), int)
663: (4)          >>> np.fill_diagonal(a, 4)
664: (4)          >>> a
665: (4)          array([[4, 0, 0],
666: (11)          [0, 4, 0],
667: (11)          [0, 0, 4],
668: (11)          [0, 0, 0],
669: (11)          [0, 0, 0]])
670: (4)          >>> # tall matrices wrap
671: (4)          >>> a = np.zeros((5, 3), int)
672: (4)          >>> np.fill_diagonal(a, 4, wrap=True)
673: (4)          >>> a
674: (4)          array([[4, 0, 0],
675: (11)          [0, 4, 0],
676: (11)          [0, 0, 4],
677: (11)          [0, 0, 0],
678: (11)          [4, 0, 0]])
679: (4)          >>> # wide matrices
680: (4)          >>> a = np.zeros((3, 5), int)
681: (4)          >>> np.fill_diagonal(a, 4, wrap=True)
682: (4)          >>> a
683: (4)          array([[4, 0, 0, 0, 0],
684: (11)          [0, 4, 0, 0, 0],
685: (11)          [0, 0, 4, 0, 0]])
686: (4)          The anti-diagonal can be filled by reversing the order of elements
687: (4)          using either `numpy.flipud` or `numpy.fliplr`.
688: (4)          >>> a = np.zeros((3, 3), int);
689: (4)          >>> np.fill_diagonal(np.fliplr(a), [1,2,3]) # Horizontal flip
690: (4)          >>> a
691: (4)          array([[0, 0, 1],
692: (11)          [0, 2, 0],
693: (11)          [3, 0, 0]])
694: (4)          >>> np.fill_diagonal(np.flipud(a), [1,2,3]) # Vertical flip
695: (4)          >>> a
696: (4)          array([[0, 0, 3],
697: (11)          [0, 2, 0],
698: (11)          [1, 0, 0]])
699: (4)          Note that the order in which the diagonal is filled varies depending
700: (4)          on the flip function.
701: (4)          """

734: (4)           -----
735: (4)           .. versionadded:: 1.4.0
736: (4)           Examples
737: (4)           -----
738: (4)           Create a set of indices to access the diagonal of a (4, 4) array:
739: (4)           >>> di = np.diag_indices(4)
740: (4)           >>> di
741: (4)           (array([0, 1, 2, 3]), array([0, 1, 2, 3]))
742: (4)           >>> a = np.arange(16).reshape(4, 4)
743: (4)           >>> a
744: (4)           array([[ 0,  1,  2,  3],
745: (11)             [ 4,  5,  6,  7],
746: (11)             [ 8,  9, 10, 11],
747: (11)             [12, 13, 14, 15]])
748: (4)           >>> a[di] = 100
749: (4)           >>> a
750: (4)           array([[100,  1,  2,  3],
751: (11)             [ 4, 100,  6,  7],
752: (11)             [ 8,  9, 100, 11],
753: (11)             [12, 13, 14, 100]])
754: (4)           Now, we create indices to manipulate a 3-D array:
755: (4)           >>> d3 = np.diag_indices(2, 3)
756: (4)           >>> d3
757: (4)           (array([0, 1]), array([0, 1]), array([0, 1]))
758: (4)           And use it to set the diagonal of an array of zeros to 1:
759: (4)           >>> a = np.zeros((2, 2, 2), dtype=int)
760: (4)           >>> a[d3] = 1
761: (4)           >>> a
762: (4)           array([[[1, 0],
763: (12)             [0, 0]],
764: (11)             [[0, 0],
765: (12)               [0, 1]]])
766: (4)           """
767: (4)           idx = np.arange(n)
768: (4)           return (idx,) * ndim
769: (0)           def _diag_indices_from(arr):
770: (4)               return (arr,)
771: (0)           @array_function_dispatch(_diag_indices_from)
772: (0)           def diag_indices_from(arr):
773: (4)               """
774: (4)               Return the indices to access the main diagonal of an n-dimensional array.
775: (4)               See `diag_indices` for full details.

class NDArryOperatorsMixin:
    """Mixin defining all operator special methods using __array_ufunc__.
    This class implements the special methods for almost all of Python's
    builtin operators defined in the `operator` module, including comparisons
    ('`==``', ``>``, etc.) and arithmetic ('`+``', ``*``', ``-``', etc.), by
    deferring to the ``__array_ufunc__`` method, which subclasses must
    implement.
    It is useful for writing classes that do not inherit from `numpy.ndarray`,
    but that should support arithmetic and numpy universal functions like
    arrays as described in `A Mechanism for Overriding Ufuncs
    <https://numpy.org/neps/nep-0013-ufunc-overrides.html>`.
    As an trivial example, consider this implementation of an ``ArrayLike```
    class that simply wraps a NumPy array and ensures that the result of any
    arithmetic operation is also an ``ArrayLike`` object::
        class ArrayLike(np.lib.mixins.NDArryOperatorsMixin):
            def __init__(self, value):
                self.value = np.asarray(value)
            _HANDLED_TYPES = (np.ndarray, numbers.Number)
            def __array_ufunc__(self, ufunc, method, *inputs, **kwargs):
                out = kwargs.get('out', ())
                for x in inputs + out:
                    if not isinstance(x, self._HANDLED_TYPES + (ArrayLike,)):
                        return NotImplemented
                    inputs = tuple(x.value if isinstance(x, ArrayLike) else x
                                  for x in inputs)
                if out:
                    kwargs['out'] = tuple(
                        x.value if isinstance(x, ArrayLike) else x
                        for x in out)
                result = getattr(ufunc, method)(*inputs, **kwargs)
                if type(result) is tuple:
                    return tuple(type(self)(x) for x in result)
                elif method == 'at':
                    return None
                else:
                    return type(self)(result)
            def __repr__(self):
                return '%s(%r)' % (type(self).__name__, self.value)
    In interactions between ``ArrayLike`` objects and numbers or numpy arrays,
    the result is always another ``ArrayLike``:
        >>> x = ArrayLike([1, 2, 3])
        >>> x - 1
        ArrayLike(array([0, 1, 2]))
        >>> 1 - x
        ArrayLike(array([ 0, -1, -2]))
        >>> np.arange(3) - x
        ArrayLike(array([-1, -1, -1]))
        >>> x - np.arange(3)
        ArrayLike(array([1, 1, 1]))
    Note that unlike ``numpy.ndarray``, ``ArrayLike`` does not allow
    with arbitrary, unrecognized types. This ensures that interactions with
    ArrayLike preserve a well-defined casting hierarchy.

           initial=np._NoValue, where=np._NoValue):
    """
    Return the product of array elements over a given axis treating Not a
    Numbers (NaNs) as ones.
    One is returned for slices that are all-NaN or empty.
    .. versionadded:: 1.10.0
    Parameters
    -----
    a : array_like
        Array containing numbers whose product is desired. If `a` is not an
        array, a conversion is attempted.
    axis : {int, tuple of int, None}, optional
        Axis or axes along which the product is computed. The default is to
        the product of the flattened array.
    dtype : data-type, optional
        The type of the returned array and of the accumulator in which the
        elements are summed. By default, the dtype of `a` is used. An
        exception is when `a` has an integer type with less precision than
        the platform (u)intp. In that case, the default will be either
        (u)int32 or (u)int64 depending on whether the platform is 32 or 64
        bits. For inexact inputs, dtype must be inexact.
    out : ndarray, optional
        Alternate output array in which to place the result. The default
        is ``None``. If provided, it must have the same shape as the
        expected output, but the type will be cast if necessary. See
        :ref:`ufuncs-output-type` for more details. The casting of NaN to
        can yield unexpected results.
    keepdims : bool, optional
        If True, the axes which are reduced are left in the result as
        dimensions with size one. With this option, the result will
        broadcast correctly against the original `arr`.
    initial : scalar, optional
        The starting value for this product. See `~numpy.ufunc.reduce`
        for details.
        .. versionadded:: 1.22.0
    where : array_like of bool, optional
        Elements to include in the product. See `~numpy.ufunc.reduce`
        for details.
        .. versionadded:: 1.22.0
    Returns
    -----
    nanprod : ndarray
        A new array holding the result is returned unless `out` is
        specified, in which case it is returned.
    See Also
    -----
    numpy.prod : Product across array propagating NaNs.
    isnan : Show which elements are NaN.
    Examples
    -----
    >>> np.nanprod(1)
    1
    >>> np.nanprod([1])
    1
    >>> np.nanprod([1, np.nan])
    1.0
    >>> a = np.array([[1, 2], [3, np.nan]])

a
724: (4)                 Numbers (NaNs) as one. The cumulative product does not change when NaNs
are

```

```

725: (4) encountered and leading NaNs are replaced by ones.
726: (4) Ones are returned for slices that are all-NaN or empty.
727: (4) .. versionadded:: 1.12.0
728: (4) Parameters
729: (4) -----
730: (4) a : array_like
731: (8) Input array.
732: (4) axis : int, optional
733: (8) Axis along which the cumulative product is computed. By default
734: (8) the input is flattened.
735: (4) dtype : dtype, optional
736: (8) Type of the returned array, as well as of the accumulator in which
737: (8) the elements are multiplied. If *dtype* is not specified, it
738: (8) defaults to the dtype of `a`, unless `a` has an integer dtype with
739: (8) a precision less than that of the default platform integer. In
740: (8) that case, the default platform integer is used instead.
741: (4) out : ndarray, optional
742: (8) Alternative output array in which to place the result. It must
743: (8) have the same shape and buffer length as the expected output
744: (8) but the type of the resulting values will be cast if necessary.
745: (4) Returns
746: (4) -----
747: (4) nancumprod : ndarray
748: (8) A new array holding the result is returned unless `out` is
749: (8) specified, in which case it is returned.
750: (4) See Also
751: (4) -----
752: (4) numpy.cumprod : Cumulative product across array propagating NaNs.
753: (4) isnan : Show which elements are NaN.
754: (4) Examples
755: (4) -----
756: (4) >>> np.nancumprod(1)
757: (4) array([1])
758: (4) >>> np.nancumprod([1])
759: (4) array([1])
760: (4) >>> np.nancumprod([1, np.nan])
761: (4) array([1., 1.])
762: (4) >>> a = np.array([[1, 2], [3, np.nan]])
763: (4) >>> np.nancumprod(a)
764: (4) array([1., 2., 6., 6.])
765: (4) >>> np.nancumprod(a, axis=0)
766: (4) array([[1., 2.],
767: (11) [3., 2.]])
768: (4) >>> np.nancumprod(a, axis=1)
769: (4) array([[1., 2.],
770: (11) [3., 3.]])
771: (4) """
772: (4) a, mask = _replace_nan(a, 1)

778: (0) def nanmean(a, axis=None, dtype=None, out=None, keepdims=np._NoValue,
779: (12) *, where=np._NoValue):
780: (4) """
781: (4) Compute the arithmetic mean along the specified axis, ignoring NaNs.
782: (4) Returns the average of the array elements. The average is taken over
783: (4) the flattened array by default, otherwise over the specified axis.
784: (4) `float64` intermediate and return values are used for integer inputs.
785: (4) For all-NaN slices, NaN is returned and a `RuntimeWarning` is raised.
786: (4) .. versionadded:: 1.8.0
787: (4) Parameters
788: (4) -----
789: (4) a : array_like
790: (8) Array containing numbers whose mean is desired. If `a` is not an
791: (8) array, a conversion is attempted.
792: (4) axis : {int, tuple of int, None}, optional
793: (8) Axis or axes along which the means are computed. The default is to

```

```

compute
794: (8)           the mean of the flattened array.
795: (4)           dtype : data-type, optional
796: (8)           Type to use in computing the mean. For integer inputs, the default
797: (8)           is `float64`; for inexact inputs, it is the same as the input
798: (8)           dtype.
799: (4)           out : ndarray, optional
800: (8)           Alternate output array in which to place the result. The default
801: (8)           is ``None``; if provided, it must have the same shape as the
802: (8)           expected output, but the type will be cast if necessary. See
803: (8)           :ref:`ufuncs-output-type` for more details.
804: (4)           keepdims : bool, optional
805: (8)           If this is set to True, the axes which are reduced are left
806: (8)           in the result as dimensions with size one. With this option,
807: (8)           the result will broadcast correctly against the original `a`.
808: (8)           If the value is anything but the default, then
809: (8)           `keepdims` will be passed through to the `mean` or `sum` methods
810: (8)           of sub-classes of `ndarray`. If the sub-classes methods
811: (8)           does not implement `keepdims` any exceptions will be raised.
812: (4)           where : array_like of bool, optional
813: (8)           Elements to include in the mean. See `~numpy.ufunc.reduce` for
details.
814: (8)           .. versionadded:: 1.22.0
815: (4)           Returns
816: (4)           -----
817: (4)           m : ndarray, see dtype parameter above
818: (8)           If `out=None`, returns a new array containing the mean values,
819: (8)           otherwise a reference to the output array is returned. Nan is
820: (8)           returned for slices that contain only NaNs.
821: (4)           See Also
822: (4)           -----
823: (4)           average : Weighted average
824: (4)           mean : Arithmetic mean taken while not ignoring NaNs
825: (4)           var, nanvar
826: (4)           Notes
827: (4)           -----
828: (4)           The arithmetic mean is the sum of the non-NaN elements along the axis
829: (4)           divided by the number of non-NaN elements.
830: (4)           Note that for floating-point input, the mean is computed using the same
831: (4)           precision the input has. Depending on the input data, this can cause
832: (4)           the results to be inaccurate, especially for `float32`. Specifying a
833: (4)           higher-precision accumulator using the `dtype` keyword can alleviate
834: (4)           this issue.
835: (4)           Examples
836: (4)           -----
837: (4)           >>> a = np.array([[1, np.nan], [3, 4]])
838: (4)           >>> np.nanmean(a)
839: (4)           2.6666666666666665
840: (4)           >>> np.nanmean(a, axis=0)
841: (4)           array([2., 4.])
842: (4)           >>> np.nanmean(a, axis=1)
843: (4)           array([1., 3.5]) # may vary
844: (4)           """

```

928: (4)          out : ndarray, optional
929: (8)            Alternative output array in which to place the result. It must
930: (8)            have the same shape and buffer length as the expected output,
931: (8)            but the type (of the output) will be cast if necessary.
932: (4)          overwrite_input : bool, optional
933: (7)            If True, then allow use of memory of input array `a` for
934: (7)            calculations. The input array will be modified by the call to
935: (7)            `median`. This will save memory when you do not need to preserve
936: (7)            the contents of the input array. Treat the input as undefined,
937: (7)            but it will probably be fully or partially sorted. Default is
938: (7)            False. If `overwrite_input` is ``True`` and `a` is not already an
939: (7)            `ndarray`, an error will be raised.
940: (4)          keepdims : bool, optional
941: (8)            If this is set to True, the axes which are reduced are left
942: (8)            in the result as dimensions with size one. With this option,
943: (8)            the result will broadcast correctly against the original `a`.
944: (8)            If this is anything but the default value it will be passed
945: (8)            through (in the special case of an empty array) to the
946: (8)            `mean` function of the underlying array. If the array is
947: (8)            a sub-class and `mean` does not have the kwarg `keepdims` this
948: (8)            will raise a RuntimeError.
949: (4)          Returns
950: (4)          -----
951: (4)          median : ndarray
952: (8)            A new array holding the result. If the input contains integers
953: (8)            or floats smaller than ``float64``, then the output data-type is
954: (8)            ``np.float64``. Otherwise, the data-type of the output is the
955: (8)            same as that of the input. If `out` is specified, that array is
956: (8)            returned instead.
957: (4)          See Also
958: (4)          -----
959: (4)          mean, median, percentile
960: (4)          Notes
961: (4)          -----
962: (4)            Given a vector ``V`` of length ``N``, the median of ``V`` is the
963: (4)            middle value of a sorted copy of ``V``, ``V_sorted`` - i.e.,
964: (4)            ``V_sorted[(N-1)/2]``, when ``N`` is odd and the average of the two
965: (4)            middle values of ``V_sorted`` when ``N`` is even.
966: (4)          Examples
967: (4)          -----
968: (4)          >>> a = np.array([[10.0, 7, 4], [3, 2, 1]])
969: (4)          >>> a[0, 1] = np.nan
970: (4)          >>> a
971: (4)          array([[10., nan,  4.],
972: (11)             [ 3.,  2.,  1.]])

1013: (4)            Compute the qth percentile of the data along the specified axis,
1014: (4)            while ignoring nan values.
1015: (4)            Returns the qth percentile(s) of the array elements.
1016: (4)            .. versionadded:: 1.9.0
1017: (4)            Parameters
1018: (4)            -----
1019: (4)            a : array_like
1020: (8)            Input array or object that can be converted to an array, containing
1021: (8)            nan values to be ignored.
1022: (4)            q : array_like of float
1023: (8)            Percentile or sequence of percentiles to compute, which must be
1024: (8)            between 0 and 100 inclusive.
1025: (4)            axis : {int, tuple of int, None}, optional
1026: (8)            Axis or axes along which the percentiles are computed. The default
1027: (8)            is to compute the percentile(s) along a flattened version of the
1028: (8)            array.
1029: (4)            out : ndarray, optional
1030: (8)            Alternative output array in which to place the result. It must have
1031: (8)            the same shape and buffer length as the expected output, but the
1032: (8)            type (of the output) will be cast if necessary.
1033: (4)            overwrite_input : bool, optional
1034: (8)            If True, then allow the input array `a` to be modified by
1035: (8)            intermediate calculations, to save memory. In this case, the
1036: (8)            contents of the input `a` after this function completes is
1037: (8)            undefined.
1038: (4)            method : str, optional
1039: (8)            This parameter specifies the method to use for estimating the
1040: (8)            percentile. There are many different methods, some unique to NumPy.
1041: (8)            See the notes for explanation. The options sorted by their R type
1042: (8)            as summarized in the H&F paper [1]_ are:
1043: (8)            1. 'inverted_cdf'
1044: (8)            2. 'averaged_inverted_cdf'
1045: (8)            3. 'closest_observation'
1046: (8)            4. 'interpolated_inverted_cdf'
1047: (8)            5. 'hazen'
1048: (8)            6. 'weibull'
1049: (8)            7. 'linear' (default)
1050: (8)            8. 'median_unbiased'
1051: (8)            9. 'normal_unbiased'
1052: (8)            The first three methods are discontinuous. NumPy further defines the
1053: (8)            following discontinuous variations of the default 'linear' (7.)
option:
1054: (8)            * 'lower'
1055: (8)            * 'higher',
1056: (8)            * 'midpoint'
1057: (8)            * 'nearest'
1058: (8)            .. versionchanged:: 1.22.0
1059: (12)            This argument was previously called "interpolation" and only
1060: (12)            offered the "linear" default and last four options.
1061: (4)            keepdims : bool, optional
1062: (8)            If this is set to True, the axes which are reduced are left in
1063: (8)            the result as dimensions with size one. With this option, the
1064: (8)            result will broadcast correctly against the original array `a`.

```

```

1065: (8)             If this is anything but the default value it will be passed
1066: (8)             through (in the special case of an empty array) to the
1067: (8)             `mean` function of the underlying array. If the array is
1068: (8)             a sub-class and `mean` does not have the kwarg `keepdims` this
1069: (8)             will raise a RuntimeError.
1070: (4)             interpolation : str, optional
1071: (8)                 Deprecated name for the method keyword argument.
1072: (8)                 .. deprecated:: 1.22.0
1073: (4)             Returns
1074: (4)
1075: (4)             percentile : scalar or ndarray
1076: (8)                 If `q` is a single percentile and `axis=None`, then the result
1077: (8)                 is a scalar. If multiple percentiles are given, first axis of
1078: (8)                 the result corresponds to the percentiles. The other axes are
1079: (8)                 the axes that remain after the reduction of `a`. If the input
1080: (8)                 contains integers or floats smaller than ``float64``, the output
1081: (8)                 data-type is ``float64``. Otherwise, the output data-type is the
1082: (8)                 same as that of the input. If `out` is specified, that array is
1083: (8)                 returned instead.
1084: (4)             See Also
1085: (4)
1086: (4)             nanmean

1179: (8)                 quantile. There are many different methods, some unique to NumPy.
1180: (8)                 See the notes for explanation. The options sorted by their R type
1181: (8)                 as summarized in the H&F paper [1]_ are:
1182: (8)                 1. 'inverted_cdf'
1183: (8)                 2. 'averaged_inverted_cdf'
1184: (8)                 3. 'closest_observation'
1185: (8)                 4. 'interpolated_inverted_cdf'
1186: (8)                 5. 'hazen'
1187: (8)                 6. 'weibull'
1188: (8)                 7. 'linear' (default)
1189: (8)                 8. 'median_unbiased'
1190: (8)                 9. 'normal_unbiased'
1191: (8)                 The first three methods are discontinuous. NumPy further defines the
1192: (8)                 following discontinuous variations of the default 'linear' (7.)
option:
1193: (8)                 * 'lower'
1194: (8)                 * 'higher',
1195: (8)                 * 'midpoint'
1196: (8)                 * 'nearest'
1197: (8)                 .. versionchanged:: 1.22.0
1198: (12)                   This argument was previously called "interpolation" and only
1199: (12)                   offered the "linear" default and last four options.
1200: (4)             keepdims : bool, optional

```

```

1201: (8)           If this is set to True, the axes which are reduced are left in
1202: (8)           the result as dimensions with size one. With this option, the
1203: (8)           result will broadcast correctly against the original array `a`.
1204: (8)           If this is anything but the default value it will be passed
1205: (8)           through (in the special case of an empty array) to the
1206: (8)           `mean` function of the underlying array. If the array is
1207: (8)           a sub-class and `mean` does not have the kwarg `keepdims` this
1208: (8)           will raise a RuntimeError.
1209: (4)           interpolation : str, optional
1210: (8)               Deprecated name for the method keyword argument.
1211: (8)               .. deprecated:: 1.22.0
1212: (4)           Returns
1213: (4)           -----
1214: (4)           quantile : scalar or ndarray
1215: (8)               If `q` is a single probability and `axis=None`, then the result
1216: (8)               is a scalar. If multiple probability levels are given, first axis of
1217: (8)               the result corresponds to the quantiles. The other axes are
1218: (8)               the axes that remain after the reduction of `a`. If the input
1219: (8)               contains integers or floats smaller than ``float64``, the output
1220: (8)               data-type is ``float64``. Otherwise, the output data-type is the
1221: (8)               same as that of the input. If `out` is specified, that array is
1222: (8)               returned instead.
1223: (4)           See Also
1224: (4)           -----
1225: (4)           quantile
1226: (4)           nanmean, nanmedian
1227: (4)           nanmedian : equivalent to ``nanquantile(..., 0.5)``
1228: (4)           nanpercentile : same as nanquantile, but with q in the range [0, 100].

```

1338: (4)          Parameters
1339: (4)
1340: (4)
1341: (8)          a : array_like
1342: (8)          Array containing numbers whose variance is desired. If `a` is not an
1343: (4)          array, a conversion is attempted.
1344: (8)          axis : {int, tuple of int, None}, optional
1345: (8)          Axis or axes along which the variance is computed. The default is to
compute
1346: (4)          the variance of the flattened array.
1347: (8)          dtype : data-type, optional
1348: (8)          Type to use in computing the variance. For arrays of integer type
1349: (8)          the default is `float64`; for arrays of float types it is the same as
the array type.
1350: (4)          out : ndarray, optional
1351: (8)          Alternate output array in which to place the result. It must have
1352: (8)          the same shape as the expected output, but the type is cast if
necessary.
1353: (8)
1354: (4)          ddof : int, optional
1355: (8)          "Delta Degrees of Freedom": the divisor used in the calculation is
1356: (8)          ``N - ddof``, where ``N`` represents the number of non-NaN
1357: (8)          elements. By default `ddof` is zero.
1358: (4)          keepdims : bool, optional
1359: (8)          If this is set to True, the axes which are reduced are left
1360: (8)          in the result as dimensions with size one. With this option,
1361: (8)          the result will broadcast correctly against the original `a`.
1362: (4)          where : array_like of bool, optional
1363: (8)          Elements to include in the variance. See `~numpy.ufunc.reduce` for
1364: (8)          details.
1365: (8)          .. versionadded:: 1.22.0
1366: (4)          Returns
1367: (4)
1368: (4)          variance : ndarray, see dtype parameter above
1369: (8)          If `out` is None, return a new array containing the variance,
1370: (8)          otherwise return a reference to the output array. If ddof is >= the
1371: (8)          number of non-NaN elements in a slice or the slice contains only
1372: (8)          NaNs, then the result for that slice is NaN.
1373: (4)          See Also
1374: (4)
1375: (4)          std : Standard deviation
1376: (4)          mean : Average
1377: (4)          var : Variance while not ignoring NaNs
1378: (4)          nanstd, nanmean
1379: (4)          :ref:`ufuncs-output-type`
1380: (4)          Notes
1381: (4)
1382: (4)          The variance is the average of the squared deviations from the mean,
1383: (4)          i.e., ``var = mean(abs(x - x.mean())**2)``.
1384: (4)          The mean is normally calculated as ``x.sum() / N``, where ``N = len(x)``.
1385: (4)          If, however, `ddof` is specified, the divisor ``N - ddof`` is used
1386: (4)          instead. In standard statistical practice, ``ddof=1`` provides an
1387: (4)          unbiased estimator of the variance of a hypothetical infinite
1388: (4)          population. ``ddof=0`` provides a maximum likelihood estimate of the
1389: (4)          variance for normally distributed variables.
1390: (4)          Note that for complex numbers, the absolute value is taken before
1391: (4)          squaring, so that the result is always real and nonnegative.
1392: (4)          For floating-point input, the variance is computed using the same
1393: (4)          precision the input has. Depending on the input data, this can cause
1394: (4)          the results to be inaccurate, especially for `float32` (see example
1395: (4)          below). Specifying a higher-accuracy accumulator using the ``dtype``
1396: (4)          keyword can alleviate this issue.
1397: (4)          For this function to work on sub-classes of ndarray, they must define
1398: (4)          `sum` with the kwarg `keepdims`
1399: (4)          Examples
1400: (4)
1401: (4)          >>> a = np.array([[1, np.nan], [3, 4]])
1402: (4)          >>> np.nanvar(a)
1403: (4)          1.5555555555555554
1404: (4)          >>> np.nanvar(a, axis=0)
1405: (4)          array([1.,  0.])

```

    """
    Compute the standard deviation along the specified axis, while
    ignoring NaNs.
    Returns the standard deviation, a measure of the spread of a
    distribution, of the non-NaN array elements. The standard deviation is
    computed for the flattened array by default, otherwise over the
    specified axis.
    For all-NaN slices or slices with zero degrees of freedom, NaN is
    returned and a `RuntimeWarning` is raised.
    .. versionadded:: 1.8.0
    Parameters
    -----
    a : array_like
        Calculate the standard deviation of the non-NaN values.
    axis : {int, tuple of int, None}, optional
        Axis or axes along which the standard deviation is computed. The
        to compute the standard deviation of the flattened array.
    dtype : dtype, optional
        Type to use in computing the standard deviation. For arrays of
    """

```

```

1474: (8)             integer type the default is float64, for arrays of float types it
1475: (8)             is the same as the array type.
1476: (4)             out : ndarray, optional
1477: (8)                 Alternative output array in which to place the result. It must have
1478: (8)                 the same shape as the expected output but the type (of the
1479: (8)                 calculated values) will be cast if necessary.
1480: (4)             ddof : int, optional
1481: (8)                 Means Delta Degrees of Freedom. The divisor used in calculations
1482: (8)                 is ``N - ddof``, where ``N`` represents the number of non-NaN
1483: (8)                 elements. By default `ddof` is zero.
1484: (4)             keepdims : bool, optional
1485: (8)                 If this is set to True, the axes which are reduced are left
1486: (8)                 in the result as dimensions with size one. With this option,
1487: (8)                 the result will broadcast correctly against the original `a`.
1488: (8)                 If this value is anything but the default it is passed through
1489: (8)                 as-is to the relevant functions of the sub-classes. If these
1490: (8)                 functions do not have a `keepdims` kwarg, a RuntimeError will
1491: (8)                 be raised.
1492: (4)             where : array_like of bool, optional
1493: (8)                 Elements to include in the standard deviation.
1494: (8)                 See `~numpy.ufunc.reduce` for details.
1495: (8)             .. versionadded:: 1.22.0
1496: (4)             Returns
1497: (4)             -----
1498: (4)             standard_deviation : ndarray, see dtype parameter above.
1499: (8)                 If `out` is None, return a new array containing the standard
1500: (8)                 deviation, otherwise return a reference to the output array. If
1501: (8)                 ddof is >= the number of non-NaN elements in a slice or the slice
1502: (8)                 contains only NaNs, then the result for that slice is NaN.
1503: (4)             See Also
1504: (4)             -----
1505: (4)             var, mean, std
1506: (4)             nanvar, nanmean
1507: (4)             :ref:`ufuncs-output-type`
1508: (4)             Notes
1509: (4)             -----
1510: (4)             The standard deviation is the square root of the average of the squared
1511: (4)             deviations from the mean: ``std = sqrt(mean(abs(x - x.mean())**2))``.
1512: (4)             The average squared deviation is normally calculated as
1513: (4)             ``x.sum() / N``, where ``N = len(x)``. If, however, `ddof` is
1514: (4)             specified, the divisor ``N - ddof`` is used instead. In standard
1515: (4)             statistical practice, ``ddof=1`` provides an unbiased estimator of the
1516: (4)             variance of the infinite population. ``ddof=0`` provides a maximum
1517: (4)             likelihood estimate of the variance for normally distributed variables.
1518: (4)             The standard deviation computed in this function is the square root of
1519: (4)             the estimated variance, so even with ``ddof=1``, it will not be an
1520: (4)             unbiased estimate of the standard deviation per se.
1521: (4)             Note that, for complex numbers, `std` takes the absolute value before
1522: (4)             squaring, so that the result is always real and nonnegative.
1523: (4)             For floating-point input, the *std* is computed using the same
1524: (4)             precision the input has. Depending on the input data, this can cause
1525: (4)             the results to be inaccurate, especially for float32 (see example
1526: (4)             below). Specifying a higher-accuracy accumulator using the `dtype`
1527: (4)             keyword can alleviate this issue.
1528: (4)             Examples
1529: (4)             -----
1530: (4)             >>> a = np.array([[1, np.nan], [3, 4]])
1531: (4)             >>> np.nanstd(a)
1532: (4)             1.247219128924647
1533: (4)             >>> np.nanstd(a, axis=0)
1534: (4)             array([1., 0.])
1535: (4)             >>> np.nanstd(a, axis=1)
1536: (4)             array([0.,  0.5]) # may vary
1537: (4)             """
1538: (4)             var = nanvar(a, axis=axis, dtype=dtype, out=out, ddof=ddof,
1539: (17)                         keepdims=keepdims, where=where)
1540: (4)             if isinstance(var, np.ndarray):
1541: (8)                 std = np.sqrt(var, out=var)

84: (0) class NpzFile(Mapping):
85: (4)     """
86: (4)         NpzFile(fid)
87: (4)         A dictionary-like object with lazy-loading of files in the zipped
88: (4)         archive provided on construction.
89: (4)         `NpzFile` is used to load files in the NumPy ``.npz`` data archive
90: (4)         format. It assumes that files in the archive have a ``.npy`` extension,
91: (4)         other files are ignored.
92: (4)         The arrays and file strings are lazily loaded on either
93: (4)         getitem access using ``obj['key']`` or attribute lookup using
94: (4)         ``obj.f.key``. A list of all files (without ``.npy`` extensions) can
95: (4)         be obtained with ``obj.files`` and the ZipFile object itself using
96: (4)         ``obj.zip``.
97: (4)         Attributes
98: (4)         -----
99: (4)         files : list of str
100: (8)             List of all files in the archive with a ``.npy`` extension.
101: (4)         zip : ZipFile instance
102: (8)             The ZipFile object initialized with the zipped archive.
103: (4)         f : BagObj instance
104: (8)             An object on which attribute can be performed as an alternative
105: (8)             to getitem access on the `NpzFile` instance itself.
106: (4)         allow_pickle : bool, optional
107: (8)             Allow loading pickled data. Default: False
108: (8)             .. versionchanged:: 1.16.3
109: (12)                 Made default False in response to CVE-2019-6446.
110: (4)         pickle_kwds : dict, optional
111: (8)             Additional keyword arguments to pass on to pickle.load.
112: (8)             These are only useful when loading object arrays saved on
113: (8)             Python 2 when using Python 3.
114: (4)         max_header_size : int, optional
115: (8)             Maximum allowed size of the header. Large headers may not be safe
116: (8)             to load securely and thus require explicitly passing a larger value.
117: (8)             See :py:func:`ast.literal_eval()` for details.
118: (8)             This option is ignored when `allow_pickle` is passed. In that case
119: (8)             the file is by definition trusted and the limit is unnecessary.
120: (4)         Parameters
121: (4)         -----
122: (4)         fid : file or str
123: (8)             The zipped archive to open. This is either a file-like object
124: (8)             or a string containing the path to the archive.
125: (4)         own_fid : bool, optional
126: (8)             Whether NpzFile should close the file handle.
127: (8)             Requires that `fid` is a file-like object.
128: (4)         Examples

```

```

129: (4)          -----
130: (4)          >>> from tempfile import TemporaryFile
131: (4)          >>> outfile = TemporaryFile()
132: (4)          >>> x = np.arange(10)
133: (4)          >>> y = np.sin(x)
134: (4)          >>> np.savez(outfile, x=x, y=y)
135: (4)          >>> _ = outfile.seek(0)
136: (4)          >>> npz = np.load(outfile)
137: (4)          >>> isinstance(npz, np.lib.npyio.NpzFile)

225: (4)             """
226: (4)                 Load arrays or pickled objects from ``.npy``, ``.npz`` or pickled files.
227: (4)                 .. warning:: Loading files that contain object arrays uses the ``pickle``
228: (17)                     module, which is not secure against erroneous or maliciously
229: (17)                     constructed data. Consider passing ``allow_pickle=False`` to
230: (17)                     load data that is known not to contain object arrays for the
231: (17)                     safer handling of untrusted sources.
232: (4)             Parameters
233: (4)             -----
234: (4)             file : file-like object, string, or pathlib.Path
235: (8)                 The file to read. File-like objects must support the
236: (8)                 ``seek()`` and ``read()`` methods and must always
237: (8)                 be opened in binary mode. Pickled files require that the
238: (8)                 file-like object support the ``readline()`` method as well.
239: (4)             mmap_mode : {None, 'r+', 'r', 'w+', 'c'}, optional
240: (8)                 If not None, then memory-map the file, using the given mode (see
241: (8)                   `numpy.memmap` for a detailed description of the modes). A
242: (8)                   memory-mapped array is kept on disk. However, it can be accessed
243: (8)                   and sliced like any ndarray. Memory mapping is especially useful
244: (8)                   for accessing small fragments of large files without reading the
245: (8)                   entire file into memory.
246: (4)             allow_pickle : bool, optional
247: (8)                 Allow loading pickled object arrays stored in npy files. Reasons for
248: (8)                 disallowing pickles include security, as loading pickled data can
249: (8)                 execute arbitrary code. If pickles are disallowed, loading object
250: (8)                 arrays will fail. Default: False
251: (8)                 .. versionchanged:: 1.16.3
252: (12)                     Made default False in response to CVE-2019-6446.
253: (4)             fix_imports : bool, optional
254: (8)                 Only useful when loading Python 2 generated pickled files on Python 3,
255: (8)                 which includes npy/npz files containing object arrays. If
`fix_imports`:
256: (8)                 is True, pickle will try to map the old Python 2 names to the new
names
257: (8)                 used in Python 3.
258: (4)             encoding : str, optional
259: (8)                 What encoding to use when reading Python 2 strings. Only useful when
260: (8)                 loading Python 2 generated pickled files in Python 3, which includes
261: (8)                 npy/npz files containing object arrays. Values other than 'latin1',
262: (8)                 'ASCII', and 'bytes' are not allowed, as they can corrupt numerical
263: (8)                 data. Default: 'ASCII'
264: (4)             max_header_size : int, optional

```

```

265: (8)                         Maximum allowed size of the header. Large headers may not be safe
266: (8)                         to load securely and thus require explicitly passing a larger value.
267: (8)                         See :py:func:`ast.literal_eval()` for details.
268: (8)                         This option is ignored when `allow_pickle` is passed. In that case
269: (8)                         the file is by definition trusted and the limit is unnecessary.
270: (4)                         Returns
271: (4)                         -----
272: (4)                         result : array, tuple, dict, etc.
273: (8)                         Data stored in the file. For ``.npz`` files, the returned instance
274: (8)                         of NpzFile class must be closed to avoid leaking file descriptors.
275: (4)                         Raises
276: (4)                         -----

```

466: (4)          savez_compressed : Save several arrays into a compressed ``.npz`` archive
467: (4)          Notes
468: (4)
469: (4)          -----
470: (4)          The ``.npz`` file format is a zipped archive of files named after the
471: (4)          variables they contain. The archive is not compressed and each file
472: (4)          in the archive contains one variable in ``.npy`` format. For a
473: (4)          description of the ``.npy`` format, see :py:mod:`numpy.lib.format`.
474: (4)          When opening the saved ``.npz`` file with `load` a `NpzFile` object is
475: (4)          returned. This is a dictionary-like object which can be queried for
476: (4)          its list of arrays (with the ``.files`` attribute), and for the arrays
477: (4)          themselves.
478: (4)          Keys passed in `kwds` are used as filenames inside the ZIP archive.
479: (4)          Therefore, keys should be valid filenames; e.g., avoid keys that begin
480: (4)          with
481: (4)          ``/`` or contain ``...``.
482: (4)          When naming variables with keyword arguments, it is not possible to name a
483: (4)          variable ``file``, as this would cause the ``file`` argument to be defined
484: (4)          twice in the call to ``savez``.
485: (4)          Examples
486: (4)          -----
487: (4)          >>> from tempfile import TemporaryFile
488: (4)          >>> outfile = TemporaryFile()
489: (4)          >>> x = np.arange(10)
490: (4)          >>> y = np.sin(x)
491: (4)          Using `savez` with ``*args, the arrays are saved with default names.
492: (4)          >>> np.savez(outfile, x, y)
493: (4)          >>> _ = outfile.seek(0) # Only needed here to simulate closing & reopening
494: (4)          file
495: (4)          >>> npzfile = np.load(outfile)
496: (4)          >>> npzfile.files
497: (4)          ['arr_0', 'arr_1']
498: (4)          >>> npzfile['arr_0']
499: (4)          array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
500: (4)          Using `savez` with ``**kwds, the arrays are saved with the keyword names.
501: (4)          >>> outfile = TemporaryFile()
502: (4)          >>> np.savez(outfile, x=x, y=y)
503: (4)          >>> _ = outfile.seek(0)
504: (4)          >>> npzfile = np.load(outfile)
505: (4)          >>> sorted(npzfile.files)
506: (4)          ['x', 'y']
507: (4)          >>> npzfile['x']

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

876: (8)           the data-type.
877: (4)           comments : str or sequence of str or None, optional
878: (8)           The characters or list of characters used to indicate the start of a
879: (8)           comment. None implies no comments. For backwards compatibility, byte
880: (8)           strings will be decoded as 'latin1'. The default is '#'.
881: (4)           delimiter : str, optional
882: (8)           The character used to separate the values. For backwards
compatibility,
883: (8)           byte strings will be decoded as 'latin1'. The default is whitespace.
884: (8)           .. versionchanged:: 1.23.0
885: (11)          Only single character delimiters are supported. Newline characters
886: (11)          cannot be used as the delimiter.
887: (4)           converters : dict or callable, optional
888: (8)           Converter functions to customize value parsing. If `converters` is
889: (8)           callable, the function is applied to all columns, else it must be a
890: (8)           dict that maps column number to a parser function.
891: (8)           See examples for further details.
892: (8)           Default: None.
893: (8)           .. versionchanged:: 1.23.0
894: (11)          The ability to pass a single callable to be applied to all columns
895: (11)          was added.
896: (4)           skiprows : int, optional
897: (8)           Skip the first `skiprows` lines, including comments; default: 0.
898: (4)           usecols : int or sequence, optional
899: (8)           Which columns to read, with 0 being the first. For example,
900: (8)           ``usecols = (1,4,5)`` will extract the 2nd, 5th and 6th columns.
901: (8)           The default, None, results in all columns being read.
902: (8)           .. versionchanged:: 1.11.0
903: (12)          When a single column has to be read it is possible to use
904: (12)          an integer instead of a tuple. E.g ``usecols = 3`` reads the
905: (12)          fourth column the same way as ``usecols = (3,)`` would.
906: (4)           unpack : bool, optional
907: (8)           If True, the returned array is transposed, so that arguments may be
908: (8)           unpacked using ``x, y, z = loadtxt(...)``. When used with a
909: (8)           structured data-type, arrays are returned for each field.
910: (8)           Default is False.
911: (4)           ndmin : int, optional
912: (8)           The returned array will have at least `ndmin` dimensions.
913: (8)           Otherwise mono-dimensional axes will be squeezed.
914: (8)           Legal values: 0 (default), 1 or 2.
915: (8)           .. versionadded:: 1.6.0
916: (4)           encoding : str, optional
917: (8)           Encoding used to decode the inputfile. Does not apply to input
streams.
918: (8)           The special value 'bytes' enables backward compatibility workarounds
919: (8)           that ensures you receive byte arrays as results if possible and passes
920: (8)           'latin1' encoded strings to converters. Override this value to receive
921: (8)           unicode arrays and pass strings as input to converters. If set to
None
922: (8)           the system default is used. The default value is 'bytes'.
923: (8)           .. versionadded:: 1.14.0
924: (4)           max_rows : int, optional
925: (8)           Read `max_rows` rows of content after `skiprows` lines. The default is
926: (8)           to read all the rows. Note that empty rows containing no data such as
927: (8)           empty lines and comment lines are not counted towards `max_rows`,
928: (8)           while such lines are counted in `skiprows`.
929: (8)           .. versionadded:: 1.16.0
930: (8)           .. versionchanged:: 1.23.0
931: (12)          Lines containing no data, including comment lines (e.g., lines
932: (12)          starting with '#' or as specified via `comments`) are not counted
933: (12)          towards `max_rows`.
934: (4)           quotechar : unicode character or None, optional
935: (8)           The character used to denote the start and end of a quoted item.
936: (8)           Occurrences of the delimiter or comment characters are ignored within
937: (8)           a quoted item. The default value is ``quotechar=None``, which means
938: (8)           quoting support is disabled.
939: (8)           If two consecutive instances of `quotechar` are found within a quoted
940: (8)           field, the first is treated as an escape character. See examples.
941: (8)           .. versionadded:: 1.23.0

```

```

942: (4) ${ARRAY_FUNCTION_LIKE}
943: (8)     .. versionadded:: 1.20.0
944: (4) Returns
945: (4)
946: (4) out : ndarray
947: (8)     Data read from the text file.
948: (4) See Also
949: (4)
950: (4) -----
951: (4) load, fromstring, fromregex
952: (4) genfromtxt : Load data with missing values handled as specified.
953: (4) scipy.io.loadmat : reads MATLAB data files
954: (4) Notes
955: (4) -----
956: (4) This function aims to be a fast reader for simply formatted files. The
957: (4) `genfromtxt` function provides more sophisticated handling of, e.g.,
958: (4) lines with missing values.
959: (4) Each row in the input text file must have the same number of values to be
960: (4) able to read all values. If all rows do not have same number of values, a
961: (4) subset of up to n columns (where n is the least number of values present
962: (4) in all rows) can be read by specifying the columns via `usecols`.
963: (4) .. versionadded:: 1.10.0
964: (4) The strings produced by the Python float.hex method can be used as
965: (4) input for floats.
966: (4) Examples
967: (4) -----
968: (4) >>> from io import StringIO # StringIO behaves like a file object
969: (4) >>> c = StringIO("0 1\n2 3")
970: (4) >>> np.loadtxt(c)
971: (11) array([[0., 1.],
972: (4)           [2., 3.]])
973: (4) >>> d = StringIO("M 21 72\nF 35 58")
974: (4) >>> np.loadtxt(d, dtype={'names': ('gender', 'age', 'weight'),
975: (4)                           ...                               'formats': ('S1', 'i4', 'f4')})
976: (10) array([(b'M', 21, 72.), (b'F', 35, 58.)],
977: (4)         dtype=[('gender', 'S1'), ('age', '<i4'), ('weight', '<f4')])
978: (4) >>> c = StringIO("1,0,2\n3,0,4")
979: (4) >>> x, y = np.loadtxt(c, delimiter=',', usecols=(0, 2), unpack=True)
980: (4) >>> x
981: (4) array([1., 3.])
982: (4) >>> y
983: (4) array([2., 4.])
984: (4) The `converters` argument is used to specify functions to preprocess the
985: (4) text prior to parsing. `converters` can be a dictionary that maps
986: (4) preprocessing functions to each column:
987: (4) >>> s = StringIO("1.618, 2.296\n3.141, 4.669\n")
988: (4) >>> conv = {
989: (4)   ...     0: lambda x: np.floor(float(x)), # conversion fn for column 0
990: (4)   ...     1: lambda x: np.ceil(float(x)), # conversion fn for column 1
991: (4)   ...
992: (4) >>> np.loadtxt(s, delimiter=",", converters=conv)
993: (11) array([[1., 3.],
994: (4)           [3., 5.]])
995: (4) `converters` can be a callable instead of a dictionary, in which case it
996: (4) is applied to all columns:
997: (4) >>> s = StringIO("0xDE 0xAD\n0xC0 0xDE")
998: (4) >>> import functools
999: (4) >>> conv = functools.partial(int, base=16)
1000: (4) >>> np.loadtxt(s, converters=conv)
1001: (11) array([[222., 173.],
1002: (4)           [192., 222.]])
1003: (4) This example shows how `converters` can be used to convert a field
1004: (4) with a trailing minus sign into a negative number.
1005: (4) >>> s = StringIO('10.01 31.25-\n19.22 64.31\n17.57- 63.94')
1006: (4) >>> def conv(fld):
1007: (4)   ...     return -float(fld[:-1]) if fld.endswith(b'-') else float(fld)
1008: (4)   ...
1009: (4) >>> np.loadtxt(s, converters=conv)
1010: (11) array([[ 10.01, -31.25],
1011: (4)           [ 19.22,  64.31],
```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1011: (11) [-17.57, 63.94]])
1012: (4) Using a callable as the converter can be particularly useful for handling
1013: (4) values with different formatting, e.g. floats with underscores:
1014: (4) >>> s = StringIO("1 2.7 100_000")
1015: (4) >>> np.loadtxt(s, converters=float)
1016: (4) array([1.e+00, 2.7e+00, 1.e+05])
1017: (4) This idea can be extended to automatically handle values specified in
1018: (4) many different formats:
1019: (4) >>> def conv(val):
1020: (4) ...     try:
1021: (4) ...         return float(val)
1022: (4) ...     except ValueError:
1023: (4) ...         return float.fromhex(val)
1024: (4) >>> s = StringIO("1, 2.5, 3_000, 0b4, 0x1.4000000000000p+2")
1025: (4) >>> np.loadtxt(s, delimiter=",", converters=conv, encoding=None)
1026: (4) array([1.0e+00, 2.5e+00, 3.0e+03, 1.8e+02, 5.0e+00])
1027: (4) Note that with the default ``encoding="bytes```, the inputs to the
1028: (4) converter function are latin-1 encoded byte strings. To deactivate the
1029: (4) implicit encoding prior to conversion, use ``encoding=None``
1030: (4) >>> s = StringIO('10.01 31.25-\n19.22 64.31\n17.57- 63.94')
1031: (4) >>> conv = lambda x: -float(x[:-1]) if x.endswith('-') else float(x)
1032: (4) >>> np.loadtxt(s, converters=conv, encoding=None)
1033: (4) array([[ 10.01, -31.25],
1034: (11) [ 19.22, 64.31],
1035: (11) [-17.57, 63.94]])
1036: (4) Support for quoted fields is enabled with the `quotechar` parameter.
1037: (4) Comment and delimiter characters are ignored when they appear within a
1038: (4) quoted item delineated by `quotechar`:
1039: (4) >>> s = StringIO('"alpha, #42", 10.0\n"beta, #64", 2.0\n')
1040: (4) >>> dtype = np.dtype([('label', 'U12'), ('value', float)])
1041: (4) >>> np.loadtxt(s, dtype=dtype, delimiter=',', quotechar='\'')
1042: (4) array([('alpha, #42', 10.), ('beta, #64', 2.)],
1043: (10) dtype=[('label', '<U12'), ('value', '<f8')])
1044: (4) Quoted fields can be separated by multiple whitespace characters:
1045: (4) >>> s = StringIO('"alpha, #42"      10.0\n"beta, #64" 2.0\n')
1046: (4) >>> dtype = np.dtype([('label', 'U12'), ('value', float)])
1047: (4) >>> np.loadtxt(s, dtype=dtype, delimiter=None, quotechar='\'')
1048: (4) array([('alpha, #42', 10.), ('beta, #64', 2.)],
1049: (10) dtype=[('label', '<U12'), ('value', '<f8')])
1050: (4) Two consecutive quote characters within a quoted field are treated as a
1051: (4) single escaped character:
1052: (4) >>> s = StringIO('Hello, my name is ""Monty""!"')
1053: (4) >>> np.loadtxt(s, dtype="U", delimiter=",", quotechar='\'')
1054: (4) array('Hello, my name is "Monty"!', dtype='<U26')
1055: (4) Read subset of columns when all rows do not contain equal number of
values:
1056: (4) >>> d = StringIO("1 2\n2 4\n3 9 12\n4 16 20")
1057: (4) >>> np.loadtxt(d, usecols=(0, 1))
1058: (4) array([[ 1.,  2.],
1059: (11) [ 2.,  4.],
1060: (11) [ 3.,  9.],
1061: (11) [ 4., 16.]])
1062: (4) """

    """
    Save an array to a text file.

    Parameters
    -----
    fname : filename or file handle
        If the filename ends in ``.gz``, the file is automatically saved in
        compressed gzip format. `loadtxt` understands gzipped files
        transparently.
    X : 1D or 2D array_like
        Data to be saved to a text file.
    fmt : str or sequence of strs, optional
        A single format (%10.5f), a sequence of formats, or a
        multi-format string, e.g. 'Iteration %d -- %10.5f', in which
        case `delimiter` is ignored. For complex `X`, the legal options
        for `fmt` are:
        * a single specifier, `fmt='%.4e'`, resulting in numbers formatted
          like `'( %s+%sj)' % (fmt, fmt)`
        * a full string specifying every real and imaginary part, e.g.
          ``%.4e %+4ej %.4e %+4ej %.4e %+4ej`` for 3 columns
        * a list of specifiers, one per column - in this case, the real
          and imaginary part must have separate specifiers,
          e.g. `'[%.3e + %.3ej', '(%.15e%+.15ej)'` for 2 columns
    delimiter : str, optional
        String or character separating columns.
    newline : str, optional
        String or character separating lines.
        .. versionadded:: 1.5.0
    header : str, optional
        String that will be written at the beginning of the file.
        .. versionadded:: 1.7.0
    footer : str, optional
        String that will be written at the end of the file.
        .. versionadded:: 1.7.0
    comments : str, optional
        String that will be prepended to the ``header`` and ``footer``
        to mark them as comments. Default: '# ', as expected by e.g.
        ``numpy.loadtxt``.
        .. versionadded:: 1.7.0
    encoding : {None, str}, optional
        Encoding used to encode the outputfile. Does not apply to output
        streams. If the encoding is something other than 'bytes' or 'latin1'
        you will not be able to load the file in NumPy versions < 1.14.
        is 'latin1'.
        .. versionadded:: 1.14.0

@set_module('numpy')
def fromregex(file, regexp, dtype, encoding=None):
    """
    Construct an array from a text file, using regular expression parsing.
    The returned array is always a structured array, and is constructed from
    all matches of the regular expression in the file. Groups in the regular
    expression are converted to fields of the structured array.

    Parameters
    -----
    file : path or file
        Filename or file object to read.
        .. versionchanged:: 1.22.0
            Now accepts `os.PathLike` implementations.
    regexp : str or regexp
        Regular expression used to parse the file.
        Groups in the regular expression correspond to fields in the dtype.
    dtype : dtype or list of dtypes
        Dtype for the structured array; must be a structured datatype.
    encoding : str, optional
        Encoding used to decode the inputfile. Does not apply to input
        .. versionadded:: 1.14.0
    Returns
    -----
    output : ndarray
        The output array, containing the part of the content of `file` that
        was matched by `regexp`. `output` is always a structured array.
    Raises
    -----
    TypeError
        When `dtype` is not a valid dtype for a structured array.
    See Also
    -----
    fromstring, loadtxt
    Notes
    -----
    Dtypes for structured arrays can be specified in several forms, but all
    forms specify at least the data type and field name. For details see
    `basics.rec`.
    Examples
    -----
    >>> from io import StringIO
    >>> text = StringIO("1312 foo\n1534 bar\n444 qux")
    >>> regexp = r"(\d+)\s+(...)" # match [digits, whitespace, anything]
    >>> output = np.fromregex(text, regexp,
    ...                         [('num', np.int64), ('key', 'S3')])
    >>> output
    array([(1312, b'foo'), (1534, b'bar'), (444, b'qux')],  

          dtype=[('num', '<i8'), ('key', 'S3')])
    >>> output['num']
    array([1312, 1534, 444])
    """

    """
    Load data from a text file, with missing values handled as specified.
    Each line past the first `skip_header` lines is split at the `delimiter`
    character, and characters following the `comments` character are
    discarded.

    Parameters
    -----
    fname : file, str, pathlib.Path, list of str, generator
        File, filename, list, or generator to read. If the filename
        extension is ``.gz`` or ``.bz2``, the file is first decompressed. Note
        that generators must return bytes or strings. The strings
        in a list or produced by a generator are treated as lines.
    dtype : dtype, optional
        Data type of the resulting array.
        If None, the dtypes will be determined by the contents of each
        column, individually.
    comments : str, optional
        The character used to indicate the start of a comment.
        All the characters occurring on a line after a comment are discarded.
    delimiter : str, int, or sequence, optional
        The string used to separate values. By default, any consecutive
        whitespaces act as delimiter. An integer or sequence of integers
        can also be provided as width(s) of each field.
    skiprows : int, optional
        `skiprows` was removed in numpy 1.10. Please use `skip_header` instead.
    skip_header : int, optional
        The number of lines to skip at the beginning of the file.
    skip_footer : int, optional
        The number of lines to skip at the end of the file.
    converters : variable, optional
        The set of functions that convert the data of a column to a value.
        The converters can also be used to provide a default value
        for missing data: ``converters = {3: lambda s: float(s or 0)}``.
    missing : variable, optional
        `missing` was removed in numpy 1.10. Please use `missing_values` instead.
    missing_values : variable, optional
        The set of strings corresponding to missing data.
    filling_values : variable, optional
        The set of values to be used as default when the data are missing.
    usecols : sequence, optional

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

1416: (8)           Which columns to read, with 0 being the first. For example,
1417: (8)           ``usecols = (1, 4, 5)`` will extract the 2nd, 5th and 6th columns.
1418: (4)           names : {None, True, str, sequence}, optional
1419: (8)           If `names` is True, the field names are read from the first line after
1420: (8)           the first `skip_header` lines. This line can optionally be preceded
1421: (8)           by a comment delimiter. If `names` is a sequence or a single-string of
1422: (8)           comma-separated names, the names will be used to define the field
names
1423: (8)           in a structured dtype. If `names` is None, the names of the dtype
1424: (8)           fields will be used, if any.
1425: (4)           excludelist : sequence, optional
1426: (8)           A list of names to exclude. This list is appended to the default list
1427: (8)           ['return', 'file', 'print']. Excluded names are appended with an
1428: (8)           underscore: for example, `file` would become `file_`.
deletechars : str, optional
1429: (4)           A string combining invalid characters that must be deleted from the
1430: (8)           names.
defaultfmt : str, optional
1431: (8)           A format used to define default field names, such as "f%i" or
"f %02i".
1432: (4)
1433: (8)           A format used to define default field names, such as "f%i" or
"f %02i".
1434: (4)           autostrip : bool, optional
1435: (8)           Whether to automatically strip white spaces from the variables.
1436: (4)           replace_space : char, optional
1437: (8)           Character(s) used in replacement of white spaces in the variable
1438: (8)           names. By default, use a '_'.
case_sensitive : {True, False, 'upper', 'lower'}, optional
1439: (4)           If True, field names are case sensitive.
1440: (8)           If False or 'upper', field names are converted to upper case.
1441: (8)           If 'lower', field names are converted to lower case.
1442: (8)
1443: (4)           unpack : bool, optional
1444: (8)           If True, the returned array is transposed, so that arguments may be
1445: (8)           unpacked using ``x, y, z = genfromtxt(...)``. When used with a
1446: (8)           structured data-type, arrays are returned for each field.
1447: (8)           Default is False.
1448: (4)           usemask : bool, optional
1449: (8)           If True, return a masked array.
1450: (8)           If False, return a regular array.
1451: (4)           loose : bool, optional
1452: (8)           If True, do not raise errors for invalid values.
invalid_raise : bool, optional
1453: (4)           If True, an exception is raised if an inconsistency is detected in the
1454: (8)           number of columns.
1455: (8)           If False, a warning is emitted and the offending lines are skipped.
1456: (8)
1457: (4)           max_rows : int, optional
1458: (8)           The maximum number of rows to read. Must not be used with skip_footer
1459: (8)           at the same time. If given, the value must be at least 1. Default is
1460: (8)           to read the entire file.
1461: (8)           .. versionadded:: 1.10.0
encoding : str, optional
1462: (4)           Encoding used to decode the inputfile. Does not apply when `fname` is
1463: (8)           a file object. The special value 'bytes' enables backward
compatibility
1464: (8)
1465: (8)           workarounds that ensure that you receive byte arrays when possible
1466: (8)           and passes latin1 encoded strings to converters. Override this value
to
1467: (8)           receive unicode arrays and pass strings as input to converters. If
set
1468: (8)           to None the system default is used. The default value is 'bytes'.
1469: (8)           .. versionadded:: 1.14.0
1470: (4)           ndmin : int, optional
1471: (8)           Same parameter as `loadtxt`
1472: (8)           .. versionadded:: 1.23.0
${ARRAY_FUNCTION_LIKE}
1473: (4)
1474: (8)           .. versionadded:: 1.20.0
1475: (4)           Returns
1476: (4)           -----
1477: (4)           out : ndarray
1478: (8)           Data read from the text file. If `usemask` is True, this is a
1479: (8)           masked array.

1481: (4)             -----
1482: (4)             numpy.loadtxt : equivalent function when no data is missing.
1483: (4)             Notes
1484: (4)             -----
1485: (4)             * When spaces are used as delimiters, or when no delimiter has been given
1486: (6)             as input, there should not be any missing data between two fields.
1487: (4)             * When the variables are named (either by a flexible dtype or with
`names`),
1488: (6)             there must not be any header in the file (else a ValueError
1489: (6)             exception is raised).
1490: (4)             * Individual values are not stripped of spaces by default.
1491: (6)             When using a custom converter, make sure the function does remove
spaces.

348: (4)                 :doc:`transition guide p(x) = p[0] * x^{*deg} + \dots + p[deg]`` of degree `deg`
350: (4)                 to points `(x, y)`. Returns a vector of coefficients `p` that minimises
351: (4)                 the squared error in the order `deg`, `deg-1`, ... `0`.
352: (4)                 The `Polynomial.fit <numpy.polynomial.polynomial.Polynomial.fit>` class
353: (4)                 method is recommended for new code as it is more stable numerically. See
354: (4)                 the documentation of the method for more information.
355: (4)             Parameters
356: (4)             -----
357: (4)             x : array_like, shape (M,)
358: (4)                 x-coordinates of the M sample points `` $(x[i], y[i])$ ``.
359: (4)             y : array_like, shape (M,) or (M, K)
360: (4)                 y-coordinates of the sample points. Several data sets of sample
361: (4)                 points sharing the same x-coordinates can be fitted at once by
362: (4)                 passing in a 2D-array that contains one dataset per column.
363: (4)             deg : int

```

```

362: (8) Degree of the fitting polynomial
363: (4) rcond : float, optional
364: (8) Relative condition number of the fit. Singular values smaller than
365: (8) this relative to the largest singular value will be ignored. The
366: (8) default value is len(x)*eps, where eps is the relative precision of
367: (8) the float type, about 2e-16 in most cases.
368: (4) full : bool, optional
369: (8) Switch determining nature of return value. When it is False (the
370: (8) default) just the coefficients are returned, when True diagnostic
371: (8) information from the singular value decomposition is also returned.
372: (4) w : array_like, shape (M,), optional
373: (8) Weights. If not None, the weight ``w[i]`` applies to the unsquared
374: (8) residual ``y[i] - y_hat[i]`` at ``x[i]``. Ideally the weights are
375: (8) chosen so that the errors of the products ``w[i]*y[i]`` all have the
376: (8) same variance. When using inverse-variance weighting, use
377: (8) ``w[i] = 1/sigma(y[i])``. The default value is None.
378: (4) cov : bool or str, optional
379: (8) If given and not `False`, return not just the estimate but also its
380: (8) covariance matrix. By default, the covariance are scaled by
381: (8) chi2/dof, where dof = M - (deg + 1), i.e., the weights are presumed
382: (8) to be unreliable except in a relative sense and everything is scaled
383: (8) such that the reduced chi2 is unity. This scaling is omitted if
384: (8) ``cov='unscaled'``, as is relevant for the case that the weights are
385: (8) w = 1/sigma, with sigma known to be a reliable estimate of the
386: (8) uncertainty.
387: (4) Returns
388: (4) -----
389: (4) p : ndarray, shape (deg + 1,) or (deg + 1, K)
390: (8) Polynomial coefficients, highest power first. If `y` was 2-D, the
391: (8) coefficients for `k`-th data set are in ``p[:,k]``.
392: (4) residuals, rank, singular_values, rcond
393: (8) These values are only returned if ``full == True``
394: (8) - residuals -- sum of squared residuals of the least squares fit
395: (8) - rank -- the effective rank of the scaled Vandermonde
396: (11) coefficient matrix
397: (8) - singular_values -- singular values of the scaled Vandermonde
398: (11) coefficient matrix
399: (8) - rcond -- value of `rcond`.
400: (8) For more details, see `numpy.linalg.lstsq`.
401: (4) V : ndarray, shape (M,M) or (M,M,K)
402: (8) Present only if ``full == False`` and ``cov == True``. The covariance
403: (8) matrix of the polynomial coefficient estimates. The diagonal of
404: (8) this matrix are the variance estimates for each coefficient. If y
405: (8) is a 2-D array, then the covariance matrix for the `k`-th data set
406: (8) are in ``V[:, :, k]``
407: (4) Warns
408: (4) -----
409: (4) RankWarning
410: (8) The rank of the coefficient matrix in the least-squares fit is
411: (8) deficient. The warning is only raised if ``full == False``.
412: (8) The warnings can be turned off by
413: (8) >>> import warnings
414: (8) >>> warnings.simplefilter('ignore', np.RankWarning)

```

431: (4) `polyfit` issues a `RankWarning` when the least-squares fit is badly
432: (4) conditioned. This implies that the best fit is not well-defined due
433: (4) to numerical error. The results may be improved by lowering the polynomial
434: (4) degree or by replacing `x` by `x` - `x`.mean(). The `rcond` parameter
435: (4) can also be set to a value smaller than its default, but the resulting
436: (4) fit may be spurious: including contributions from the small singular
437: (4) values can add numerical noise to the result.
438: (4) Note that fitting polynomial coefficients is inherently badly conditioned
439: (4) when the degree of the polynomial is large or the interval of sample
points
440: (4) is badly centered. The quality of the fit should always be checked in
these
441: (4) cases. When polynomial fits are not satisfactory, splines may be a good
442: (4) alternative.

449: (4) Examples
450: (4) -----
451: (4) >>> import warnings
452: (4) >>> x = np.array([0.0, 1.0, 2.0, 3.0, 4.0, 5.0])
453: (4) >>> y = np.array([0.0, 0.8, 0.9, 0.1, -0.8, -1.0])
454: (4) >>> z = np.polyfit(x, y, 3)
455: (4) >>> z
456: (4) array([ 0.08703704, -0.81349206,  1.69312169, -0.03968254]) # may vary
457: (4) It is convenient to use `poly1d` objects for dealing with polynomials:
458: (4) >>> p = np.poly1d(z)
459: (4) >>> p(0.5)
460: (4) 0.6143849206349179 # may vary
461: (4) >>> p(3.5)
462: (4) -0.34732142857143039 # may vary
463: (4) >>> p(10)
464: (4) 22.579365079365115 # may vary
465: (4) High-order polynomials may oscillate wildly:
466: (4) >>> with warnings.catch_warnings():
467: (4) ...     warnings.simplefilter('ignore', np.RankWarning)
468: (4) ...     p30 = np.poly1d(np.polyfit(x, y, 30))
469: (4) ...
470: (4) >>> p30(4)
471: (4) -0.80000000000000204 # may vary
472: (4) >>> p30(5)
473: (4) -0.9999999999999445 # may vary
474: (4) >>> p30(4.5)
475: (4) -0.10547061179440398 # may vary
476: (4) Illustration:
477: (4) >>> import matplotlib.pyplot as plt
478: (4) >>> xp = np.linspace(-2, 6, 100)
479: (4) >>> _ = plt.plot(x, y, '.', xp, p(xp), '-', xp, p30(xp), '--')
480: (4) >>> plt.ylim(-2,2)
481: (4) (-2, 2)
482: (4) >>> plt.show()

**Examples**

```

>>> from numpy.lib import recfunctions as rfn
>>> rfn.merge_arrays((np.array([1, 2]), np.array([10., 20., 30.])))
array([( 1, 10.), ( 2, 20.), (-1, 30.)],
      dtype=[('f0', '<i8'), ('f1', '<f8')])
>>> rfn.merge_arrays((np.array([1, 2], dtype=np.int64),
...                   np.array([10., 20., 30.])), usemask=False)
array([(1, 10.0), (2, 20.0), (-1, 30.0)],
      dtype=[('f0', '<i8'), ('f1', '<f8')])
>>> rfn.merge_arrays((np.array([1, 2]).view([('a', np.int64)]),
...                   np.array([10., 20., 30.])),
...                   usemask=False, asrecarray=True)
rec.array([( 1, 10.), ( 2, 20.), (-1, 30.)],
      dtype=[('a', '<i8'), ('f1', '<f8')])
```

**Notes**

```

-----
```

- \* Without a mask, the missing value will be filled with something, depending on what its corresponding type:
  - \* ``-1`` for integers
  - \* ``-1.0`` for floating point numbers
  - \* ``'-'`` for characters
  - \* ``'-1`` for strings
  - \* ``True`` for boolean values
- \* XXX: I just obtained these values empirically

```

633: (4)             """
634: (4)             Re-pack the fields of a structured array or dtype in memory.
635: (4)             The memory layout of structured datatypes allows fields at arbitrary
636: (4)             byte offsets. This means the fields can be separated by padding bytes,
637: (4)             their offsets can be non-monotonically increasing, and they can overlap.
638: (4)             This method removes any overlaps and reorders the fields in memory so they
639: (4)             have increasing byte offsets, and adds or removes padding bytes depending
640: (4)             on the `align` option, which behaves like the `align` option to
641: (4)             `numpy.dtype`.
642: (4)             If `align=False`, this method produces a "packed" memory layout in which
643: (4)             each field starts at the byte the previous field ended, and any padding
644: (4)             bytes are removed.
645: (4)             If `align=True`, this method produces an "aligned" memory layout in which
646: (4)             each field's offset is a multiple of its alignment, and the total itemsize
647: (4)             is a multiple of the largest alignment, by adding padding bytes as needed.
648: (4)             Parameters
649: (4)             -----
650: (4)             a : ndarray or dtype
651: (7)               array or dtype for which to repack the fields.
652: (4)             align : boolean
653: (7)               If true, use an "aligned" memory layout, otherwise use a "packed"

```

```

    """
    Converts an n-D unstructured array into an (n-1)-D structured array.
    The last dimension of the input array is converted into a structure, with
    number of field-elements equal to the size of the last dimension of the
    input array. By default all output fields have the input array's dtype,
    an output structured dtype with an equal number of fields-elements can be
    supplied instead.
    Nested fields, as well as each element of any subarray fields, all count
    towards the number of field-elements.
    Parameters
    -----
    arr : ndarray
        Unstructured array or dtype to convert.
    dtype : dtype, optional
        The structured dtype of the output array
    names : list of strings, optional
        If dtype is not supplied, this specifies the field names for the output
        dtype, in order. The field dtypes will be the same as the input array.
    align : boolean, optional
        Whether to create an aligned memory layout.
    copy : bool, optional
        See copy argument to `numpy.ndarray.astype`. If true, always return a
        copy. If false, and `dtype` requirements are satisfied, a view is
        returned.
    casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
        See casting argument of `numpy.ndarray.astype`. Controls what kind of
        data casting may occur.
    Returns
    -----
    structured : ndarray
        Structured array with fewer dimensions.
    Examples
    -----
    >>> from numpy.lib import recfunctions as rfn
    >>> dt = np.dtype([('a', 'i4'), ('b', 'f4,u2'), ('c', 'f4', 2)])
    >>> a = np.arange(20).reshape((4,5))

33: (4)          'arctanh'
34: (4)      ]
35: (0)      _ln2 = nx.log(2.0)
36: (0)      def _tocomplex(arr):
37: (4)          """Convert its input `arr` to a complex array.
38: (4)          The input is returned as a complex array of the smallest type that will
39: (4)          fit
40: (4)          the original data: types like single, byte, short, etc. become csingle,
41: (4)          while others become cdouble.
42: (4)          A copy of the input is always made.
43: (4)          Parameters
44: (4)          -----
45: (4)          arr : array
46: (4)          Returns
47: (4)          -----
48: (8)          array
49: (4)          An array with the same input data as the input but in complex form.
50: (4)          Examples
51: (4)          -----
52: (4)          First, consider an input of type short:
53: (4)          >>> a = np.array([1,2,3],np.short)
53: (4)          >>> ac = np.lib.scimath._tocomplex(a); ac
```

```

54: (4) array([1.+0.j, 2.+0.j, 3.+0.j], dtype=complex64)
55: (4) >>> ac.dtype
56: (4) dtype('complex64')
57: (4) If the input is of type double, the output is correspondingly of the
58: (4) complex double type as well:
59: (4) >>> b = np.array([1,2,3],np.double)
60: (4) >>> bc = np.lib.scimath._tocomplex(b); bc
61: (4) array([1.+0.j, 2.+0.j, 3.+0.j])
62: (4) >>> bc.dtype
63: (4) dtype('complex128')
64: (4) Note that even if the input was complex to begin with, a copy is still
65: (4) made, since the astype() method always copies:
66: (4) >>> c = np.array([1,2,3],np.csingle)
67: (4) >>> cc = np.lib.scimath._tocomplex(c); cc
68: (4) array([1.+0.j, 2.+0.j, 3.+0.j], dtype=complex64)
69: (4) >>> c *= 2; c
70: (4) array([2.+0.j, 4.+0.j, 6.+0.j], dtype=complex64)
71: (4) >>> cc
72: (4) array([1.+0.j, 2.+0.j, 3.+0.j], dtype=complex64)
73: (4) """

141: (0)      @array_function_dispatch(_unary_dispatcher)
142: (0)      def sqrt(x):
143: (4)          """
144: (4)          Compute the square root of x.
145: (4)          For negative input elements, a complex value is returned
146: (4)          (unlike `numpy.sqrt` which returns NaN).
147: (4)          Parameters
148: (4)          -----
149: (4)          x : array_like
150: (7)              The input value(s).
151: (4)          Returns
152: (4)          -----
153: (4)          out : ndarray or scalar
154: (7)              The square root of `x`. If `x` was a scalar, so is `out`,
155: (7)              otherwise an array is returned.
156: (4)          See Also
157: (4)          -----
158: (4)          numpy.sqrt
159: (4)          Examples
160: (4)          -----
161: (4)          For real, non-negative inputs this works just like `numpy.sqrt`:
162: (4)          >>> np.emath.sqrt(1)
163: (4)          1.0
164: (4)          >>> np.emath.sqrt([1, 4])
165: (4)          array([1., 2.])
166: (4)          But it automatically handles negative inputs:
167: (4)          >>> np.emath.sqrt(-1)
168: (4)          1j
169: (4)          >>> np.emath.sqrt([-1,4])
170: (4)          array([0.+1.j, 2.+0.j])
171: (4)          Different results are expected because:
172: (4)          floating point 0.0 and -0.0 are distinct.
173: (4)          For more control, explicitly use complex() as follows:
174: (4)          >>> np.emath.sqrt(complex(-4.0, 0.0))
175: (4)          2j
176: (4)          >>> np.emath.sqrt(complex(-4.0, -0.0))
177: (4)          -2j
178: (4)          """
179: (4)          x = _fix_real_lt_zero(x)
180: (4)          return nx.sqrt(x)
181: (0)          @array_function_dispatch(_unary_dispatcher)
182: (0)          def log(x):
183: (4)              """
184: (4)              Compute the natural logarithm of `x`.
185: (4)              Return the "principal value" (for a description of this, see `numpy.log`)
186: (4)              of :math:`\log_e(x)`. For real `x > 0`, this is a real number (`\log(0)``
187: (4)              returns ``-inf`` and ``\log(np.inf)`` returns ``inf``). Otherwise, the
188: (4)              complex principle value is returned.
189: (4)              Parameters
190: (4)              -----
191: (4)              x : array_like

```

```

192: (7)           The value(s) whose log is (are) required.
193: (4)           Returns
194: (4)
195: (4)           out : ndarray or scalar
196: (7)           The log of the `x` value(s). If `x` was a scalar, so is `out`,
197: (7)           otherwise an array is returned.

286: (0)             def log2(x):
287: (4)             """
288: (4)             Compute the logarithm base 2 of `x`.
289: (4)             Return the "principal value" (for a description of this, see
`numpy.log2`) of :math:`\log_2(x)`. For real `x > 0`, this is
290: (4)             a real number (`log2(0)` returns ``-inf`` and `log2(np.inf)` returns
`inf`). Otherwise, the complex principle value is returned.
291: (4)             Parameters
292: (4)             -----
293: (4)             x : array_like
294: (4)             The value(s) whose log base 2 is (are) required.
295: (4)             Returns
296: (4)             -----
297: (4)             out : ndarray or scalar
298: (4)             The log base 2 of the `x` value(s). If `x` was a scalar, so is `out`,
299: (4)             otherwise an array is returned.
300: (7)             See Also
301: (7)             -----
302: (4)             numpy.log2
303: (4)             Notes
304: (4)             -----
305: (4)             For a log2() that returns ``NAN`` when real `x < 0`, use `numpy.log2`
306: (4)             (note, however, that otherwise `numpy.log2` and this `log2` are
307: (4)             identical, i.e., both return ``-inf`` for `x = 0`, ``inf`` for `x = inf`,
308: (4)             and, notably, the complex principle value if ``x.imag != 0``).
309: (4)             Examples
310: (4)             -----
311: (4)             We set the printing precision so the example can be auto-tested:
312: (4)             >>> np.set_printoptions(precision=4)
313: (4)             >>> np.emath.log2(8)
314: (4)             3.0
315: (4)             >>> np.emath.log2([-4, -8, 8])
316: (4)             array([2.+4.5324j, 3.+4.5324j, 3.+0.j      ])
317: (4)             """
318: (4)
319: (4)
320: (4)             x = _fix_real_lt_zero(x)
321: (4)             return nx.log2(x)
322: (0)             def _power_dispatcher(x, p):
323: (4)             return (x, p)
324: (0)             @array_function_dispatch(_power_dispatcher)
325: (0)             def power(x, p):
326: (4)             """
327: (4)             Return x to the power p, ( $x^{**p}$ ).
328: (4)             If `x` contains negative values, the output is converted to the

```

```

329: (4)           complex domain.
330: (4)           Parameters
331: (4)
332: (4)           -----
333: (8)           x : array_like
334: (4)           The input value(s).
335: (8)           p : array_like of ints
336: (8)           The power(s) to which `x` is raised. If `x` contains multiple values,
337: (8)           `p` has to either be a scalar, or contain the same number of values
338: (8)           as `x`. In the latter case, the result is
339: (4)           ``x[0]**p[0], x[1]**p[1], ...``.
340: (4)           Returns
341: (4)
342: (8)           out : ndarray or scalar
343: (8)           The result of ``x**p``. If `x` and `p` are scalars, so is `out`,
344: (4)           otherwise an array is returned.

52: (4) indices : ndarray (Ni..., J, Nk...)
53: (8)     Indices to take along each 1d slice of `arr`. This must match the
54: (8)     dimension of arr, but dimensions Ni and Nj only need to broadcast
55: (8)     against `arr`.
56: (4) axis : int
57: (8)     The axis to take 1d slices along. If axis is None, the input array is
58: (8)     treated as if it had first been flattened to 1d, for consistency with
59: (8)     `sort` and `argsort`.
60: (4) Returns
61: (4) -----
62: (4) out: ndarray (Ni..., J, Nk...)
63: (8)     The indexed result.
64: (4) Notes
65: (4) -----
66: (4) This is equivalent to (but faster than) the following use of `ndindex` and
67: (4) `s_`, which sets each of ``ii`` and ``kk`` to a tuple of indices::
68: (8) Ni, M, Nk = a.shape[:axis], a.shape[axis], a.shape[axis+1:]
69: (8) J = indices.shape[axis] # Need not equal M
70: (8) out = np.empty(Ni + (J,) + Nk)
71: (8) for ii in ndindex(Ni):
72: (12)     for kk in ndindex(Nk):
73: (16)         a_1d      = a      [ii + s_[:,] + kk]
74: (16)         indices_1d = indices[ii + s_[:,] + kk]
75: (16)         out_1d    = out    [ii + s_[:,] + kk]
76: (16)         for j in range(J):
77: (20)             out_1d[j] = a_1d[indices_1d[j]]
78: (4) Equivalently, eliminating the inner loop, the last two lines would be::
79: (16)         out_1d[:] = a_1d[indices_1d]
80: (4) See Also
81: (4) -----
82: (4) take : Take along an axis, using the same indices for every 1d slice
83: (4) put_along_axis :
84: (8)     Put values into the destination array by matching 1d index and data
slices
85: (4) Examples
86: (4) -----
87: (4) For this sample array
88: (4) >>> a = np.array([[10, 30, 20], [60, 40, 50]])
89: (4) We can sort either by using sort directly, or argsort and this function
90: (4) >>> np.sort(a, axis=1)
91: (4) array([[10, 20, 30],
92: (11)      [40, 50, 60]])
93: (4) >>> ai = np.argsort(a, axis=1)
94: (4) >>> ai
95: (4) array([[0, 2, 1],
96: (11)      [1, 2, 0]])
97: (4) >>> np.take_along_axis(a, ai, axis=1)
98: (4) array([[10, 20, 30],
99: (11)      [40, 50, 60]])
100: (4) The same works for max and min, if you maintain the trivial dimension
101: (4) with ``keepdims``:
102: (4) >>> np.max(a, axis=1, keepdims=True)
103: (4) array([[30],
104: (11)      [60]])
105: (4) >>> ai = np.argmax(a, axis=1, keepdims=True)
106: (4) >>> ai
107: (4) array([[1],
108: (11)      [0]])
109: (4) >>> np.take_along_axis(a, ai, axis=1)
110: (4) array([[30],
111: (11)      [60]])
112: (4) If we want to get the max and min at the same time, we can stack the
113: (4) indices first
114: (4) >>> ai_min = np.argmin(a, axis=1, keepdims=True)

```

```

115: (4)                                     >>> ai_max = np.argmax(a, axis=1, keepdims=True)
116: (4)                                     >>> ai = np.concatenate([ai_min, ai_max], axis=1)
117: (4)                                     >>> ai
118: (4)                                     array([[0, 1],
119: (11)                                         [1, 0]])
120: (4)                                     >>> np.take_along_axis(a, ai, axis=1)
121: (4)                                     array([[10, 30],
122: (11)                                         [40, 60]])

        Apply a function repeatedly over multiple axes.
        `func` is called as `res = func(a, axis)`, where `axis` is the first
        element of `axes`. The result `res` of the function call must have
        either the same dimensions as `a` or one less dimension. If `res`
        has one less dimension than `a`, a dimension is inserted before
        `axis`. The call to `func` is then repeated for each axis in `axes`,

```

```

320: (4)           with `res` as the first argument.
321: (4)           Parameters
322: (4)           -----
323: (4)           func : function
324: (8)             This function must take two arguments, `func(a, axis)` .
325: (4)           a : array_like
326: (8)             Input array.
327: (4)           axes : array_like
328: (8)             Axes over which `func` is applied; the elements must be integers.
329: (4)           Returns
330: (4)           -----
331: (4)           apply_over_axis : ndarray
332: (8)             The output array. The number of dimensions is the same as `a` ,
333: (8)             but the shape can be different. This depends on whether `func` 
334: (8)             changes the shape of its output with respect to its input.
335: (4)           See Also
336: (4)           -----
337: (4)           apply_along_axis :
338: (8)             Apply a function to 1-D slices of an array along the given axis.
339: (4)           Notes
340: (4)           -----
341: (4)           This function is equivalent to tuple axis arguments to reorderable ufuncs
342: (4)           with keepdims=True. Tuple axis arguments to ufuncs have been available
since
343: (4)           version 1.7.0.
344: (4)           Examples
345: (4)           -----
346: (4)           >>> a = np.arange(24).reshape(2,3,4)
347: (4)           >>> a
348: (4)           array([[[ 0,  1,  2,  3],
349: (12)             [ 4,  5,  6,  7],
350: (12)             [ 8,  9, 10, 11]],
351: (11)             [[12, 13, 14, 15],

def expand_dims(a, axis):
    """
        Expand the shape of an array.
        Insert a new axis that will appear at the `axis` position in the expanded
        array shape.
        Parameters
        -----
        a : array_like
            Input array.
        axis : int or tuple of ints
            Position in the expanded axes where the new axis (or axes) is placed.
            .. deprecated:: 1.13.0
                Passing an axis where ``axis > a.ndim`` will be treated as
                ``axis == a.ndim``, and passing ``axis < -a.ndim - 1`` will
                be treated as ``axis == 0``. This behavior is deprecated.
            .. versionchanged:: 1.18.0
                A tuple of axes is now supported. Out of range axes as
                described above are now forbidden and raise an `AxisError`.
        Returns
        -----
        result : ndarray
            View of `a` with the number of dimensions increased.
        See Also
        -----
        squeeze : The inverse operation, removing singleton dimensions
        reshape : Insert, remove, and combine dimensions, and resize existing ones
        doc.indexing, atleast_1d, atleast_2d, atleast_3d
        Examples
        -----
        >>> x = np.array([1, 2])
        >>> x.shape
        (2,)
        The following is equivalent to ``x[np.newaxis, :]`` or ``x[np.newaxis]``:
        >>> y = np.expand_dims(x, axis=0)
        >>> y
        array([[1, 2]])
        >>> y.shape
        (1, 2)
        The following is equivalent to ``x[:, np.newaxis]``:
        >>> y = np.expand_dims(x, axis=1)
        >>> y
        array([[1],
               [2]])
        >>> y.shape
        (2, 1)
        ``axis`` may also be a tuple:
        >>> y = np.expand_dims(x, axis=(0, 1))
        >>> y
        array([[[1, 2]]])
        >>> y = np.expand_dims(x, axis=(2, 0))
        >>> y
        array([[[[1,
                  [2]]]]]
        Note that some examples may use ``None`` instead of ``np.newaxis``. These
        are the same objects:
        >>> np.newaxis is None
        True
        """
        if isinstance(a, matrix):

    """
    Kronecker product of two arrays.
    Computes the Kronecker product, a composite array made of blocks of the
    second array scaled by the first.
    Parameters
    -----
    a, b : array_like
    Returns
    -----
    out : ndarray
    See Also
    -----
    outer : The outer product
    Notes
    -----
    The function assumes that the number of dimensions of `a` and `b`
    are the same, if necessary prepending the smallest with ones.
    If ``a.shape = (r0,r1,...,rN)`` and ``b.shape = (s0,s1,...,sN)``,
    the Kronecker product has shape ``(r0*s0, r1*s1, ..., rN*sN)``.
    The elements are products of elements from `a` and `b`, organized
    explicitly by::
        kron(a,b)[k0,k1,...,kN] = a[i0,i1,...,iN] * b[j0,j1,...,jN]
    where::
        kt = it * st + jt, t = 0,...,N
    In the common 2-D case (N=1), the block structure can be visualized::
        [[ a[0,0]*b, a[0,1]*b, ... , a[0,-1]*b ],
         [ ...           ...       ],
         [ a[-1,0]*b, a[-1,1]*b, ... , a[-1,-1]*b ]]

906: (4)          result = _nx.multiply(a_arr, b_arr, subok=(not is_any_mat))
907: (4)          result = result.reshape(_nx.multiply(as_, bs))
908: (4)          return result if not is_any_mat else matrix(result, copy=False)
909: (0)          def _tile_dispatcher(A, reps):
910: (4)              return (A, reps)
911: (0)          @array_function_dispatch(_tile_dispatcher)
912: (0)          def tile(A, reps):
913: (4)              """
914: (4)              Construct an array by repeating A the number of times given by reps.
915: (4)              If `reps` has length ``d``, the result will have dimension of
916: (4)              ``max(d, A.ndim)``.
917: (4)              If ``A.ndim < d``, `A` is promoted to be d-dimensional by prepending new
918: (4)              axes. So a shape (3,) array is promoted to (1, 3) for 2-D replication,
919: (4)              or shape (1, 1, 3) for 3-D replication. If this is not the desired
920: (4)              behavior, promote `A` to d-dimensions manually before calling this
921: (4)              function.
922: (4)              If ``A.ndim > d``, `reps` is promoted to `A`.ndim by pre-pending 1's to
923: (4)              it.
924: (4)              Thus for an `A` of shape (2, 3, 4, 5), a `reps` of (2, 2) is treated as
925: (4)              (1, 1, 2, 2).
926: (4)              Note : Although tile may be used for broadcasting, it is strongly
927: (4)              recommended to use numpy's broadcasting operations and functions.
928: (4)              Parameters
929: (4)              -----
930: (8)              A : array_like
931: (4)                  The input array.
932: (8)              reps : array_like
933: (4)                  The number of repetitions of `A` along each axis.

```

```

933: (4)          Returns
934: (4)          -----
935: (4)          c : ndarray
936: (8)          The tiled output array.
937: (4)          See Also
938: (4)          -----
939: (4)          repeat : Repeat elements of an array.
940: (4)          broadcast_to : Broadcast an array to a new shape
941: (4)          Examples
942: (4)          -----

53: (4)             -----
54: (4)             ``as_strided`` creates a view into the array given the exact strides
55: (4)             and shape. This means it manipulates the internal data structure of
56: (4)             ndarray and, if done incorrectly, the array elements can point to
57: (4)             invalid memory and can corrupt results or crash your program.
58: (4)             It is advisable to always use the original ``x.strides`` when
59: (4)             calculating new strides to avoid reliance on a contiguous memory
60: (4)             layout.
61: (4)             Furthermore, arrays created with this function often contain self
62: (4)             overlapping memory, so that two elements are identical.
63: (4)             Vectorized write operations on such arrays will typically be
64: (4)             unpredictable. They may even give different results for small, large,
65: (4)             or transposed arrays.
66: (4)             Since writing to these arrays has to be tested and done with great
67: (4)             care, you may want to use ``writeable=False`` to avoid accidental write
68: (4)             operations.
69: (4)             For these reasons it is advisable to avoid ``as_strided`` when
70: (4)             possible.
71: (4)             """
72: (4)             x = np.array(x, copy=False, subok=subok)

90: (4)             """
91: (4)             Create a sliding window view into the array with the given window shape.
92: (4)             Also known as rolling or moving window, the window slides across all
93: (4)             dimensions of the array and extracts subsets of the array at all window
94: (4)             positions.
95: (4)             .. versionadded:: 1.20.0
96: (4)         Parameters
97: (4)             -----
98: (4)             x : array_like
99: (8)             Array to create the sliding window view from.
100: (4)             window_shape : int or tuple of int
101: (8)             Size of window over each axis that takes part in the sliding window.
102: (8)             If `axis` is not present, must have same length as the number of input
103: (8)             array dimensions. Single integers `i` are treated as if they were the
104: (8)             tuple `(i,)`.
105: (4)             axis : int or tuple of int, optional
106: (8)             Axis or axes along which the sliding window is applied.
107: (8)             By default, the sliding window is applied to all axes and
108: (8)             `window_shape[i]` will refer to axis `i` of `x`.
109: (8)             If `axis` is given as a `tuple of int`, `window_shape[i]` will refer
to
110: (8)             the axis `axis[i]` of `x`.
111: (8)             Single integers `i` are treated as if they were the tuple `(i,)`.
112: (4)             subok : bool, optional
113: (8)             If True, sub-classes will be passed-through, otherwise the returned
114: (8)             array will be forced to be a base-class array (default).
115: (4)             writeable : bool, optional
116: (8)             When true, allow writing to the returned view. The default is false,
117: (8)             as this should be used with caution: the returned view contains the
118: (8)             same memory location multiple times, so writing to one location will
119: (8)             cause others to change.
120: (4)         Returns
121: (4)             -----
122: (4)             view : ndarray
123: (8)             Sliding window view of the array. The sliding window dimensions are
124: (8)             inserted at the end, and the original dimensions are trimmed as
125: (8)             required by the size of the sliding window.
126: (8)             That is, ``view.shape = x_shape_trimmed + window_shape``, where
127: (8)             ``x_shape_trimmed`` is ``x.shape`` with every entry reduced by one
less
128: (8)             than the corresponding window size.
129: (4)         See Also
130: (4)             -----
131: (4)             lib.stride_tricks.as_strided: A lower-level and less safe routine for
132: (8)                 creating arbitrary views from custom shape and strides.
133: (4)             broadcast_to: broadcast an array to a given shape.
134: (4)         Notes
135: (4)             -----
136: (4)             For many applications using a sliding window view can be convenient, but
137: (4)             potentially very slow. Often specialized solutions exist, for example:
138: (4)             - `scipy.signal.fftconvolve`
139: (4)             - filtering functions in `scipy.ndimage`
140: (4)             - moving window functions provided by
141: (6)                 `bottleneck <https://github.com/pydata/bottleneck>`_.
142: (4)             As a rough estimate, a sliding window approach with an input size of `N`
143: (4)             and a window size of `W` will scale as `O(N*W)` where frequently a special
144: (4)             algorithm can achieve `O(N)`. That means that the sliding window variant
for a window size of 100 can be a 100 times slower than a more specialized
145: (4)

```

SANJOYNATHQHENOMENOLOGYGEOMETRIFYINGTRIGONOMETRY\_combined\_python\_files\_20\_chars.txt

```

146: (4)           version.
147: (4)           Nevertheless, for small window sizes, when no custom algorithm exists, or
148: (4)           as a prototyping and developing tool, this function can be a good
solution.
149: (4)           Examples
150: (4)           -----
151: (4)           >>> x = np.arange(6)
152: (4)           >>> x.shape
153: (4)           (6,)
154: (4)           >>> v = sliding_window_view(x, 3)
155: (4)           >>> v.shape
156: (4)           (4, 3)
157: (4)           >>> v
158: (4)           array([[0, 1, 2],
159: (11)             [1, 2, 3],
160: (11)             [2, 3, 4],
161: (11)             [3, 4, 5]])
162: (4)           This also works in more dimensions, e.g.
163: (4)           >>> i, j = np.ogrid[:3, :4]
164: (4)           >>> x = 10*i + j
165: (4)           >>> x.shape
166: (4)           (3, 4)
167: (4)           >>> x
168: (4)           array([[ 0,  1,  2,  3],
169: (11)             [10, 11, 12, 13],
170: (11)             [20, 21, 22, 23]])
171: (4)           >>> shape = (2,2)
172: (4)           >>> v = sliding_window_view(x, shape)
173: (4)           >>> v.shape
174: (4)           (2, 3, 2, 2)
175: (4)           >>> v
176: (4)           array([[[[ 0,  1,
177: (13)             [10, 11],
178: (12)               [[ 1,  2],
179: (13)                 [11, 12]],
180: (12)                 [[ 2,  3],
181: (13)                   [12, 13]]],
182: (11)                   [[[10, 11],
183: (13)                     [20, 21]],
184: (12)                     [[11, 12],
185: (13)                       [21, 22]],
186: (12)                       [[12, 13],
187: (13)                         [22, 23]]]])
188: (4)           The axis can be specified explicitly:
189: (4)           >>> v = sliding_window_view(x, 3, 0)
190: (4)           >>> v.shape
191: (4)           (1, 4, 3)
192: (4)           >>> v
193: (4)           array([[[ 0, 10, 20],
194: (12)             [ 1, 11, 21],
195: (12)             [ 2, 12, 22],
196: (12)             [ 3, 13, 23]]])
197: (4)           The same axis can be used several times. In that case, every use reduces
198: (4)           the corresponding original dimension:
199: (4)           >>> v = sliding_window_view(x, (2, 3), (1, 1))
200: (4)           >>> v.shape
201: (4)           (3, 1, 2, 3)
202: (4)           >>> v
203: (4)           array([[[[ 0,  1,  2],
204: (13)             [ 1,  2,  3]]],
205: (11)               [[[10, 11, 12],
206: (13)                 [11, 12, 13]]],
207: (11)                 [[[20, 21, 22],
208: (13)                   [21, 22, 23]]]])
209: (4)           Combining with stepped slicing (`::step`), this can be used to take
sliding
210: (4)           views which skip elements:
211: (4)           >>> x = np.arange(7)
212: (4)           >>> sliding_window_view(x, 5)[:, ::2]
```

519: (4)          -----
520: (4)          x : array_like, shape (N,)
521: (8)              An array containing the x coordinates of the points to be
522: (8)              histogrammed.
523: (4)          y : array_like, shape (N,)
524: (8)              An array containing the y coordinates of the points to be
525: (8)              histogrammed.
526: (4)          bins : int or array_like or [int, int] or [array, array], optional
527: (8)              The bin specification:
528: (10)                 * If int, the number of bins for the two dimensions (nx=ny=bins).
529: (10)                 * If array_like, the bin edges for the two dimensions
530: (12)                     (x_edges=y_edges=bins).
531: (10)                 * If [int, int], the number of bins in each dimension
532: (12)                     (nx, ny = bins).
533: (10)                 * If [array, array], the bin edges in each dimension
534: (12)                     (x_edges, y_edges = bins).
535: (10)                 * A combination [int, array] or [array, int], where int
536: (12)                     is the number of bins and array is the bin edges.
537: (4)          range : array_like, shape(2,2), optional

```

```

538: (8)           The leftmost and rightmost edges of the bins along each dimension
539: (8)           (if not specified explicitly in the `bins` parameters):
540: (8)           ``[[xmin, xmax], [ymin, ymax]]``. All values outside of this range
541: (8)           will be considered outliers and not tallied in the histogram.
542: (4)           density : bool, optional
543: (8)           If False, the default, returns the number of samples in each bin.
544: (8)           If True, returns the probability *density* function at the bin,
545: (8)           ``bin_count / sample_count / bin_area``.
546: (4)           weights : array_like, shape(N,), optional
547: (8)           An array of values ``w_i`` weighing each sample ``(x_i, y_i)``.
548: (8)           Weights are normalized to 1 if `density` is True. If `density` is
549: (8)           False, the values of the returned histogram are equal to the sum of
550: (8)           the weights belonging to the samples falling into each bin.
551: (4)           Returns
552: (4)           -----
553: (4)           H : ndarray, shape(nx, ny)
554: (8)           The bi-dimensional histogram of samples `x` and `y`. Values in `x`
555: (8)           are histogrammed along the first dimension and values in `y` are
556: (8)           histogrammed along the second dimension.
557: (4)           xedges : ndarray, shape(nx+1,)
558: (8)           The bin edges along the first dimension.
559: (4)           yedges : ndarray, shape(ny+1,)
560: (8)           The bin edges along the second dimension.
561: (4)           See Also
562: (4)           -----
563: (4)           histogram : 1D histogram
564: (4)           histogramdd : Multidimensional histogram
565: (4)           Notes
566: (4)           -----
567: (4)           When `density` is True, then the returned histogram is the sample
568: (4)           density, defined such that the sum over bins of the product
569: (4)           ``bin_value * bin_area`` is 1.
570: (4)           Please note that the histogram does not follow the Cartesian convention
571: (4)           where `x` values are on the abscissa and `y` values on the ordinate
572: (4)           axis. Rather, `x` is histogrammed along the first dimension of the
573: (4)           array (vertical), and `y` along the second dimension of the array
574: (4)           (horizontal). This ensures compatibility with `histogramdd`.
575: (4)           Examples
576: (4)           -----
577: (4)           >>> from matplotlib.image import NonUniformImage
578: (4)           >>> import matplotlib.pyplot as plt
579: (4)           Construct a 2-D histogram with variable bin width. First define the bin
580: (4)           edges:
581: (4)           >>> xedges = [0, 1, 3, 5]
582: (4)           >>> yedges = [0, 2, 3, 4, 6]
583: (4)           Next we create a histogram H with random bin content:
584: (4)           >>> x = np.random.normal(2, 1, 100)
585: (4)           >>> y = np.random.normal(1, 1, 100)
586: (4)           >>> H, xedges, yedges = np.histogram2d(x, y, bins=(xedges, yedges))
587: (4)           >>> # Histogram does not follow Cartesian convention (see Notes),
588: (4)           >>> # therefore transpose H for visualization purposes.
589: (4)           >>> H = H.T
590: (4)           :func:`imshow <matplotlib.pyplot.imshow>` can only display square bins:
591: (4)           >>> fig = plt.figure(figsize=(7, 3))
592: (4)           >>> ax = fig.add_subplot(131, title='imshow: square bins')
593: (4)           >>> plt.imshow(H, interpolation='nearest', origin='lower',
594: (4)               ...          extent=[xedges[0], xedges[-1], yedges[0], yedges[-1]])
595: (4)           <matplotlib.image.AxesImage object at 0x...>
596: (4)           :func:`pcolormesh <matplotlib.pyplot.pcormesh>` can display actual
edges:
597: (4)           >>> ax = fig.add_subplot(132, title='pcolormesh: actual edges',
598: (4)               ...          aspect='equal')
599: (4)           >>> X, Y = np.meshgrid(xedges, yedges)
600: (4)           >>> ax.pcormesh(X, Y, H)
601: (4)           <matplotlib.collections.QuadMesh object at 0x...>
602: (4)           :class:`NonUniformImage <matplotlib.image.NonUniformImage>` can be used to
603: (4)           display actual bin edges with interpolation:
604: (4)           >>> ax = fig.add_subplot(133, title='NonUniformImage: interpolated',
605: (4)               ...          aspect='equal', xlim=xedges[[0, -1]], ylim=yedges[[0, -1]])

```

```

606: (4)             >>> im = NonUniformImage(ax, interpolation='bilinear')
607: (4)             >>> xcenters = (xedges[:-1] + xedges[1:]) / 2
608: (4)             >>> ycenters = (yedges[:-1] + yedges[1:]) / 2
609: (4)             >>> im.set_data(xcenters, ycenters, H)
610: (4)             >>> ax.add_image(im)
611: (4)             >>> plt.show()
612: (4)             It is also possible to construct a 2-D histogram without specifying bin
613: (4)             edges:
614: (4)             >>> # Generate non-symmetric test data
615: (4)             >>> n = 10000
616: (4)             >>> x = np.linspace(1, 100, n)
617: (4)             >>> y = 2*np.log(x) + np.random.rand(n) - 0.5
618: (4)             >>> # Compute 2d histogram. Note the order of x/y and xedges/yedges
619: (4)             >>> H, yedges, xedges = np.histogram2d(y, x, bins=20)
620: (4)             Now we can plot the histogram using
621: (4)             :func:`pcolormesh <matplotlib.pyplot.pcolormesh>`, and a
622: (4)             :func:`hexbin <matplotlib.pyplot.hexbin>` for comparison.
623: (4)             >>> # Plot histogram using pcolormesh
624: (4)             >>> fig, (ax1, ax2) = plt.subplots(ncols=2, sharey=True)
625: (4)             >>> ax1.pcolormesh(xedges, yedges, H, cmap='rainbow')
626: (4)             >>> ax1.plot(x, 2*np.log(x), 'k-')
627: (4)             >>> ax1.set_xlim(x.min(), x.max())
628: (4)             >>> ax1.set_ylim(y.min(), y.max())
629: (4)             >>> ax1.set_xlabel('x')
630: (4)             >>> ax1.set_ylabel('y')
631: (4)             >>> ax1.set_title('histogram2d')
632: (4)             >>> ax1.grid()
633: (4)             >>> # Create hexbin plot for comparison
634: (4)             >>> ax2.hexbin(x, y, gridsize=20, cmap='rainbow')
635: (4)             >>> ax2.plot(x, 2*np.log(x), 'k-')

656: (4)             """
657: (4)             Return the indices to access (n, n) arrays, given a masking function.
658: (4)             Assume `mask_func` is a function that, for a square array a of size
659: (4)             ````(n, n)```` with a possible offset argument `k`, when called as
660: (4)             ````mask_func(a, k)```` returns a new array with zeros in certain locations
661: (4)             (functions like `triu` or `tril` do precisely this). Then this function
662: (4)             returns the indices where the non-zero values would be located.
663: (4)             Parameters
664: (4)             -----
665: (4)             n : int
666: (8)                 The returned indices will be valid to access arrays of shape (n, n).
667: (4)             mask_func : callable
668: (8)                 A function whose call signature is similar to that of `triu`, `tril`.
669: (8)                 That is, ````mask_func(x, k)```` returns a boolean array, shaped like `x`.
670: (8)                 `k` is an optional argument to the function.
671: (4)             k : scalar
672: (8)                 An optional argument which is passed through to `mask_func`. Functions
673: (8)                 like `triu`, `tril` take a second argument that is interpreted as an
674: (8)                 offset.

          .. warning::
              This function is identical to :py:meth:`ast.literal_eval` and
              has the same security implications. It may not always be safe
              to evaluate large input strings.

          Parameters
          -----
          source : str
              The string to evaluate.
          Returns
          -----
          obj : object
              The result of evaluating `source`.
          Raises
          -----
          SyntaxError
              If the code has invalid Python syntax, or if it contains
              non-literal code.
          Examples
          -----
          >>> np.safe_eval('1')
          1
          >>> np.safe_eval('[1, 2, 3]')
          [1, 2, 3]
          >>> np.safe_eval('{"foo": ("bar", 10.0)}')
          {'foo': ('bar', 10.0)}
          >>> np.safe_eval('import os')
          Traceback (most recent call last):
          ...
          SyntaxError: invalid syntax
          >>> np.safe_eval('open("/home/user/.ssh/id_dsa").read()')
          Traceback (most recent call last):
          ...
          ValueError: malformed node or string: <_ast.Call object at 0x...>
          """
          import ast
          return ast.literal_eval(source)
      def _median_nancheck(data, result, axis):
          """
          Utility function to check median result from data for NaN values at the
          and return NaN in that case. Input result can also be a MaskedArray.

          Parameters
          -----
          data : array
              Sorted input data to median function
          result : Array or MaskedArray
              Result of median function.
          axis : int
              Axis along which the median was computed.
          Returns
          -----
          result : scalar or ndarray
              Median or NaN in axes which contained NaN in the input. If the input
              was an array, NaN will be inserted in-place. If a scalar, either the
              input itself or a scalar NaN.
          """

## File 225 - \_datasource.py:

```

1: (0)         """A file interface for handling local and remote data files.
2: (0)         The goal of datasource is to abstract some of the file system operations
3: (0)         when dealing with data files so the researcher doesn't have to know all the
4: (0)         low-level details. Through datasource, a researcher can obtain and use a
5: (0)         file with one function call, regardless of location of the file.
6: (0)         DataSource is meant to augment standard python libraries, not replace them.
7: (0)         It should work seamlessly with standard file IO operations and the os
8: (0)         module.
9: (0)         DataSource files can originate locally or remotely:
10: (0)          - local files : '/home/guido/src/local/data.txt'
11: (0)          - URLs (http, ftp, ...) : 'http://www.scipy.org/not/real/data.txt'
12: (0)         DataSource files can also be compressed or uncompressed. Currently only
13: (0)         gzip, bz2 and xz are supported.
14: (0)         Example::
15: (4)             >>> # Create a DataSource, use os.curdir (default) for local storage.
16: (4)             >>> from numpy import DataSource
17: (4)             >>> ds = DataSource()
18: (4)
19: (4)             >>> # Open a remote file.
20: (4)             >>> # DataSource downloads the file, stores it locally in:
21: (4)                 './www.google.com/index.html'
22: (4)             >>> # opens the file and returns a file object.
23: (4)             >>> fp = ds.open('http://www.google.com/') # doctest: +SKIP
24: (4)
25: (4)             >>> # Use the file as you normally would
26: (4)             >>> fp.read() # doctest: +SKIP
27: (4)             >>> fp.close() # doctest: +SKIP
28: (0)
29: (0)         """

class Repository (DataSource):
    """
        Repository(baseurl, destpath='.')
        A data repository where multiple DataSource's share a base
        URL/directory.
        `Repository` extends `DataSource` by prepending a base URL (or
        directory) to all the files it handles. Use `Repository` when you will
        be working with multiple files from one base URL. Initialize
        `Repository` with the base URL, then refer to each file by its filename
        only.
    Parameters
    -----
    baseurl : str
        Path to the local directory or remote location that contains the
        data files.
    destpath : str or None, optional
        Path to the directory where the source file gets downloaded to for
        use. If `destpath` is None, a temporary directory will be created.
        The default path is the current directory.
    Examples
    -----
    To analyze all files in the repository, do something like this
    (note: this is not self-contained code):::
        >>> repos = np.lib._datasource.Repository('/home/user/data/dir/')
        >>> for filename in filelist:
            ...     fp = repos.open(filename)
            ...     fp.analyze()

```

```

409: (8)           ...     fp.close()
410: (4)           Similarly you could use a URL for a repository:
411: (8)           >>> repos = np.lib._datasource.Repository('http://www.xyz.edu/data')
412: (4)
413: (4)           def __init__(self, baseurl, destpath=os.curdir):

        Object to validate a list of strings to use as field names.
        The strings are stripped of any non alphanumeric character, and spaces
        are replaced by '_'. During instantiation, the user can define a list
        of names to exclude, as well as a list of invalid characters. Names in
        the exclusion list are appended a '_' character.
        Once an instance has been created, it can be called with a list of
        names, and a list of valid names will be created. The `__call__`
        method accepts an optional keyword "default" that sets the default name
        in case of ambiguity. By default this is 'f', so that names will
        default to `f0`, `f1`, etc.
        Parameters
        -----
        excludelist : sequence, optional
            A list of names to exclude. This list is appended to the default
            list ['return', 'file', 'print']. Excluded names are appended an
            underscore: for example, `file` becomes `file_` if supplied.
        deletechars : str, optional
            A string combining invalid characters that must be deleted from the
            names.
        case_sensitive : {True, False, 'upper', 'lower'}, optional
            * If True, field names are case-sensitive.
            * If False or 'upper', field names are converted to upper case.
            * If 'lower', field names are converted to lower case.
            The default value is True.
        replace_space : '_', optional
            Character(s) used in replacement of white spaces.
        Notes
        -----
        Calling an instance of `NameValidator` is the same as calling its
        method `validate`.
        Examples
        -----
        >>> validator = np.lib._iotoools.NameValidator()
        >>> validator(['file', 'field2', 'with space', 'CaSe'])
        ('file_', 'field2', 'with_space', 'CaSe')
        >>> validator = np.lib._iotoools.NameValidator(excludelist=['excl'],
        ...                                              deletechars='q',
        ...                                              case_sensitive=False)
        >>> validator(['excl', 'field2', 'no_q', 'with space', 'CaSe'])
        ('EXCL', 'FIELD2', 'NO_Q', 'WITH_SPACE', 'CASE')
        """

      -----
      func : function
          Function used for the conversion.
      default : any
          Default value to return when the input corresponds to a missing
          value.
      type : type
          Type of the output.
      _status : int
          Integer representing the order of the conversion.
      _mapper : sequence of tuples
          Sequence of tuples (dtype, function, default value) to evaluate in
          order.
      _locked : bool
          Holds `locked` parameter.

      Parameters
      -----
      dtype_or_func : {None, dtype, function}, optional
          If a `dtype`, specifies the input data type, used to define a basic
          function and a default value for missing data. For example, when
          `dtype` is float, the `func` attribute is set to `float` and the
          default value to `np.nan`. If a function, this function is used to
          convert a string to another object. In this case, it is recommended
          to give an associated default value as input.
      default : any, optional
          Value to return by default, that is, when the string to be
          converted is flagged as missing. If not given, `StringConverter`
          tries to supply a reasonable default value.
      missing_values : {None, sequence of str}, optional
          ``None`` or sequence of strings indicating a missing value. If
          ``None``
          then missing values are indicated by empty entries. The default is
          ``None``.
      locked : bool, optional
          Whether the StringConverter should be locked to prevent automatic
          upgrade or not. Default is False.

self._find_map_entry(dtype)
504: (12)
505: (16)

The input function (or sequence of functions) and its associated
default value (if any) is inserted in penultimate position of the
mapper. The corresponding type is estimated from the dtype of the
default value.

Parameters
-----
func : var
Function, or sequence of functions

Examples
-----
>>> import dateutil.parser
>>> import datetime
>>> dateparser = dateutil.parser.parse
>>> defaultdate = datetime.date(2000, 1, 1)
>>> StringConverter.upgrade_mapper(dateparser, default=defaultdate)

575: (8) converters in order. First the `func` method of the
576: (8) `StringConverter` instance is tried, if this fails other available
577: (8) converters are tried. The order in which these other converters
578: (8) are tried is determined by the `_status` attribute of the instance.
579: (8) Parameters
580: (8) -----
581: (8) value : str
582: (12)     The string to convert.
583: (8) Returns
584: (8) -----
585: (8) out : any
586: (12)     The result of converting `value` with the appropriate converter.
587: (8)
588: (8)     self._checked = True
589: (8) try:
590: (12)     return self._strict_call(value)
591: (8) except ValueError:
592: (12)     self._do_upgrade()
593: (12)     return self.upgrade(value)
594: (4) def iterupgrade(self, value):
595: (8)     self._checked = True
596: (8)     if not hasattr(value, '__iter__'):
597: (12)         value = (value,)
598: (8)     _strict_call = self._strict_call
599: (8) try:
600: (12)     for _m in value:
601: (16)         _strict_call(_m)
602: (8)     except ValueError:
603: (12)         self._do_upgrade()
604: (12)         self.iterupgrade(value)
605: (4) def update(self, func, default=None, testing_value=None,
606: (15)     missing_values='', locked=False):
607: (8)
608: (8)     Set StringConverter attributes directly.
609: (8) Parameters
610: (8) -----
611: (8) func : function
612: (12)     Conversion function.
613: (8) default : any, optional
614: (12)     Value to return by default, that is, when the string to be
615: (12)     converted is flagged as missing. If not given,
616: (12)     `StringConverter` tries to supply a reasonable default value.
617: (8) testing_value : str, optional
618: (12)     A string representing a standard input value of the converter.
619: (12)     This string is used to help defining a reasonable default
620: (12)     value.
621: (8) missing_values : {sequence of str, None}, optional
622: (12)     Sequence of strings indicating a missing value. If ``None``, then
623: (12)     the existing `missing_values` are cleared. The default is ````.
624: (8) locked : bool, optional
625: (12)     Whether the StringConverter should be locked to prevent
626: (12)     automatic upgrade or not. Default is False.
627: (8) Notes
628: (8) -----
629: (8)     `update` takes the same parameters as the constructor of
630: (8)     `StringConverter`, except that `func` does not accept a `dtype`-
631: (8)     whereas `dtype_or_func` in the constructor does.
632: (8)
